Now ore minerals may be deposited in a fissure either (1) by meteoric waters that, having obtained their mineral content by leaching country rock, have entered the fissure from above or by seeping in from the sides, or (2) by hot waters (origin not stated) that have arisen from below, bringing ore minerals from an unknown source. Deposits of the first class are superficial in character, and, though sometimes extending hundreds of feet in depth, are likely to be rather shallow, and to lose value somewhat abruptly. They are characterized by low temperature and pressure minerals, and by the lack of certain alterations of the wall rock found in deposits of the second class.

Persistence in Depth

Modern theories of ore formation regard most of our veins as the result of precipitation by solutions ascending from great depths. While it is true that ores of this class do eventually grow poorer with deep mining, and while it is true this diminution in values varies so greatly from place to place that prophesying its results is impossible, the fact remains that such changes are usually gradual. Moreover, in some ore change in kind of ore usually precedes disappearance of mineralization.

The vein under consideration contains minerals characteristic of considerable pressure and temperature; it contains none of the minerals commonly the result of precipitation near the surface; and its walls are silicified and sericitized in a way that seems certainly the result of very hot solutions. It is therefore probable that it has been formed by waters ascending from great depths, and not by shallow infiltrations, and that its variations in depth will be similar to those of other veins formed by deep-seated processes. In the present workings the chief ore minerals are galena and tetrahedrite, the latter, here as so often, being richer in silver. Zinc is of minor importance. Experience teaches, however, that tetrahedrite usually does not reach as far in depth as galena, and that galena itself sooner or later gives place to sphalerite in most veins, but that these changes are gradual.

The conclusions drawn were: (1) there is no reason to expect the vein suddenly to become barren; (2) there is good reason to expect that at some depth silver will decrease because of loss of tetrahedrite, and that in-

creased proportions of zinc will change the value of the ore; (3) it is impossible to foretell the depth at which these changes will take place—hundreds of feet mark their limits in some districts, thousands of feet in others, and there is no local experience to furnish a guide.

It should be noted that these conclusions are based upon such 'theoretical' matters as critical minerals and alterations of the wall rock combined with empirical rules of experience, and that even then there is left a large element of uncertainty. But even with this uncertainty the conclusions are not without practical value. They show that there is a 'mining chance' justifying considerable expense for further exploration in depth, but they also emphasize the possible complications involved in abandoning the vein and running a long tunnel to meet it at great depths.

Effects of Secondary Enrichment

Any part of the value of the ore in the present workings due to secondary enrichment by descending waters is sure to disappear at comparatively shallow depths, and it is therefore of importance to determine the extent to which this process has been effective. Oxidation and leaching of the upper part of an orebody are prerequisite to the deposition of secondary sulphides at the water-level. This vein shows no oxidized capping, although it outcrops well on the top of a hill where recent river erosion has not been active, and it might be assumed that in this particular deposit there has been little or no oxidation and leaching of the orebody, and that therefore there has been no deposition of secondary sulphides. Such a theory is hardly tenable in view of the unmistakable evidences of glaciation found at the outcrops. It is probable that the sulphides reach to the surface, not because there has never been oxidation, but because the oxidized cap has been eroded by the ice-sheet. Moreover it is probable that the sulphides now outcropping at one time lay beneath the oxidized zone, and were secondarily enriched by waters descending therefrom. A careful study of the ore itself both in hand specimen and with the microscope, supports this view.

Galena, tetrahedrite, pyrite, and the gangue minerals are invariably intergrown in a manner indicative of simultaneous and primary deposition. Native silver, on the other hand, is found coating these other sulphides, and forming minute veinlets in them, an occurrence surely meaning secondary deposition; and probably by descending waters. Both theory and experience tell us that hot ascending waters are not likely to deposit films of native silver free from gangue or metallic sulphides.

The native silver, therefore, is likely to disappear at comparatively shallow depths, and the value of the ore to decrease correspondingly. Unfortunately it is difficult to give figures indicating the exact amount of this loss, for it is important to tell what proportion of the value of the ore where sampled is due to this particular mineral. Mineral separation and double assays of all the samples would answer the question roughly, but the expense would be prohibitive. Study of the faces sampled showed that native silver is not an essential mineral in the ore, so the conclusion is warranted that the value of the vein as at present developed is to a very small extent due to secondary enrichment.

Faulting

Displacements of a vein, even when not causing permanent loss of the orebody, entail additional expense in exploration, and often interfere with the plans for economical mining. A thorough examination of the surface was therefore undertaken to determine the possibility of the vein being disturbed in depth by intersecting faults. The well defined character of the sedimentary beds facilitated this work, and it was comparatively easy to ascertain that the areal distribution of the rocks was so conformable to the expectations based upon their depth and strike that faulting of serious extent is out of the question near the vein.

Some distance from the outcrop, however, there is a sharp depression with all of the ear-marks of a fault valley, and on the other side of this valley outcrop rocks which, according to the dip, should be thousands of feet below the surface. The valley evidently lies along a displacement so extensive and of such direction that its intersection with the vein would mean permanent loss of the ore. Unfortunately, the actual fault plane is concealed by the débris in the valley, and neither the direction nor the amount of dip is determinable. It is therefore necessary to fall back upon the slight knowledge available of the geodynamics of the district for a clue to the most probable direction of the fault plane. It so happens that even under the most unfavorable assumptions no projection of this fault will cut the vein at less than 1500 ft. in depth, so that our uncertainties in regard to it are not of great importance.

Summary

In view of the foregoing, it appears that the 'mining chance' in this property is excellent. Sudden change to unfavorable conditions with depth and interference of extensive faulting are extremely improbable; the vein is apparently the result of extensive fissuring and deep seated deposition, and not dependent upon localized conditions; loss of value due to disappearance of secondarily enriched ore will take place, but it will be slight; change in character and value of ore due to primary differentiation in depth is of course to be expected, but there is no indication that it will be especially sudden or more harmful than in other deposits of like character.

In spite of the favorable conditions for study in this particular deposit, there is still a deplorable indefiniteness about some of the conclusions, and there is always the possibility of meeting a condition as disturbing to geological views as was the persistence in depth of the chalcocite at Butte. Nevertheless the geological investigation has taken the investment out of the realms of mere chance. It has pointed out that certain things are

very improbable, and that others are probable, so that the investor is far better able to weigh the chances in his favor than if he merely stood at the bottom of the shaft and wondered what was below his feet. That, after all, is the basis of successful mining investment—careful weighing of possibilities, and judicious valuation of the 'mining chance' offered.

Prospective Growth in Output of Tin

The recent fluctuations in the price of tin caused considerable anxiety in the Malay Peninsula, as tin is the backbone of the country, and evoked much press comment on the subject. In this connection the following excerpt from an editorial appearing in the *Malayan Tin and Rubber Journal*, Ipoh, should be of interest:

"Mining methods are undergoing a gradual change in this part of the world by the introduction of the dredging system, which we believe is to have an effect upon the industry that at the moment is barely realized. We have gone carefully into the question and are led to the conviction that tin in the next two years will reach a level considerably lower than the average of the last two years. Nineteen dredges have been placed on various properties in Malaya and Siam. Dredges are to be laid down as follows: Malayan Tin, 4, probably 5; Chenderiang Valley, 1; Ipoh Tin Dredging, 1; Kampong Kamunting, 2; Kamunting, 1, probably 2; Larut, 1; Tekka Taiping, 2, probably 3; Pahang, 1, probably 2; Bruas, 1; Debook group, 1; Siamese Tin, 1, probably 2; Renong, 1; undesignated, 2. That gives a total of 19 certain, and an additional 19 likely to be laid down. The 'probables' actually number 24, for in addition to the Taiping and Siamese propositions mentioned, there is every chance of two other dredges being laid down in Taiping and three in Siam. All this in a way is a healthy sign * * * but it also means a greatly increased output, a conservative estimate of the monthly output of the average dredge being 400 piculs (26⅔ short tons). Now, above that we have to take into consideration the development in Nigeria, which, while not on the same scale as we are witnessing here, is still sufficient to make a good impression on the market. It is well known that some of the dredges are producing 600 piculs (40 short tons), and other methods are being pursued, including hydraulicking, lode mining, and calabashing. All that signifies a greater output. Bolivia, too, is reported to be showing excellent development work, and on the whole is systematically prosecuting the industry. The market, therefore, will not only have to bear an increased output from Malaya, but also from Nigeria and Bolivia."

Copies of a monograph issued by the Bureau of Foreign and Domestic Commerce as Special Agents Series No. 59, in which tin mining in the Federated Malay States is discussed at some length, may be obtained from the superintendent of documents, Washington.—*Daily Consular Report.*

Mineral Production of Virginia, 1913

By THOMAS L. WATSON

The statistics of mineral production in Virginia for the calendar year of 1913 were collected by the Virginia Geological Survey in coöperation with the Division of Mineral Resources of the U. S. Geological Survey. These statistics will be published later by the State Geological Survey in a bulletin which will review in detail the mining industry in the state for the year. The demand for the figures of production from all mines and quarries in Virginia in 1913 renders necessary their publication in abbreviated form in advance of the State Survey report. The latter, which will be ready shortly, will include figures for preceding years that will permit of full comparison.

Reference to the tabular statement below will indicate that the total number of productive operations for the year was large and included a variety of subjects; and that vastly the largest part of the total production is of non-metallic products. The returns indicate on the whole substantial gains in most of the products mined and quarried in the state. Some subjects showed very large increases, others remained nearly stationary, and others still showed decreases. The most noticeable increase was in coal and the most marked decrease was in iron ores.

While the iron ores showed a very marked decrease in 1913 over the previous year, the largest output of lead and zinc in the state for many years was indicated. The total value of gold, silver, copper, lead, and zinc in 1913 amounted to $386,244, an increase of $311,389 over the production of 1912. The total aggregate value of the mineral industry in 1913,* as shown in the table below, amounted to $19,144,997, as against $16,831,914 in 1912,* an increase of $2,313,083.

VALUE OF MINERAL PRODUCTION IN VIRGINIA DURING 1913

Product.	Value.
Clay products	$1,720,102
Coal	8,952,653
Coke	2,840,275
Iron ores	106,460
Lime	805,443
Manganese ores	40,480
Metals (gold, silver, copper, lead, and zinc)	386,244
Millstones	23,530
Mineral waters	298,473
Pyrite	587,041
Sand and gravel	239,591
Slate	175,830
Stone	1,063,782
Talc and soapstone	615,558
†Miscellaneous	1,289,535
Total	$19,144,997

†Includes barytes, cement (portland), gypsum, infusorial earth, manganiferous ore, metallic paint, mica, ochre, salt, and zinc oxide.

*Exclusive of briquettes (fuel), ferro-alloys, gems and precious stones, pig iron, and rutile.

The Menace of Mosquitoes and What to do About It

By THOMAS DARLINGTON

*To get rid of mosquitoes one must understand something of their life and habits. They breed only in still water, preferably dirty water. Some mosquitoes lay one egg at a time, while others lay as many as 300 eggs in the form of a raft. Such a raft measures one-eighth of an inch in length and can be seen with the naked eye. The eggs float on the water. Generally in about two days, depending mainly on the temperature, the eggs hatch and become the larvæ or 'wrigglers' so frequently seen in rain barrels. These 'wrigglers' breathe air through a small tube a little to one side of one extremity. If unable to obtain air at frequent intervals they die. In about a week the 'wriggler' changes into a comma-shaped creature called the pupa, from which in about two more days the mosquito emerges.

To exterminate mosquitoes they must be attacked in their breeding places. As mosquitoes breed only in water, it is necessary to remove or guard places where water collects. Tin cans, bottles, or any waste that may hold water should be removed. Tubs and barrels that are used to store water for household purposes should be covered. Roadside puddles, cup-like depressions in rocks, holes in tree trunks or stumps should be filled. Old ditches should be cleaned, gutters repaired, cisterns covered or oiled, water pans for chickens or other animals frequently emptied and cleaned. The edges of ponds should be kept free from grass. Marshes should be drained by ditching and the material from the ditches used to fill in the pools. Where it is impracticable to fill or drain, kerosene or crude petroleum should be used to cover the surface of the water. This will kill the 'wrigglers,' as the oil shuts off their air supply when they come to the surface to breathe. As fish feed upon the larvæ or 'wrigglers,' ponds should be stocked with fish. If necessary to secure action, legislation should be obtained to enforce the drainage of mosquito-breeding places. Mosquitoes in the house may be killed by burning sulphur, or, as with flies, pyrethrum powder, or a mixture of carbolic acid and camphor.

Fluorspar in Electric Smelting of Iron Ore

By ROBERT M. KEENEY

In connection with the general discussion of fluorite in smelting by Herbert Lang[1] in a recent number of this journal, some experiments that I have made show the effect of fluorspar in the electric smelting of iron ore to produce pig steel.

Fohs[2] states that the fluorine of fluorspar forms volatile fluorides with silicon, sulphur, and phosphorus of the charge, and that the calcium forms a silicate slag when fluorspar is used as a flux in the metallurgy of iron and steel, according to the following reactions:

$$2CaF_2 + SiO_2 = 2CaO + SiF_4$$
$$2CaO + 2SiO_2 = 2CaSiO_3, \text{ or}$$
$$2CaF_2 + 3SiO_2 = 2CaSiO_3 + SiF_4$$
$$3CaF_2 + 4S = 3CaS + SF_6$$
$$5CaF_2 + 7P = 5CaP + 2PF_5$$

As to the completeness with which these reactions actually occur, there is very little experimental evidence, and they appear to be based largely upon conjecture. But there is one indisputable fact regarding the effect of fluorspar: it thins a basic slag when used in small quantity, and on this, the assumption of its benefit was based in the following experiments.

Electric-furnace pig iron smelting differs from blast-furnace pig iron smelting in that the atmosphere of the electric furnace, while reducing, is less strongly so than that of the blast-furnace, because there is about three times as much carbon used for fuel in the blast-furnace as there is carbon for reducing material in the electric furnace. In the electric-furnace manufacture of pig iron, a slight excess of carbon is charged over that necessary for complete reduction. This results in the atmosphere of the furnace being completely reducing for all practical purposes and in the production of a pig iron. But there is not the great excess of carbon that is present in the blast-furnace. Sulphur is slagged as calcium sulphide as in the blast-furnace, with the possibility of slagging more of it owing to ability to operate the electric furnace with a very basic slag. Just as in the blast-furnace practically all of the phosphorus is concentrated in the metal in electric-furnace manufacture of pig iron.

When pig steel is produced from ore in the electric furnace, smelting conditions are somewhat different than when pig iron is the product. Carbon is charged in an amount sufficient to reduce the iron and carbonize the metal to the desired point. As pig steel is the product, which must contain less than 2.2% carbon to be a steel, no excess carbon can be charged over that theoretically necessary. Hence, while the atmosphere of the electric pig steel furnace is reducing, there is no excess carbon present, and conditions are much less reducing than in electric-furnace manufacture of pig iron.

The production of pig steel from ore in the electric furnace rather than making pig iron results in the following conditions: (1) There is greater loss of iron in the slag; (2) impurities are not so readily reduced to their metals which pass into the steel; (3) phosphorus is more easily forced into the slag; (4) it is more difficult to remove sulphur in the slag; (5) to produce a comparatively pure metal impurities of the charge must be slagged by use of a very basic slag; (6) to permit effective use of a basic slag for the removal of impurities, the slag must be fluid so as to allow intimate washing of the metal and charge by the slag.

Fluorspar was not used as a flux in these experiments in order to secure removal of silicon, sulphur, and phosphorus as volatile fluorides, but to thin the basic slag so as to permit absorption of these impurities as silicate, sulphide, or sulphate, and phosphate or phosphide. The work was performed in a furnace, lined with magnesite, having two upper vertical graphite electrodes connected in parallel, and a conducting hearth of iron rods imbedded in magnesite, the hearth and the graphite electrodes being connected in series.

Per cent iron slagged	4.92	5.73	4.08	4.70	4.36

The most marked result of the increased fluorspar charged in proportion to the lime is in the increase of carbon in the pig steel with each increase of fluorspar (Fig. 1). The amounts of ore and coke in the charge were kept constant in all of the experiments with the carbon at 27.4% of the iron in the charge. The lime was gradually reduced as the fluorspar was increased until the fluorspar was 18.5% of the lime charged as limestone. As the fluorspar increases the percentage of carbon in the steel increases from 0.44% carbon with

[1]Lang, H., 'Fluorite in Smelting,' *Mining and Scientific Press*, Vol. 108 (March 21, 1914), p. 492.

[2]Fohs, F. J., 'Kentucky Fluorspar and Its Value to the Iron and Steel Industries,' *Trans.* Amer. Inst. Min. Eng., Vol. 40 (1909), p. 261.

no fluorspar charged, to 2.25% carbon with 18.5% fluorspar. At this point the product was not a pig steel but was a pig iron.

The increase of carbon in the pig steel may be explained in two possible ways. The excessive thinning of the slag may have resulted in coke coming in closer contact with the steel, thus carbonizing it. Or, there may not have been any tendency to the formation of calcium carbide with the smaller percentage of lime in

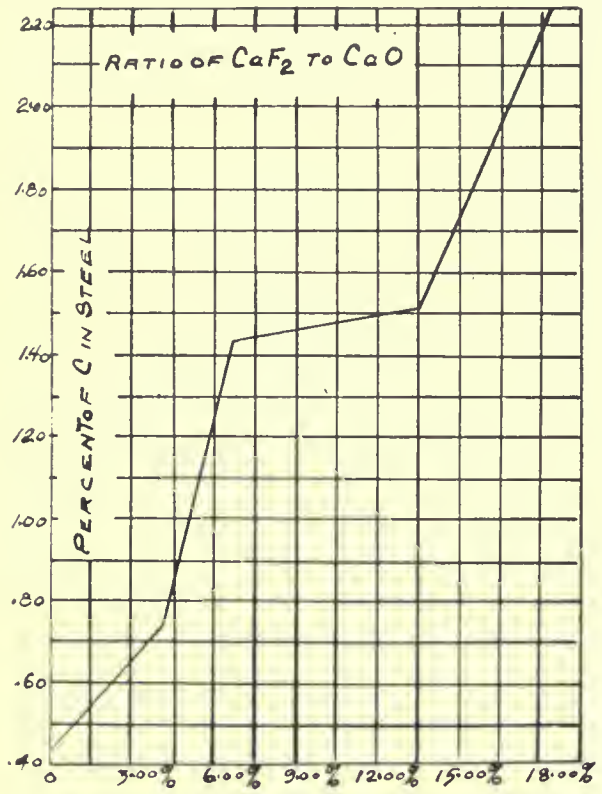

FIG. 1.

the charge, and the quicker fusion resulting from a more easily fused charge.

The effect of fluorspar upon the percentage of other constituents of the pig steel is shown in Fig. 2. There is a marked decrease in the percentage of silicon in the pig steel with increased fluorspar in the charge. The fluorspar has no apparent effect on the manganese. The percentages of phosphorus and sulphur in the pig steel decrease with a small amount of fluorspar, but the phosphorus increases in the steel with the ratio of fluorspar to lime above 13.5% and the sulphur with the ratio over 4.5%. In the opinion of the writer the elimination of silicon, phosphorus, and sulphur from the metal, is due largely to the thinning effect of the fluorspar upon the slag which permits intimate contact and washing of the metal by the slag. Silicon, phosphorus, and sulphur in this way have a greater opportunity of combining with lime to form silicates, phosphates or phosphides, and sulphates or sulphides. Either of the latter might form owing to the weakly reducing atmosphere of the furnace. The value of a very thin fluid slag for the removal of phosphorus in the reduction of iron ores and in the manufacture of ferro-alloys has been evident throughout the experiments I have made, and it was to get this thinning effect that fluorspar was tried in these experiments. The increase of impurities in the pig steel when the fluorspar is used in large excess is due probably to a reduction of these impurities after they have once been slagged, because of the thinness of the slag and the evident presence of excess carbon as shown by the increased percentage of carbon in the steel.

In summary, it may be stated that:

1. In the electric smelting of iron ore or the manufacture of ferro-alloys a small quantity of fluorspar in the charge assists materially in the production of a fluid basic slag for the absorption of impurities.

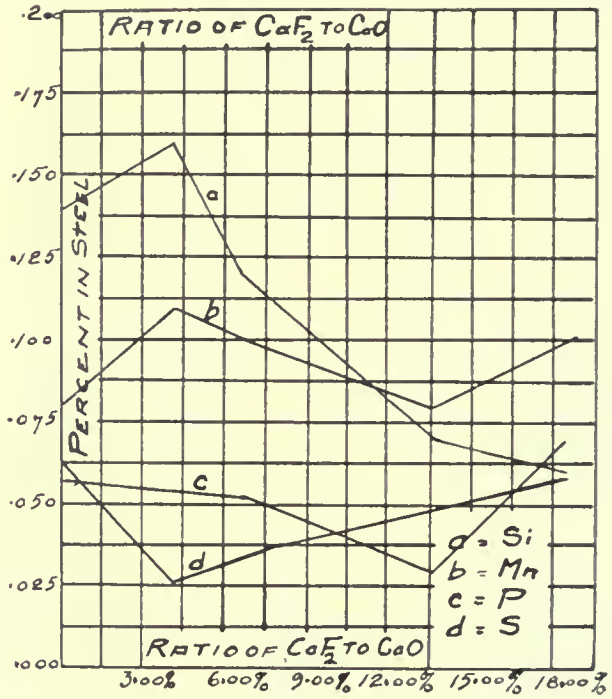

FIG. 2.

2. The use of fluorspar in excessive quantities causes a marked increase in the carburization of the pig steel.

3. The addition of fluorspar lowers the percentage of silicon in metal.

4. If a small amount of fluorspar is added to thin the basic slag, slagging of phosphorus and sulphur is assisted.

5. Fluorspar has no apparent effect on loss of iron in the slag, nor does it appear to affect the power consumption, although the experiments were on too small a scale to give definite figures regarding the latter.

GOLD PRODUCTION of some Rhodesian mines in June was as follows:

Mine.	Tons.	Yield.	Profit.
Cam & Motor	10,409	£15,204	.....
Giant	7,658	4,414	£ 805
Globe & Phoenix	6,117	41,820	27,000
Lonely Reef	5,750	16,815	8,715
Pigg's Peak	3,063	3,710	946

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply to F. H. Hatch's Discussion—*Continued*

With reference to Mr. Hatch's statement that no suggestion was offered as to how such a replacement might have taken place, I showed that it had already been accepted, that very similar replacement had actually taken place in the Rand banket at the Meyer & Carlton mine. It was unnecessary to enter into the chemical questions of how this had occurred as, to students of ore deposits, it was already well known that pyrite could metasomatically replace quartz and often had done so. Petrologists had also been forced to recognize that quartz could be metasomatically replaced by pyrite. As long ago as 1877, Naumann[7] had recognized this. Mr. Lindgren in 1900 had also clearly shown that this process was quite a common one in ordinary vein formation.[8] I quoted the analogy of the pyrite replacements in the English chalk, and did so again in my paper on the Rand banket, where I pointed out that many of the pyrite nodules occurring in the chalk in the upper Cretaceous formation of England had been formed, or partly so, by the replacement of silica of sponge spicules.

Because some of the pyrite pebbles exhibited radiate structure, Mr. Hatch apparently thought that the mere statement of his personal opinion that they were of concretionary origin was sufficient explanation of their presence. In my paper on the Crown Reef occurrence I pointed out that the pyrite pebbles do not all exhibit radiate structure, and that those which do might be concretions, or quite possibly pseudomorphs, as this structure may have been developed later owing to gradual molecular rearrangement. Later, in my treatise on the Rand banket, I pointed out that to state an opinion that the pyrite pebbles owe their shape to growth by accretion, or that they are concretions, proves nothing and merely leaves the problem where it was before. I then showed that this radiate structure is a later development, doubtless due to contraction.

Mr. Hatch in criticizing my present paper stated that after the publication of the first edition of the 'Geology of South Africa,' written by G. S. Corstorphine and himself in 1905, they came across pyrite pebbles that showed no concentric or radiate structure and were curiously flattened or of ellipsoidal shapes; they admitted that these certainly recalled the appearance of true pebbles, and that the possibility of these being pseudomorphs after quartz pebbles suggested itself, but remained a mere supposition until proved by the careful microscope work of R. B. Young, which was embodied in a paper read before the Geological Society of South Africa, on March 18, 1907.

Curiously enough, Prof. R. B. Young, working in the laboratory, and I, in my daily underground work in the mines, had quite independently, and each in ignorance of the other's work, arrived at the same conclusions. It amounts to little that mine were embodied in a paper completed in the latter part of 1906, received by the Geological Society of London in January 1907, and read before that society on February 27, 1907, and that his were read somewhat later, on March 18, 1907, in Johannesburg. In my paper 'The Rand Banket' I think I have made full acknowledgment to Professor Young for his valuable work. Mr. Hatch says that the discussion was again dealt with in Mr. Gregory's paper on 'The Origin of the Gold in the Rand Banket,' read before the Institution of Mining and Metallurgy in October 1907, and that Mr. Gregory, while appearing to think that these pyrite pebbles are water worn, does not deny the possibility of their pseudomorphous origin. Mr. Hatch then proceeds to still further labor the burden of his theme by stating "that the idea of the pseudomorphous origin of the pyrite was in the air, prior to the reading of Mr. Horwood's paper, is further shown by the fact that Mr. Gregory also suggested it in a lecture at the Society of Arts which was given on February 4, 1907." Mr. Hatch omits to mention that Mr. Gregory was sufficiently generous to give me, in his paper, full credit for having contended that some of the pyrite pebbles from the Crown Reef mine are pseudomorphs after quartz pebbles.

Reply to Mr. Hatch's Second Discussion

In the latter part of my paper, when considering the genesis of the pyrite and gold in the Rand bankets, I stated that it cannot be too strongly borne in mind that the latter differed in no important *essentials* from ordinary gold quartz veins. The solutions had found these pebble beds sufficiently pervious to select them rather than fissures for circulation and precipitation of their mineral contents; and these channels finally became closed to further mineralization by deposition of secondary silica, which, I pointed out, is analogous to

[7] See 'Elemente der Mineralogie,' by C. F. Naumann, Leipzig, 1877, p. 115.

[8] 'Metasomatic Processes in Fissure Veins,' by W. Lindgren, in 'The Genesis of Ore Deposits,' 2nd Ed., 1902, p. 502.

the vein quartz of ordinary lodes; and that in a similar way quartz veins had eventually been sealed by the deposition of vein quartz and other gangue material. I also pointed out that as long ago as 1890 J. S. Curtis realized that the gold and pyrite of the bankets was genetically associated with intrusions of basic dikes; and when he first visited the Rand in company with Gardner F. Williams, in 1887, the latter maintained that the gold was quartz gold deposited late in the history of the banket. Mr. Curtis, in 1890, as a result of his investigations, concluded that in many of their characteristics the bankets closely resembled lodes; and in 1908 he contended that if the theory of infiltration is accepted as accounting for the presence of gold in quartz veins, there seemed no valid reason why the presence of gold in the banket should not be accounted for in a similar manner.

I maintained that had the analogy not been masked by the fact that the lodes are composed of ordinary sedimentary conglomerates which have been considerably metamorphosed, the similarity would long ago have been recognized and their mineralization ascribed to the influence of the older, or longitudinal, series of dikes, or to the magma with which in depth the latter are connected. These dikes furnish abundant and *sufficient* evidence of former deep seated communications whereby the mineralizers ascended. I referred to various previous publications by myself, between the years 1905 and 1912 inclusive, in which I had laid special emphasis on these points. Thus, in 1905, I called attention to the genetic relationship between the dikes and the Ventersdorp diabase and the influence of the former on the mineralization of the bankets.[1] Again in 1910 I wrote as follows:[2] "Accepting the infiltration theory of the origin of gold in the bankets, the latter may be looked upon as differing in no important essentials from ordinary veins. In this connection the words of J. F. Kemp, in his paper 'Igneous Rocks and Circulating Waters as Factors in Ore Deposition', may be quoted. Having advanced several arguments in support of the importance of these factors, especially of the former, in ore deposition, he goes on to state: 'If, now, we add to the above considerations the further one of the almost constant association of eruptive rocks with veins and the usually very restricted occurrence of the latter, it seems to me that, areally considered, we have adequate reason to attribute to the former, and especially when there is no positive contradictory evidence, very great importance in vein production.' Dike intrusions are largely responsible for the faulting and fracturing met with in the mines of the Rand. Thus, if the infiltration theory be the correct one, we have here a sufficient explanation of how deep seated communications were produced, through which mineralizing solutions could have ascended; and possibly future work may show that the Rand owes a very great debt to that period of eruptive activity to which the Ventersdorp series is due." I again emphasized these conclusions in the later papers to which I made reference; and stated that the unprofitable banket veins are analogous to the barren quartz veins which so frequently occur in the neighborhood of gold-bearing quartz veins. In my treatise on 'The Rand Banket' I mentioned that since, in the papers quoted, I had emphasized the similarity of the bankets to ordinary gold quartz veins and had laid stress on the importance of the dikes in the general scheme of mineralization of the banket, others had gradually adopted the same view, and gave as an example that Mr. Hatch wrote in 1911, with reference to the Rand banket, that evidence was slowly accumulating to prove that its gold content has an origin similar to that of quartz veins.

Mr. Hatch now maintains that he had long previously held these views. As lending a curious color to his criticisms on my paper, I would mention that in this same brief article of his,[3] to which I referred, he made the following statement: "Another authigenic constituent which, though rarely absent, is only relatively abundant in a few mines, is a graphitic variety of carbon. C. R. Young has recently recorded observations which are opposed to the view that this carbon has been derived from original organic matter deposited during sedimentation; since, according to him, it has in some places replaced the carbon of the banket, thus suggesting that it has been introduced at a late period in the history of the rock, by the vehicle of the magmatic vapors accompanying the intrusion of the abundant igneous dikes." Against Young's name one is referred to a footnote, and it, together with footnote 14, are the only footnote references to papers where the name of the author is not given in the footnote itself. This footnote reads as follows: "*Trans.* Geol. Soc. So. Af., Vol. 13, 1911, p. 65." On looking up this reference it will be found to be to a paper entitled 'The Mode of Occurrence and Genesis of the Carbon in the Rand Banket,' written by myself.[4] As a result of considerable research work and numerous analyses, I showed in this paper that the carbon was not derived from original organic matter deposited during sedimentation, and that its occurrence in the banket is closely associated with that of the pyrite and gold and indicates a close relationship between its presence and that of neighboring basic dikes, which I proved contained carbon. I pointed out that the way it occurs in tiny spheroids scattered through the matrix, sometimes occurring in the body of quartz pebbles where no cracks are to be seen, and sometimes embayed into their edges, could

[3] 'The Conglomerates of the Witwatersrand,' in 'Types of Ore Deposits,' 1911.

[4] Footnote 14 refers to the same paper, and the author's name is not given. [The reviewer is apparently in error here, as footnote 14 is as follows: "A. Crosse, *Trans.* Geol. Soc. S. A., Vol. XIII, 1910, p. 77." See page 214, 'Types of Ore Deposits.'—EDITOR.]

only be explained as a result of deposition from gaseous or very mobile liquid hydrocarbons in a similar manner to that of the carbon mineral at the Mary mine, as described by Mr. Kemp, before the final cementation and induration of the bankets by the deposition of secondary silica; and I attributed its origin to magmatic vapors or solutions derived from the neighboring basic intrusions before their final solidification. Professor Young also observed instances of the carbon occurring in the pebbles, and concluded that in such cases it had replaced quartz, and in discussing my paper[5] admitted that I had demonstrated the interesting fact that carbon occurs in dikes associated with the banket; but, far from him suggesting that it had been introduced by the vehicle of the magmatic vapors accompanying the intrusion of the abundant igneous dikes, he was so loath to admit that the dikes were the source of the carbon that he asked, supposing that it has a source other than the dikes, what there was to hinder the substance from which it was precipitated from permeating the dikes just as it had the sedimentary rocks.[6]

Mr. Hatch takes exception to my statement that since I have on several occasions emphasized the similarity of the bankets to ordinary lodes he, among others, gradually adopted the same view. He quotes from a paper read by him in 1897 in which he said: "The silicification, or more generally the mineralization, of these conglomerates is, in my opinion, the result of secondary processes of infiltration and crystallization. It is significant in this connection that when most mineralized the conglomerates are often seamed with veins of white quartz, and there can be little doubt that these veins were formed in connection with the mineralization of the conglomerates. There is no reason for ascribing a special method of origin to the gold; and I hold, therefore, that the gold has been introduced with the pyrite with which it is in intimate association, as a part of the general process of mineralization, and I cannot agree with those authors who describe the conglomerates as deposits in which the gold was either pre-existing (alluvial gold) or was introduced contemporaneously with the deposition of the pebbles and sand." From this statement he clearly holds the infiltration theory, and in my paper I have given him every credit as a supporter of this theory. Unfortunately, although he maintained that the gold had been introduced with the pyrite as a part of the general process of mineralization and called attention to the significance of the presence of veins of quartz and thought there was no reason for ascribing a special method of origin for the gold, yet he did not state what he considered the general processes of mineralization were. Such a non-committal statement is a very different thing to his much more definite statement in 1911 to which I made reference. The former is ambiguous, awaiting the outcome of what future work might reveal; the latter is more definite as the result of the meanwhile labors of others. Mr. Hatch now seems to suggest that as long ago as 1897 he considered the bankets analogous to quartz lodes. If so, he has had very numerous opportunities of definitely stating his opinion, in clear and unmistakable terms, notably during the discussion on Mr. Gregory's paper, written in 1907, on 'The Origin of the Gold in the Rand Banket.' Why did he not do so?

[6] I dealt with Prof. R. B. Young's query in my paper on the Rand banket.

The Normal-Federal Suit

The Editor:

Sir—Will you allow me to offer a few words of explanation regarding the opinion of Mr. Justin Philbin, of the New York County Supreme Court, in the suit of myself and other minority stockholders of the Federal Mining & Smelting Co. against the American Smelting & Refining Co., which was published in part in your issue of August 8?

While the actual plaintiffs mentioned in the suit only owned 2% of the capital stock of the Company, my attorneys actually represented 130 stockholders with par holdings of approximately $750,000. They did not believe that a question of law could be decided by force of numbers, so that the additional plaintiffs were not added in the amended complaint. Three other stockholders, owning an aggregate of close to $1,000,000 worth of stock at par, complained in writing to the officials of the American Smelting & Refining Co., pointing out the unjust features of the contract and asking that it be revised to the same level as other contracts then in existence with other producers in the same district which were not controlled by the smelting company.

This was a representative form of action and it is therefore apparent that all stockholders would participate in any success that might attend our efforts, whether they contributed to the expense of the suit or not. It is this fact that accounts for the comparatively small amount of protesting stock, together with the further important fact that stockholders had lost such tremendous sums in decline of securities that many were absolutely unable to help in the fight. As a matter of fact, the present contract is strongly condemned by every minority stockholder who has any knowledge of the methods adopted to deprive them of a just return for the Company's ores.

The Circuit Court of Appeals will be asked to review the entire case, arrangements for appeal being now under way. I do not confess to be versed in the law, but I do believe that the higher court will rule that the amount of protesting stock has nothing to do with the questions of law involved in the action. If such a decision should stand, it is very evident that minority stockholders would have no chance to correct wrongs forced upon them by an unscrupulous majority.

SIDNEY NORMAN.

New York City, August 13.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE OTIRA TUNNEL through a portion of the Southern Alps of the South Island of New Zealand is now in over two miles of the total of 5.3 miles. The grade is 1 in 33.

SILVER CAPACITY of bullion molds in troy ounces may be calculated by multiplying the cubical contents, in inches, by 5.57. Fine gold capacity may be calculated in the same way, by multiplying the number of cubic inches contained by 10.1.

SUPERHEATED COMPRESSED AIR is the latest addition to the proposed remedies for cancer, others being surgical operations, radium emanations, and charges of high-frequency electric current. The air has an impinging or penetrating effect which it is hoped will be beneficial.

STEAM generated from waste heat of eight reverberatory furnaces at the Washoe plant, Montana, produces 30% of the 16,700 mechanical horse-power used in the entire concentrating and smelting plant. About 25% of the heating value of the total coal is made effective, while only 15% of this value is actually used for smelting.

RECOVERY OF ZINC from ores by ordinary wet concentration at several mines is as follows: Daly West, Park City, Utah, 50% zinc, 95% lead, and 75 to 80% silver; Daly-Judge, same district, 66% zinc, 92% lead, and 78% silver; Buffalo Hump, Burke, Idaho, 25% zinc, 90% lead, and 85% silver; and Joplin district, Missouri, 65.43% zinc. By flotation processes the zinc recovery may be increased to from 66 to 91 per cent.

ORE BROKEN per miner and shoveler per shift at the Mt. Morgan mine, Queensland, is 2.47 tons per 8-hour shift. The cost per ton of ore for underground employees and explosives is $1.14. Average earnings of miners on contract (stoping) is $3.84, and on development, $4.64 per shift. Horse traction of ore, from stope chutes to the main shaft underground bins, in place of electric locomotives, has expedited and cheapened haulage.

RUN-OFF from the watershed of Gatun lake, Canal Zone, during the dry season, January to April inclusive, was 16,953,000,000 cu. ft. This is 61% of the normal dry season run-off as determined by the average of 25 years of record. The lake was maintained at approximately normal elevation, 85 ft., throughout the season. The wastage of water through the spillway for lockages, and Miraflores lake was 4,854,000,000, 256,000,000, and 581,000,000 cu. ft. respectively.

MATTE found on the top of bars of cyanide bullion usually assays high in silver, even though the bullion itself contains but a relatively small proportion of the white metal. It has been stated that the matte contains, and oftentimes is principally composed of, a sulphide of silver. Apparently the sulphur has a greater affinity for silver than it has for gold, for bullion carrying 800 parts of gold and 100 of silver has yielded matte assaying 100 oz. gold and 5000 oz. silver per ton.

A MODEL PACHUCA VAT is a necessary apparatus in a metallurgical laboratory. It can be constructed with flat galvanized iron, afterward coated with paraffin paint. The diameter of the lift-tube should be about one-tenth the width of the tank, and arrangements should be made so that the air pressure necessary to operate the lift is at a minimum, otherwise excessive evaporation will take place. The quantity of air used should be arranged so that the pulp is in efficient agitation, and there is no settlement and accumulation of solids in the cone at the bottom of the vat. Particular care should be taken in this respect, otherwise very misleading results may accrue, due to an exclusion of richer and heavier portions of the pulp from any sample that is taken at the lift discharge. In such a model apparatus the pulp is in more vigorous agitation than it would be in a full-sized vat, and allowance must be made for this fact in any estimation of tank capacity required in practice which has been based on the results of such experimental work.

BASIC-LINED CONVERTERS have been used at the Old Dominion smelter at Globe, Arizona, since the first month of 1913. One has recently completed a year's run without repair. According to L. O. Howard, in the July *Bulletin* of the A. I. M. E., the record of a 12-ft. shell, provided with 24 1¼-in. tuyeres, and a mouth 5 ft. in diameter, was as follows over the period of January 6 to June 27, 1913: Total blowing time, 2689.66 hours; number of blows made, 664; average time of blow, 4.05 hours; matte charged, 18,157 tons; average content of matte, 43.9% copper; time blowing one ton of copper, 22.5 minutes; copper produced, 7250 tons; copper per converter hour, 2.66 tons; air used per minute, 9000 cu. ft.; blast pressure, 13.3 lb.; and ore fed, 3304 tons. The slag averaged 2.5% copper. A mistake was made on first working the converter in blowing large charges, which resulted in trouble. This converter, due to certain arrangements in the smelter, was often crowded to its utmost capacity by frequent fluctuations in the daily matte supply.

MINING IN THE FAR NORTH*

Seward and the Kenai Peninsula

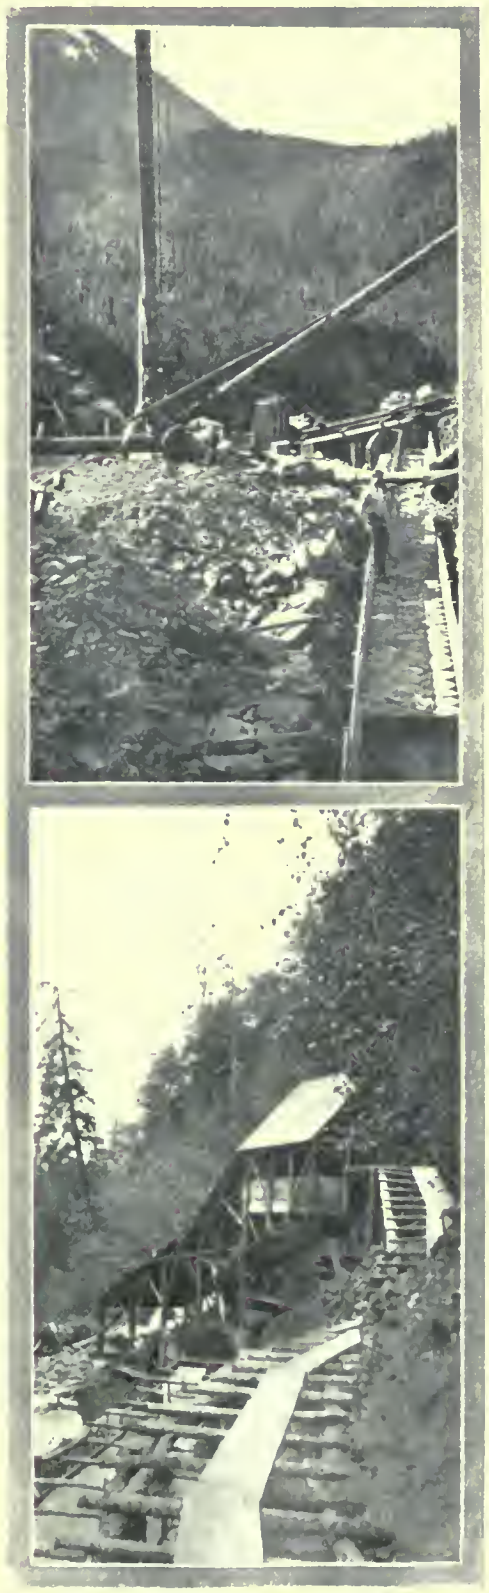
By E. E. HURJA

Kenai peninsula, in southwestern Alaska, has an area of 9000 square miles. It has been the scene of gold mining for many years. Recent work has been devoted to quartz prospecting, with the result that many promising properties are being developed. Gold was first discovered in Alaska in 1848 in streams tributary to Kenai river, by P. P. Doroschin, an engineer making an examination of the mineral resources for the Russian-American company. No work is known to have been undertaken at that time. Gold was discovered on Cooper creek in 1884, on Resurrection creek four years later, and at Anchor Point in 1889. It was not until 1896, however, that any great amount of attention was given the district, and then several thousand men stampeded into the new field. In 1898 another stampede to the Turnagain Arm district took place, and since that time placer mining has been carried on along most of the creeks of the district. Hydraulicking and dredging are superseding the old pick and shovel methods. Gold-bearing lodes were given attention as soon as the richest placer ground was taken out. John C. Gilpatrick found float in the Moose Pass district in 1896, but did not locate the vein until 1906.

The townsite of Seward was located in 1902, when the Alaska Northern railway started to build to the interior. The camp was lively and grew rapidly until 1906, when President Roosevelt's executive order withdrawing the coal lands from entry put a stop to the railroad. Since that time, until the present railroad activity, the town has been the supply centre for the peninsula and an outfitting point for cannerymen, hunters, and a few stray prospectors. It has a population of about 800. Government engineers are surveying along the route of the Alaska Northern railway, which runs 71 miles from Seward. No less than ten different parties are at work in the Seward and Cook's Inlet country. Toward the interior from Cook's inlet many prospectors have sought mineral for years. Promising prospects have been found, but nothing extensive in the way of development has ever been done. The recent resumption of surveying for a railroad into the back country has attracted attention anew to the possibilities of the region, and numerous parties of engineers and prospectors have gone in to look for mining properties. The productive activity in the Seward district at present is confined to the hydraulic plants near Sunrise and Hope, as well as the northern side of Turnagain arm. Some quartz mining is being done in the Willow Creek country and in the district between Seward and the present terminus of the Alaska Northern railroad at Mile 71.

The Telkeli district, northeast from Seward, on the north side of the Chugach range, is demanding attention. Fred Reist, 2½ miles south of Telkeli, has a lode varying in width from one and one-half to four feet, on which he is extending an adit already driven on the lode 100 ft. E. L. Dickey and associates are preparing to develop the Portland group of claims. Five tons of supplies are on the ground. Red Ellis and Nick Mickum are driving an adit on their property.

Only assessment work is being done for the present on the Seward Bonanza Gold Mines Co.'s property, situated on the mountain between Victor and Ptarmigan creeks. The vein was discovered in 1907, and development started four years later. An adit has been driven about 200 ft. on the lower vein, with an average width of 2½ ft. Surface work has been done on the upper vein. Pending a settlement of financial difficulties, the property of the California-Alaska Mining Co. is idle. It is situated at the head of the cañon on Falls creek. It was discovered by F. P. Skeen and John Lechner in 1905. It shows much promise and a 2-ft. vein has been opened with 180 ft.



SLUICE-BOXES, STEWART BROS. MINE

BLUE BELL MILL.

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangle, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15. Mr. Hurja is now in the interior, and in subsequent letters will give our readers full accounts of present conditions in each of the great producing districts of the Far North.—EDITOR.]

of drift and a 40-ft. winze. A two-stamp Hendy mill and concentrator have been installed. The milling plant was the first on Kenai peninsula. It consists of a Ford crusher, an automatic feeder, and a Deister No. 2 concentrator. Power is furnished by a Pelton water-wheel operating under an 80-ft. head.

The mill on the Kenai-Alaska Gold Co.'s property on the north side of Falls creek will be in operation again by August 1, according to James R. Hayden, the manager. Water entered the workings early in July and put a stop to all mining. Plans for unwatering the mine are now under way.

COALFIELDS OF ALASKA, ACCORDING TO THE U. S. GEOLOGICAL SURVEY.

Pumping equipment will be installed. The Company owns five claims about 26 miles from Seward and five miles from Kenai lake. Underground work aggregates 1600 ft. in adits, raises, and drifts. The lode varies in width from a few inches to 2½ ft. The ore averages $50 per ton. The milling equipment consists of a Blake crusher for the oversize of a 1½-in. grizzly, a five-stamp Risdon mill with 1200-lb. stamps, amalgamating plates, and a Risdon-Johnston concentrator. Concentrate is shipped to the Tacoma smelter. A ½-mile Bleichert aerial tram connects the mine workings with the mill, which is at timber-line. Fuel is wood, costing $5 per cord delivered.

Reports are that the mill on the Skeen-Lechner property will resume operations within another month. The claims are on the north side of Falls creek and were located by F. P. Skeen and L. F. Shaw in 1907. Two adits on the claims, with an aggregate length of 1200 ft., have opened two veins 100 ft. apart to a depth of 155 and 300 ft. Each of the veins varies in width from 2 to 20 ft. and contains gold at the rate of $10 to $13 per ton. A Lane mill has been installed and is connected with the mine by a 2800-ft. aerial tram. Harry Johnson is prospecting a claim on Lechner peak, north of Ptarmigan lake. The adit on the lode has a length of 200 feet.

On Porcupine creek, 18 miles north of Seward, the Primrose mine is being developed under John F. Rea. The mine, made up of three claims, is owned by Derick Lane. A 6-ft. lode has been opened with 400 ft. of underground work. The milling equipment comprises a Little Giant mill. Depth on ore of 435 ft. has been attained. Plans for further development are under way. A crew of men is employed on the Case-Whitney property, at Grant lake, held by James R. Hayden under bond and lease. Three tons of selected ore was shipped to Falkenburg & Laucks at Seattle, from the three parallel veins last fall, and yielded $234 per ton. The veins are from 18 in. to 2 ft. in width. Two of the veins are 15 ft. apart; the third is 500 ft. distant. Present work is being done on the first two veins. The Skeen-Johnson property, opposite Mile 34 on the south side of Grant lake, is being opened up steadily. The two claims Sourdough and Checbaco are about to be bonded to an Eastern mining man. An arrastre is operating on the Moose pass property of John Gilpatrick. A mineralized porphyry dike 8 ft. in width, assaying $4 per ton, with from 12 to 14 in. of rose quartz stringers even richer, is being developed from adits now totaling 500 ft. in length. The claims are at an altitude of 3500 ft. The property has been sampled by engineers of the United States M. S. & E. Co., an English corporation. A mill test of one ton of picked ore, recently taken out by pack-horses, yielded $100. J. W. Slater is operating an arrastre in connection with his prospecting work on Colorado creek. Robinson & Calwell are prospecting on Pass creek. On Summit creek, below the Gilpatrick claim, Imhoff & Saulisberry are planning to erect a stamp-mill as soon as their present prospecting has demonstrated the value of their ground.

In the Willow Creek district, the Gold Bullion property is operated steadily. Budd and associates have the claims in charge under an option and lease. A seven-stamp mill has been installed and is connected with the mine by a 3400-ft. aerial tramway. Thirty men are employed. The 1913 production was $56,000. With the addition of a small cyanide plant with which to treat the tailing, it is expected that the 1914 production will be about $100,000. William Martin has a lease on the Free Gold property on Fishhook creek. Two veins are being worked. A Lane mill is in operation and another is being installed. Twenty-five men are employed. The 1913 output was $50,000, and the first clean-up this year brought $17,000. A 3000-ft. aerial tram connects the mine with the mill. The lode is 10 ft. wide. The Independence property adjoining has been taken over by a company of which T. W. Hawkins, of Seward, is president. L. S. Robe is engineer in charge. A prospecting plant, consisting of one Nissen stamp and two Hendy stamps, is operated. The ore is yielding from $40 to $50 per ton. Adit work totals 450 ft. A Lane mill will be installed this fall, which Mr. Robe expects will increase the capacity threefold.

A five-stamp Hendy mill is in course of construction on the Rosenthal property. Three hundred fifty feet of adit has been driven on a vein from 3 in. to 2½ ft. wide. Skeen, Babcock, and McCoy are open-cutting on their lode on Reed creek. Three thousand five hundred feet of surface work has been done on a vein varying in width from 2½ to 7 ft. William Bartholf is prospecting on Archangel creek. J. W. Hamilton and H. E. Ellsworth have taken a lease and bond for $32,000 on a group of claims near Mile 4 on the Alaska Northern railway. An adit was started to cut the lode, but after being run a distance of 195 ft., was abandoned. Two small levels have been started, one at a depth of 40 and the other of 60 ft. from the surface. A shipment of ore of 15 tons taken between the two levels yielded $31.80 per ton after freighting and smelting charges had been paid. Late in

July a cross-cut will be started on the Big Redmond property, situated on Resurrection river, 13 miles from Seward. The group comprises nine claims, on which a proposed 150-ft. adit has been driven 40 ft. The lode is from 2 to 8 ft. in width. J. P. Stotko is the chief owner. F. P. Skeen and Harry Johnson found a lode on July 9 at the head of Afanasi creek, tributary of Resurrection river, after a discovery of float dug up by a bear hunting a ground-hog. The Lucky Jean and Bearhole claims were located. Samples of ore from the 2½-ft. vein gave assays of $50 per ton. Development has been started. Henry Culliard is building a trail to his claims on Devil creek. He is preparing to run an adit on his lode, which has a width of 2 feet.

Placer gold has been found on nearly every stream of the mountainous region of northern and central Kenai peninsula. In few places, however, have the gravels carried sufficient gold to permit mining. Hydraulicking and dredging are the only methods of profitable mining now employed, and the single dredge of the district has been abandoned because of engineering difficulties. Tallaine & Nelson are operating a

SEWARD AND ITS HARBOR.

No. 2 giant on Canyon creek. Joe Wilson, Jr., is operating on the same stream with one nozzle. On Placer river John Dubreuil has 10 claims on which he has done considerable prospecting. The depth to bedrock is 14 ft. Two years ago he shoveled in gravel in the cañon at the rate of $1 per hour. On Gulch creek, Adolph Young is installing hydraulic equipment with the intention of starting work this fall. On Mills creek Robert Michaelson is working on a small scale. Jack Renner is engaged on the same stream with a small outfit. The entire stretch of Kenai river where prospects have been found has been bonded by J. R. Hayden. T. Mack, an engineer in the employ of the Guggenheims, is making an examination. Keystone drills are to be used in prospecting. The ground is looked upon as favorable for dredging purposes. Gold was first discovered on Kenai river in 1910, and the next year the Kenai Dredging Co. erected a small dredge. It did not save the gold anticipated, and another larger one of the same type was built. Both are idle.

The Kenai Mining & Milling Co. is operating five giants on Cooper creek. Its holdings take in all the ground from Cooper lake to Kenai river. A Ruble elevator is in use. Water for hydraulicking is obtained from Stetson, Wildhorse, and Kickinghorse creeks by 5¾ miles of ditch and 1300 ft. of flume.

The Fairman claims on Quartz creek, tributary to Kenai lake from the north, have been bonded to Herschell Parker, of New York, who is reported to have a crew of men engaged in prospecting the holdings with a view to dredging.

The Conant property on Sixmile creek has been taken under option by Herron & French. A small crew of men are making an examination of the claims. Resurrection creek is the westernmost producing stream which flows into Turnagain arm and was worked earlier than any other stream in the district. The Mathison Mining Co. has three nozzles at work and is reported to be making $200 per day above expenses of operation. Water is obtained by ditches from Bedrock and Rimrock creeks and 3000 ft. of pipe-line. Two No. 2 Hendy giants and one No. 1 giant are operated under 315-ft. heads. The Carstens Mining Co. operates one giant below the Mathison workings. Collins, Allison & Farrand, operating above Mathison, make use of two giants to carry the gravel into boxes and one to stack the tailing. Gust Seiffert is working 30 men on Resurrection creek. Buildings have been erected, 1500 ft. of ditch has been built, and a pipe-line is being installed. Within ten days, the plant will be ready for operation.

The first clean-up of the season on Crow creek was made July 14. For a four days' run, $12,000 was obtained. The only plant working on Crow creek, which is the only producing stream flowing into Turnagain arm from the north, is known as the Nutter & Dawson outfit, owned by the Alaska Crow Creek Mining Co., of which H. L. Jaffe, M. B. Sollner, and R. B. Dawson are the principal owners. Twenty-seven men are employed, and as soon as a night shift is put on, within the next week, 15 more will be added. Present operations are being carried on three-quarters of a mile above the head of the rock cañon in Crow creek. Two giants, one No. 7 and another No. 9, are operated, and 4000 yd. of dirt is moved per day. One No. 4 giant is used to stack tailing. Three thousand inches of water is obtained with a ditch 1½ miles, and a pipe-line over 3000 ft. in length. The head varies from 300 to 350 ft. Gold-saving apparatus consists of 1100 ft. of sluice-boxes with 12-in. hemlock block riffles. For the first 100 ft. the blocks are covered with pieces of railroad iron placed crosswise at intervals of one foot, in order to protect the blocks from excessive wear from boulders. Where the boxes follow the bends in the creek, a ¼-in. sheet steel lining is used. The owners expended $200,000 in sluicing a channel 1800 ft. long and 225 ft. deep in order to reach the 'pay.' It is estimated that 8,000,000 yd. of gravel was moved, with a recovery of gold of $60,000. Plans for a dam 35 ft. in height, near the head of Crow creek, are being made, as part of a power project. The Girdwood company has holdings farther upstream, but is unable to work them because of lack of room for tailing.

A Keystone drilling outfit has been sent to Raspberry island to prospect placer ground. On Unga island, Frank Brown is installing a cyanide plant four miles from the town of Unga which will be used to work the tailing of the old Alaska Commercial company enterprise, the Apollo mine. The plant will have a capacity of 200 tons per day, and there are 800,000 tons of tailing to be worked. The Apollo mine is credited with producing over $4,000,000 with a 100-stamp mill in operation for years. Only a few stamps are being operated now. Beach placer mining is being conducted on Kodiak island, Uganik bay, Uyak bay, Red river, Alitak bay, and Tagidak island.

Pyrrhotite deposits are reported from Iron creek, in the Chulitna. The Wells brothers have uncovered a deposit of arsenical iron on Honolulu creek. George Perkins is developing a copper prospect on Indian creek. Finch and Campbell have gone toward Broad pass along the proposed railway route with a view to investigating mining properties.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ANGELS, CALIFORNIA

HOME-COMING WELCOME TO A RETURNED CALIFORNIAN.—OLD NEIGHBORS AND FRIENDS WELCOME W. J. LORING.—MR. LORING TELLS OF THE PLYMOUTH AND THE POLICY OF BEWICK, MOREING & COMPANY.

Nearly 100 of the leading citizens of Calaveras county and operators along the Mother Lode gathered together at Calaveras Hotel, Angels Camp, on the evening of August 20 to extend a California welcome home to W. J. Loring, and to tender to him a banquet. While Mr. Loring was born in San Mateo county, he began his mining career in Amador and was millman at the Utica from 1888 to 1901. He went from there to become manager at the Melones and from there to Western Australia in 1902. From that state his activities have extended to all parts of the world, and his old neighbors and friends have watched with great interest his various successes. The recent completion of the Plymouth mill and the reopening of that famous old mine through his activities, were made the occasion for this reunion of his friends. The menu was elaborate and was thoroughly enjoyed from the cocktail, labeled "The Will Loring Welcome," to the "ice cream Martin (of Angels, not New York)." The fruit salad, of course, was "Melones", while the venison was naturally "sauce Bret Harte." The attractive menu cards were decorated with a reproduction of the famous 'Miners Ten Commandments' which will bear reprinting for the benefit of the present generation:

MINERS' TEN COMMANDMENTS

A man spake these words, and said: I am a miner, wandering "from away down east," to sojourn in a strange land. And behold, I've seen the elephant, yea, verily, I saw him, and bear witness, that from the key of his trunk to the end of his tail, his whole body hath passed before me; and I followed him until his huge feet stood still before a clapboard shanty; then with his trunk extended he pointed to a candle-card tacked upon a shingle, as though he would say, read, and I read the

MINERS' TEN COMMANDMENTS

I.

Thou shalt have no other claim than one.

II.

Thou shalt not make unto thyself any false claim, nor any likeness to a mean man, by jumping one: for I, a miner, am a just one, and will visit the miners around about, and they will judge thee; and when they shall decide, thou shalt take thy pick, thy pan, thy shovel, and thy blankets with all thou hast and shall depart seeking other good diggings, but thou shalt find none. Then when thou hast paid out all thy dust, worn out thy boots and garments so that there is nothing good about them but the pockets, and thy patience is like unto thy garments, then in sorrow shalt thou return to find thy claim worked out, and yet thou hast no pile to hide in the ground, or in the old hoot beneath thy bunk, or in buckskin or bottle beneath thy cabin, and at last thou shalt hire thy body out to make thy board and save thy bacon.

III.

Thou shalt not go prospecting before thy claim gives out. Neither shalt thou take thy money, nor thy gold dust, nor thy good name, to the gaming table in vain; for monte, twenty-one, roulette, faro, lasquenet, and poker, will prove to thee that the more thou puttest down the less thou shalt take up; and when thou thinkest of thy wife and children, thou shalt not hold thyself guiltless—but insane.

IV.

Thou shalt not remember what thy friends do at home on the Sabbath day, lest the remembrance may not compare favorably with what thou doest here. Six days thou mayst dig or pick; but the other day is Sunday; yet thou washest all thy dirty shirts, darnest all thy stockings, tap thy boots, mend thy clothing, chop thy whole week's firewood, make up and bake thy bread, and boil thy pork and beans, that thou wait not when thou returnest from thy long-tom weary. For in six days' labor only thou canst not work enough to wear out thy body in many years; but if thou workest hard on Sunday also, thou canst do it in six months; and thou, and thy morals and thy conscience, be none the better for it; but reproach thee, shouldst thou ever return with thy worn-out body to thy mother's fireside.

V.

Thou shalt not think more of all thy gold, and how thou canst make it fastest, than how thou wilt enjoy it after thou hast ridden rough-shod over thy good old parents' precepts and examples, that thou mayst have nothing to reproach thee, when left alone in the land where thy father's blessing and thy mother's love hath sent thee.

VI.

Thou shalt not kill; neither thy body by working in the rain, even though thou shalt make enough to buy physic and attendance with; nor thy neighbor's body in a duel, or in anger, for by "keeping cool" thou canst save his life and thy conscience. Neither shalt thou destroy thyself by getting "tight," nor "slewed," nor "high," nor "corned," nor "half-seas over," nor "three sheets in the wind," by drinking smoothly down—"brandy slings," "gin cocktails," "whiskey punches," "rum toddies," nor "egg-nogs." Neither shalt thou suck "mint juleps," nor "sherry cobblers," through a straw, nor gurgle from a bottle the "raw material," nor take "it straight" from a decanter; for, while thou art swallowing down thy purse, and the coat from off thy back, thou art burning the coat from off thy stomach; and, if thou couldst see the houses and lands, and gold dust, and home comforts already lying there—" a huge pile"—thou shouldst feel a choking in thy throat; and when to that thou addest thy crooked walkings thou wilt feel disgusted with thyself and inquire "Is thy servant a dog that he doeth these things!" Verily, thou shalt say, "Farewell, old bottle, I will kiss thy gurgling lips no more; slings, cocktails, punches, smashes, cobblers, nogs, toddies, sangarees, and juleps, forever farewell. Thy remembrance shames me; henceforth, I cut thy acquaintance, and headaches, tremblings, heart-burnings, blue devils, and all the unholy catalogue of evils that follow in thy train. My wife's smiles and my children's merry-hearted laugh, shall charm and reward me for having the manly firmness and courage to say No. I wish thee an eternal farewell."

VII.

Thou shalt not grow discouraged, nor think of going home before thou hast made thy "pile," because thou hast not "struck a lead," nor found a "rich crevice," nor sunk a hole upon a "pocket," lest in going home thou shalt leave four dollars a day, and go to work, ashamed, at fifty cents, and serve thee right; for thou knowest by staying here, thou mightest strike a lead and fifty dollars a day, and keep thy manly self-respect, and then go home with enough to make thyself and others happy.

VIII.

Thou shalt not steal a pick, or a shovel, or a pan from thy fellow-miner; nor take away his tools without his leave; nor borrow those he cannot spare; nor return them broken, nor trouble him to fetch them back again, nor talk with him while his water rent is running on, nor remove his stake to enlarge thy claim, nor undermine his bank in following a lead, nor pan out gold from his "riffle box," nor wash the "tailings" from his sluice's mouth. Neither shalt thou pick out specimens from the company's pan to put them in thy mouth or pocket; nor cheat thy partner of his share; nor steal from thy cabin-mate his gold dust, to add to thine, for he will be sure to discover what thou hast done, and will straightway call his fellow-miners together, and if the law hinder them not, will hang thee, or give thee fifty lashes, or shave thy head and brand thee, like a horse thief, with "R" upon thy cheek, to be known and read of all men, Californians in particular.

IX.

Thou shalt not tell any false tales about "good diggings in the mountains," to thy neighbor, that thou mayst benefit a friend who hath mules, and provisions, and tools and blankets he cannot sell—lest in deceiving thy neighbor, when he returneth through the snow, with naught save his rifle, he present thee with the contents thereof, and like a dog, thou shalt fall down and die.

X.

Thou shalt not commit unsuitable matrimony, nor covet "single blessedness"; nor forget absent maidens; nor neglect thy "first love";—but thou shalt consider how faithfully and patiently she awaiteth thy return; yea, and covereth each epistle that thou sendest with kisses of kindly welcome—until she hath thyself. Neither shalt thou covet thy neighbor's wife, nor trifle with the affections of his daughter; yet, if thy heart be free, and thou dost love and covet each other, thou shalt "pop the question" like a man.

A new commandment give I unto thee—if thou hast a wife and little ones, that thou lovest dearer than thy life,—that thou keep them continually before thee, to cheer and urge thee onward, until thou canst say, "I have enough—God bless them—I will return." Then from thy much-loved home, with open arms shall they come forth to welcome thee, with weeping tears of unutterable joy that thou are come; then in the fullness of thy heart's gratitude, thou shalt kneel together before thy Heavenly Father, to thank him for thy safe return. AMEN. —So mote it be. FORTY-NINER.

Fred G. Stevenot presided most happily as toastmaster and introduced, as the first speaker, F. J. Martin, the well known manager of the Utica mine. He spoke briefly of the days when Mr. Loring was foreman in the Utica mill and of his

later successes in various parts of the world, including that just consummated at Plymouth. He closed by expressing the hope that Mr. Loring might turn his attention to Calaveras county, not only that its latent resources should be developed, but in order that he might again make his home among them. H. Foster Bain followed with an expression of appreciation of Mr. Loring's work and of the coming together of so many mining men. He expressed the hope that the Mother Lode operators would form the habit of meeting and dining together. G. McM. Ross called attention to the fact that the disturbed conditions in Europe were likely to prevent for some time the influx of foreign capital and that Mother Lode operators would have to depend upon their own initiative and resources for further development. He called attention to the work being done at the Melones in cyaniding sulphides, and suggested that by proper selection of properties and of ore it would be possible to go on with local development despite the stringency of the money market. Allen Chalmers of the Lightner mine recalled Mr. Loring as a young mill-man and expressed the wish that there were more like him. C. H. Edwards, of Fresno, spoke of the plans for a mineral exhibit at the Panama-Pacific Exposition and the wish of the authorities for the hearty coöperation of the mining men. C. H. Segestrom, of the Dutch mine, expressed the pleasure of the Tuolumne operators in joining in the home-coming celebration. J. F. Davis, in an eloquent and witty address, called attention to the famous men other than Mr. Loring, including Bret Harte and Mark Twain, who had helped to make Calaveras county famous. Dr. G. W. Pache, on behalf of the Chamber of Commerce, expressed the good wishes of those not directly connected with mining.

In his reply, Mr. Loring, in well chosen words, expressed his gratitude for the welcome extended him and his pleasure at meeting old friends. He stated that upon visiting California three years ago, Albert Burch had brought to him the project of reopening the mine. After examining a collection of Mother Lode maps and data placed at his service by F. W. Bradley, and having the whole lode examined in general by Malcolm Maclaren, his firm had decided to undertake the venture. Before building the mill just opened, $180,000 was spent upon equipment and development and at present there was $530,000 invested in the project aside from purchase price. Fortunately, development had justified the expenditure since, whereas at the beginning the workings on the 1600-ft. level showed a vein 16-ft. wide and of no value, two ore-shoots were now known from 1500 to 2000-ft. of ore averaging $7 to $10 per ton and all of workable width. On the 2000-ft. level one shoot 160 ft. long showed 22 ft. of $15 ore. In all, 120,000 tons was blocked out when building began. All this is in new ground. The new mill started August 1, dropping 20 stamps, and in 15 days the return was $11,240 in gold and $2800 in concentrate. Mr. Loring expressed his confidence in the development of the Mother Lode in depth provided work followed lines indicated by the old ore-shoots. He made a strong plea for publicity in mining, stating that in Western Australia, coincident with the adoption of the policy of publishing regular returns and free exchange of information among managers, there was a marked drop in mining costs. He also insisted upon the value of careful scientific work both in exploration and in operation of mines and urged his hearers not to live in a fool's paradise of ignorance. He announced that the Plymouth Consolidated would make frank and full statements of such results as the management obtained, and if mistakes were made would accept the responsibility.

At a late hour the gathering adjourned with many expressions of pleasure at the success of the assemblage.

[Later advices indicate that the duty per stamp at the Plymouth mill is now 17½ tons per 24 hours. The stamps weigh 1250 lb. and crush to ¼-in. size. There is no by-pass. For description of the mill, see page 329.—Editor.]

TORONTO, ONTARIO

Oil Companies and Operations in Calgary.—Coal on Hudson Bay.—Cobalt Silver Situation.—Porcupine District.

The number of oil companies incorporated in Alberta up to the close of July was about 450, representing an aggregate authorized capitalization of $400,000,000. Only a comparatively small percentage of these have been able to obtain sufficient subscriptions to enable them to proceed with active development work. Fifteen companies are actually drilling, and have reached depths ranging from 400 to 2700 ft. Twenty more are making preparations to sink wells, and about a score of others have secured sufficient working capital, and expect to put down wells this fall. The standard drills, which have been used hitherto, the process of which is very slow, are being superseded by the diamond rotary drills, a number of which are already in operation and more on the way. They have the reputation of being able to bore a 3000-ft. well in 30 days. The cost is on average $15 per foot, and as 3000 ft. is the depth at which petroleum is expected to be found, the expense of putting down a well is placed at $45,000. A large field is covered by the undertakings now in hand, and it is felt that if there is a big oil deposit located in the foothills of southern Alberta, one of the companies now drilling or arranging to do so will certainly find it.

Mackenzie & Mann, of the Canadian Northern railway, are sending out an expedition from St. John, Newfoundland, by the schooner *Laddie* to prospect for coal along the shores of Hudson Bay. It is of vital importance to the traffic which it is expected will be created by the construction of the Hudson Bay railway, that coal supplies should be obtainable near its northern terminus at Port Nelson. The Canadian Northern railway has a junction at Le Pas, from which point the railway is being constructed northward to Port Nelson. It is proposed to provide at that point extensive storage facilities for coal. At present, coal required for the steamship traffic to Hudson Bay has to be freighted from Sydney, Nova Scotia, and the coal needed in connection with the construction of the railway has to be brought from Winnipeg. The discovery of coal deposits at any point accessible for ships plying on the Hudson Bay route would be of immense advantage.

The sudden decline in the price of silver, owing to the European war, is beginning to affect the output of the Cobalt camp. There is a disposition on the part of mine managers to curtail production, especially in cases where there is only a narrow margin between operating expenses and the returns from smelters, which may at any time be entirely wiped out. The financial stringency prevailing will render it a matter of difficulty to find funds for the development of mines which have not reached the productive stage. The most important feature of the situation is the new departure taken by La Rose Consolidated and the Nipissing companies, which have followed the example of other Cobalt concerns by entering the goldfields. La Rose has secured a working option on the Kensy claim in Boston township, just south of Swastika. As the cash surplus is $1,435,000, it will have ample funds for the thorough development of the property. The Nipissing has taken over on option the Teck-Hughes property at Kirkland Lake, and will expend a large amount in development. On the 75-ft. level, an ore-shoot 120 ft. long and 3 ft. wide, assaying $42 to the ton has been cut.

The work of centralizing operations on the group of Porcupine properties controlled by the Canadian Mining & Finance Co., including the Hollinger and the Acme, is progressing. The 20-stamp addition to the Hollinger has been completed, and foundations will shortly be laid for the 20 stamps to be reserved for ore from the Acme, which has enough ore blocked out to keep them in operation for some time. The combined plant will have a capacity of about 1000 tons per day. The main vein of the Hollinger has been cut at the 675-ft. level.

VICTORIA, BRITISH COLUMBIA

MINERAL OUTPUT IN 1913.—DIVIDENDS FOR 1914.—WORK IN THE CARIBOO, CASSIAR, EAST AND WEST KOOTENAY, SLOCAN, NELSON, ROSSLAND, AND BOUNDARY DISTRICTS.

The annual report of the minister of mines of this province for 1913 shows that the total value of the mineral production for that year was $30,296,398, the revised figures giving a total $137,605 higher than that of the estimate published about the middle of January. As compared with 1912, there was a decrease of $2,144,402, due to two main causes, namely, labor troubles at Vancouver Island coal mines, which prevented production of coal on the customary scale, and the generally lower grade of the great bulk of copper ore mined and smelted.

Dividends declared during the seven expired months of 1914, by metalliferous mining companies operating in British Columbia make a total as follows:

Consolidated Mining & Smelting Co.	$232,176
Granby Consolidated M. S. & P. Co.	449,955
Hedley Gold Mining Co.	120,000
Standard Silver-Lead Mining Co.	400,000
Total	$1,202,131

The Consolidated company's profit distribution is at the rate of 8% per annum; the Granby company's at 6%, the Hedley company's at 20%, and the Standard company's totals 20c. per share for the seven months on 2,000,000 shares, having a par value of $1 each. The Hedley company has in past years distributed 5% at the close of each of three quarters, and 15% for the fourth quarter, which course, it is expected, will also be followed this year.

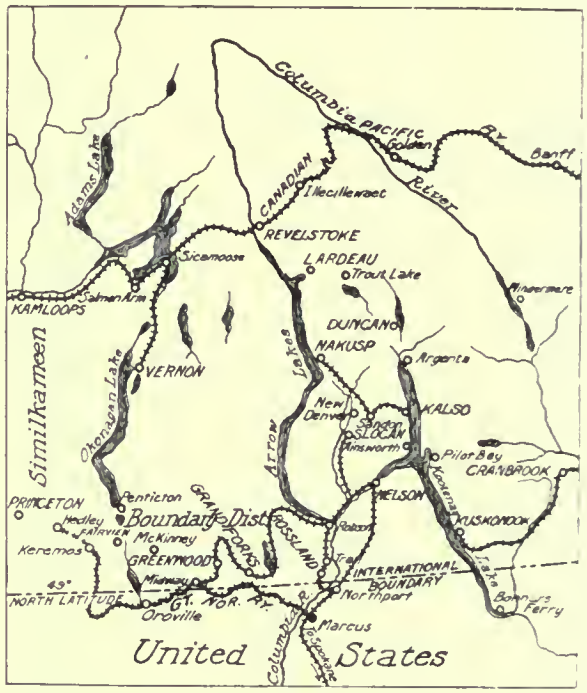
Of the three divisions of the Cariboo district, Cariboo yields most placer gold. This season the John Hopp hydraulic mines are again in the lead in respect of quantity of gravel being washed and gold recovered. Quesnel division is not likely to yield as much as one fourth of the Cariboo division total, while in Omineca the season's work will again be chiefly preparatory, with little actual gravel washing.

Placer-gold mining on eight or ten streams in Atlin camp constitutes the most important phase of mining in the Cassiar district this year, as for all other years since 1897. Men in varying numbers are busy on McKee, Pine, Spruce, Birch, Boulder, Ruby, Otter, and others creeks, while on O'Donnell river and several tributary creeks there is considerable activity, in some measure recalling the early days of the Atlin diggings, when much more gold was taken out than in later years. As the construction of the Telegraph creek to Dease lake wagon road becomes further advanced, transportation difficulties are lessened, so placer mining on Dease and Thibert creeks in Liard division is less costly. Some lode-gold mining is being done in the neighborhood of Taku arm of Tagish lake, Atlin division.

Coal mining is not keeping the miners occupied full time in Crows Nest district, the demand for coal not being sufficient to give them constant employment. The Hosmer mines have been abandoned, and plant and machinery is being removed, disturbed country and consequent broken coal having caused increasing loss to the Canadian Pacific Railway Co. owning the mines. Reports of new placer gold finds on several streams have led to claim-staking, but little gold has yet been obtained. Some placer mining is again being done this year on Wildhorse, Perry, and other creeks. During seven months, to the end of July, approximately 13,000 tons of lead ore has been shipped to Trail from the Sullivan Group mines, and 750 tons from the St. Eugene. Construction of the Kootenay Central railway is well advanced; this will lead to more metalliferous mining being done in the district it passes through.

The Highland No. 1, and Bluebell mines, in West Kootenay, are steadily maintaining production and shipping silver-lead ore and concentrate to Trail. A small power-plant has been put in at the Silver Hoard, at which, and at the Florence company's property preparations for ore production are being made. Now that the Kaslo & Slocan railway has been reopened, the Cork, Utica, Retallack, and other mines will take advantage of the restored transportation facilities.

Among Slocan mines, the Rambler-Cariboo is keeping its concentrating plant going without intermission; exploration work is being continued at the Payne, but not much ore has yet been found in the deep of the mine; the Slocan Star concentrator is producing silver-lead and silver-zinc concentrate, and shipment of these products as well as of sorted crude silver-lead ore is being made; the Ruth-Hope, Richmond-Eureka, and Wonderful mines, all near Sandon, are being worked; concentrating plant is being put in for the Surprise, and at its neighbor the Noble Five, deep-level development is being continued; another strike of ore in the Reco is reported; the Standard is keeping up its profitable production and paying dividends regularly; the Hewitt-Lorna Doone group has been supplied with concentrating facilities for treating 150 tons of ore per day, while a dozen other Slocan mines are being worked.



MAP SHOWING MINING DISTRICTS OF BRITISH COLUMBIA NEAR THE UNITED STATES BOUNDARY.

In Nelson division, the Silver King's output of copper-silver ore during the expired seven months of the year has reached a total of more than 12,000 tons; the Molly Gibson is again active after the winter suspension, the deep snow having melted; the outlook for Ymir camp is brighter, ore having been proved to occur in considerable quantity in the Wilcox, Dundee, and Yankee Girl mines; the Motherlode and Queen gold mines on Sheep creek are busy; in the latter a big shoot of ore is being mined on the 600-ft. level; the Emerald and H. B. lead mines are shipping regularly to Trail; and work is in progress at the Second Relief at Erie.

Rossland mines are maintaining their output, shipments to Trail during seven months to August 1 having been, approximately: Centre Star group, 92,000 tons; Le Roi, 40,000 tons; and Le Roi No. 2 company's Josie group, 12,000 tons. All three properties are looking well, each having much good ore in its lowest workings. More additions and improvements are

being made at the Consolidated company's smelting works at Trail, including a second large copper blast-furnace and a third lead stack in place of old furnaces removed; starting of two Wedge roasting furnaces; experimenting with the Cottrell fume condensation system; construction of a 250-ft. high reinforced concrete smokestack; and other betterments.

The larger copper mines of Boundary district continue to make a big production; the Jewel gold mine and mill are being worked steadily; ore is hauled in wagons from the Union mine, Franklin camp, to Lynch creek, and thence by railway, a total distance to Grand Forks of about 50 miles. In Similkameen district, the Hedley Gold Mining Co. is mining and milling 6000 tons or more of gold ore every month and is making good progress with construction work in connection with its new hydro-electric power system; the New York Syndicate No. 2 is again diamond-drilling on claims near the Nickel Plate group; the B. C. Copper Co.'s exploration work on Copper mountain has shown that much ore occurs there, estimated at 5,000,000 tons at least; and placer-gold mining, coal mining, and cement making are all having attention in the district. Coal mining in Nicola valley is being continued. In the neighborhood of Kamloops, the Iron Mask group is sending out an occasional shipment of copper-gold ore.

In the Coast district, the most important metal mining enterprises are those of the Britannia and Granby companies, respectively, but notice of these and other mining operations in this district must be deferred until later. There is, however, more activity in metalliferous mining now than for several years. Coal mining is not generally flourishing, last year's lack of production having caused the loss of markets to the mining companies. Strike pay having been stopped by the U. M. W. of A., the strikers now realize that they have lost in their struggle with the operators.

[Since the above notes were written, numbers of copper and other metal mines have been shut down, but with a better metal market some are certain to resume.—Editor.]

NEW YORK

Present Situation in Copper, Tin, Quicksilver, Cyanide, Zinc Dust, Pebbles, and Spelter.

The war continues to engross the attention of everyone. There is no market in securities, no one is attempting to float any new companies, of course, and everyone is endeavoring to adjust themselves to the new conditions brought about by the European war. Shipments of copper to Europe are being gradually resumed, and 9472 tons of the metal was exported during the first 20 days of August. Freight and handling rates have come back to about 2¼c. per pound, and insurance rates have been reduced from 15% to 5%, so that it has become easier to get copper across the water to fulfill contracts. It must be remembered, though, that nearly half the United States exports go to Germany, so that with output here cut to one-half normal, it still seems probable that copper stocks will continue to grow for some time to come.

It must not be forgotten that, although the production was cut almost immediately upon the stoppage of exports, there was at that time three months of full-scale smelter production in the course of its routine from the smelters through the refineries, so that even were domestic consumers buying at their normal rate (which they are not), there would still be 150,000,000 lb. of copper for the producers to carry as stocks until exports can be resumed. To meet this critical situation, the selling agencies have declared what practically amounts to a 'moratorium,' by making no quotations for the time being. In this way the utter collapse of the copper market, which would do nobody any good, and would do some a great deal of harm, has so far been effectually prevented. The move has been effective, and small lots of copper are being sold at 12¼c., as compared with London quotations of 13½c. It is reported that the Calumet & Hecla will continue to work full time and will carry its accumulated stocks until they can be disposed of. As the Calumet & Hecla is an exceedingly powerful organization financially, it may be in a position to do so, but many of the other companies could not follow such a course of action even if they would. If everybody tried to keep going now, the inevitable result would be that the market would finally break so badly that nearly everybody would have to call a halt. The Mohawk and Wolverine are reported to have made a wage decrease of 10% with the intention of continuing work with a full force. Most of the copper-mining companies throughout the country have cut their output to one-half of normal. It is interesting to note that the suggestion now comes from London that the heavy copper consumption in Europe for the past year was caused by the manufacture of ammunition in Germany, the government of that far-seeing country having perceived that settlement of the Balkan troubles was not likely to be permanent, and accordingly prepared for war in times of peace.

Tin has begun to decline in price, having gone down again to 45c. per pound on August 20. This reflects confidence in British shipping being resumed on more nearly normal basis soon, though the Suez canal is said to be jammed with ships which are afraid to venture out into the waters on either side where hostile cruisers may be lurking. Now that the Panama canal is open, the 30,000 to 40,000 tons of tin concentrate which is shipped each year from Bolivia for smelting may be diverted here. There is actually a tin smelter already in existence near New York, for it was proposed to smelt tin at Bayonne, New York, some years ago. There is also a small plant at Long Island City. Tin smelting is a rather simple matter, and does not require very elaborate plant, so that if any of the smelting companies want to take advantage of the present situation, it would not be difficult to do so.

Quicksilver has gone up with a jump. The Austrian production is cut off as a result of the war, while the demand for the metal for making fulminate for caps has caused it to score a sharp advance. The production of Europe is completely controlled by the Rothschilds, who will make nice profits for the time being, in which the American independents will have some share, at least. It is an odd thing that the increase in the 'cost of living' is felt most seriously by the gold producers, who cannot increase the selling price of their product. The mercury they use for amalgamation has almost tripled in price, pebbles for grinding the ore previous to cyaniding will be more expensive, if they can be obtained at all, and the same is true of cyanide, both of these necessaries coming from Europe. Those who have protected themselves with advance contracts are therefore wondering if they can get supplied. Zinc dust is another necessity of many cyanide plants that will certainly advance in price, as it has so far nearly all been imported. The smelters in this country have promptly begun to produce it, and ample supplies will soon be available, though doubtless at a somewhat advanced price.

The Butte & Superior management is gleeful over the advance in the price of spelter, as the 1c. advance in the price recently made practically doubles the net earnings. The situation illustrates the truth of the old adage about not having all the eggs in one basket, since the war has made a tremendous decrease in the profits of the copper mines held by the same group, but partly makes it up in the form of increased profits on spelter. The same group is developing a large gold mine in the Juneau district, Alaska, and when that is producing can be practically sure of some profits under any stress of fortune.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

According to J. Horsfield, who recently returned to Cordova, the Chisana district should show a good deal of pay-gravel in time. The latest scheme is to operate a hydraulic plant on Johnson creek and the flats. By consolidating certain properties it is expected that next summer considerable work will be done in this way. Men who are interested in this project, he says, are Hamshaw, Wiley, James, Nelson, Baldwin, Noyes, Irving, and others. A drill is now being taken in from White Horse and will be used this winter for prospecting.

Fairbanks

Rain has swollen rivers in the Tanana valley, the highest since 1905, and considerable damage was done last week at Fairbanks.——Two U. S. Government commissioners, Frederick Mears and Thomas Riggs, Jr., in charge of railway routes from Fairbanks to the coast, left here on August 22 for Ship creek. They state that surveys are nearly finished and preliminary estimates will be ready in a few weeks. They favor a route from Portage bay to Fairbanks by way of the Matanuska coalfields, Susitna and Neana rivers. The cost will be about $20,000,000.

Juneau

The Alaska Mexican, Treadwell, and United companies, on August 28, paid dividends of 20c., $1, and 20c. per share, respectively.

Wrangell

Barite, or barytes, or heavy spar, a barium sulphate, occurs on one of the Castle islands in Duncan canal, 40 miles northwest of Wrangell, according to Ernest F. Burchard in *Bulletin* 592-D of the U. S. Geological Survey. The deposit is possibly 75 by 200 ft. in area and 140 ft. thick, it standing up 35 ft. above high-tide level, and contains about 50,000 tons above high water. The mineral occurs mainly in schist, and where fresh is mostly a finely crystalline grayish white rock, with thin grayish blue veins and clouded areas, and a few thin black streaks. Pyrite is present nearly everywhere, and assays show low percentages of gold, silver, copper, lead, and zinc. Barite is used principally as a pigment in mixed paints, and for many other manufactures. The deposit is not of the highest grade, but is valuable, and could be shipped to Puget Sound or San Francisco. The output of the United States in 1913 was 45,298 tons, worth $156,275, while imports of crude barite were 35,840 tons, worth $61,409.

ARIZONA

Cochise County

On August 13 the new test plant at the Copper Queen mines was started, and a capacity of 120 tons per day is expected in a few days. The ore to be treated consists of chalcocite and chalcopyrite, containing from 1 to 3% copper, the gangue being a granite-porphyry. The ore will come from the Holbrook mine under Sacramento hill through the Neptune tunnel and Holbrook 200-ft. level. The mill flow-sheet is as follows: 50-ton storage bins, a Tekmith conical crusher reducing the ore to 1½ in., bucket elevator, 50-ton bin, belt conveyor over automatic scale, sampling system, a two-stage revolving trommel with ¾ and ⅜-in. mesh screens, oversize through rolls and back to smaller screen, Hartz jig, National table, tailing and middling from jig and table to classifier, fine pulp to three conical settling-tanks, coarse material to a Hardinge mill, and further classification and concentration. A flotation process to recover more concentrate is being considered. The rolls, screens, jig, etc., are driven by a 112-hp. General Electric motor, and 10-hp. motor drives the tables and vanners. Churn-drilling on Sacramento hill has been suspended temporarily, after 36 holes were drilled averaging 400 ft. in depth, and totaling about 15,000 ft. The installation consists of two Armstrong electric churn-drills, and one steam drill, in charge of a runner, helper, and sampler on each 8-hour shift. Each machine drilled from 25 to 30 ft. per shift. Two more Armstrong machines have arrived on the ground. Capping over the orebody is about 100 feet.

Greenlee County

Owing to the war the Arizona Copper Co. has suspended operations in mining oxidized ore at Metcalf, the Clifton concentrating plant, leaching plant, and acid plant. About 400 men have been discharged from all departments.——At Morenci, the Detroit Copper Co. has stopped work at the Santa Rosa, Summit, Wattles, and Fairbanks properties, all in the development stage. Production at the concentrator and smelter has been cut about 30%. Wages have been reduced 10%. ——A reduced force is working at the Shannon Copper Co.'s works.——The store departments of the above companies will supply the people of the district with goods at the lowest possible price.

Santa Cruz County

Lightning is supposed to have set afire and destroyed the concentrating plant at the old Mowry mine, damage being about $100,000. The mill formerly treated silver-lead ore, but has not worked for over six years.

CALIFORNIA

The value of the recoverable gold, silver, copper, lead, and zinc produced at mines in California in 1913, according to Charles G. Yale, of the U. S. Geological Survey, was $26,812,489, compared with $26,383,946 in 1912, and $25,174,677 in 1911. Except in zinc, there was an increase in the output

NORTH STAR MILL, GRASS VALLEY, CALIFORNIA.

of all these metals, although the tonnage from deep mines showed a decline and there were fewer mines reporting production than in 1912. The mine production of gold in 1913 was $20,406,958, $693,480 more than in 1912, an increase of 3.52%. The deep mines of the state produced $11,570,781, or

56.70% of the total. The increase in gold from deep mines for the year was $502,966, or 4.54%. The placer mines produced $8,836,177 in gold, an increase of $190,514, or 2.20 per cent.

This output of gold in California was the largest in 31 years, the yield in 1883 having been $24,313,873. Only three times in 49 years has the gold output exceeded $20,000,000, and if the year 1883 is excluded, the gold output in 1913 was higher than it has been since 1864. The gold is now the annual output from gold dredges reached in 1913 the sum of $8,090,294, which is 39.64% of the total gold yield of the state, and 91.56% of the total output of placer gold. The hydraulic mines produced $329,300, or 3.73% of the total production of gold in the state in 1913; the drift mines produced $192,538, or 2.18%; and the surface or sluicing mines produced $224,045, or 2.53 per cent.

There were 410 deep mines reporting production in 1913, a decrease of 122 compared with 1912. A total of 2,495,958

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA IN 1913, BY COUNTIES

County.	No. of producers.	Ore treated. (Short tons.)	†Gold. (Value.)	†Silver. (Fine oz.)	Copper. (Pounds.)	Lead. (Pounds.)	Total value.

*Dredge production combined to conceal output of single dredges.

†Includes placer production.

The recoverable zinc production amounted to 1,057,485 lb. in 1913 (compared with 4,345,591 lb. in 1912), of which Inyo county yielded 963,571 and Shasta county 93,914 pounds.

derived from extensive operations, rather than from efforts of individuals or numerous small enterprises. Some of the deeper quartz mines are working as good ore at vertical depths of 3000 to nearly 4000 ft. as was found near the surface. The dredges are now producing 91.56% of the placer gold from ground which was formerly considered worthless for mining, as being too poor in gold, having no 'fall' or no drainage, and on which water could not be used advantageously on any scale under the old systems of gravel mining. There are now 63 dredges in operation in California, and since the beginning of operations with these machines in the state, 15 years ago, the dredge gold output has reached a total of $63,505,485. From a production of $206,302 in 1899, tons of ore, was treated in 1913, a decrease of 145,539. The silicious ore treated at gold and silver mills, amounted to 1,905,258 tons, yielding $8,469,245 in gold, or $1.41 per ton in bullion. From this ore was derived 32,652 tons of concentrate, which contained $2,063,656 in gold, or $63.20 per ton. The average value in gold and silver in the ore milled was $5.57 per ton, of which $5.52 was in gold and 5c. in silver. The 531,189 tons of ore sent to smelters produced $810,030 in gold, or $1.58 per ton; and the treatment of 59,511 tons of old tailing yielded $197,850 in gold, or $3.32 per ton. Of the total recovery of gold in bullion from ore treated at gold and silver mills, $1,025,279 was won by direct cyanidation, and $7,413,966 by amalgamation. The total recovery of gold by the cyanide

process, including that recovered by the treatment of old tailing, was $1,289,353.

The two largest deep-mine gold districts are Grass Valley (including Nevada City) in Nevada county, and Jackson (including Sutter Creek) in Amador county, and it is due to these two that the counties of Nevada and Amador ranked first and second, respectively, in 1913 in gold production. In the Jackson district 448,269 tons of ore was treated, yielding $2,117,962 in gold, or $4.72 per ton, and $13,402 in silver, or $0.03 per ton, making a total production of $2,131,364 in gold and silver, or $4.75 per ton. In the Grass Valley district, 252,607 tons of ore was treated, yielding $2,830,661 in gold, or $11.21 per ton, and $26,082 in silver, or $0.10 per ton, a total production of $2,856,743 in gold and silver, or $11.31 per ton. Three other counties had a production of more than $2,000,000 in gold, namely: Sacramento, $2,503,633; Yuba, $2,491,505; and Butte, $2,269,849. These three counties owe their large production of gold to the dredging industry, from which the bulk of their gold is derived. The most productive metal district in the state in 1913 was Kennett, in Shasta county, where the largest smelter in California is situated. The total output at Kennett was 280,657 tons of ore containing recoverable values in gold, silver, and copper amounting to $3,716,430, or $13.24 per ton.

Amador County

Arrangements are being made by A. A. Krogdahl, of the U. S. Bureau of Mines, for a first-aid field meet at Jackson on Labor Day, Monday, September 7. It is expected that about 15 first-aid teams from the Mother Lode district will enter the contests and that prizes will be awarded the winning teams by the American Mine Safety Association and the operators and miners of the district. As a result of Mr. Krogdahl's work in coöperation with the Industrial Accident Commission, a great deal of interest has been aroused in first-aid-to-the-injured practices in the mining districts. Meets like the one mentioned above will stimulate interest and result in much permanent good.

COLORADO

Lake County (Leadville)

All of the important mines of the district are working as usual, and no changes are expected at present at the Ibex, Wolftone, Henriette, Colonel Sellers, Iron Silver, New Monarch, and Yak properties.——On August 13 a mysterious fire, in which dynamite exploded, destroyed the engine-room and plant at the Evening Star No. 5 mine on Carbonate hill. This ground is leased from the Star Consolidated Mines Co., in charge of E. D. Dickerman, by George E. Cramer. A new electric hoist and compressor had only recently been installed. The motor bore every sign of having been purposely dynamited.——From 102 pounds of ore, Connor's lease at the Little Jonny mine returned $8192. The full shipment of 2 tons assayed 171 oz. gold per ton.

Ouray County

The Wanakah Mining Co.'s smelter matte silver content, which is sold to the Garfield plant in Utah, is being settled at 52c. per ounce, and the local plant will settle for silver on that basis.——At a meeting of the Mountain Top Mining Co. on August 17, the old directors were reëlected, namely, J. H. Chambert, George H. Beebe, E. C. L. Bartow, William Story, Jr., Fred Carroll, E. A. Krisher, and G. H. Barnhart.——The Torpedo-Eclipse property in the Sneffels district was sold last week at a sheriff's sale to J. G. Tracy, on an order of the District Court, for $26,000.

Teller County (Cripple Creek)

According to George A. Taylor, mill superintendent of the Portland company, a six months supply of cyanide is on hand for its mill here and at Colorado City. The Golden Cycle also has several months supply.——The Elkton company paid a quarterly dividend of 2%, or $50,000, on August 24.——The Golden Cycle company has paid its monthly dividend of 3%, or $45,000.

IDAHO

Mineral County

Near the town of Saltese a new adit is being driven in the Monitor mine. This work will cut the vein at a great depth, and afford cheaper mining and transport than in the past.

Shoshone County

Officials of the various mining companies in the Coeur d'Alene met in Wallace last week, and discussed the lead, silver, zinc, and copper markets, to determine a possible plan regarding the operation of the mines and mills. No final decision was arrived at, although work has been curtailed at several properties, including the Morning, Missoula, National, Bunker Hill & Sullivan, Hecla, Last Chance, and others.

In cutting a station above the old shaft of the Castle Rock, near Wallace, high-grade copper ore, with some gold and silver, has been opened. A shipment of 45 tons is ready for the Tacoma smelter.——A winze is being sunk below the lower adit of the Great Western, north of Burke. Ore in this mine contains lead, copper, silver, and gold.——A flotation process has been tried by the Hunter company at Mullan, on an ore composed of heavy spar with rich sulphides of lead and silver, which has always been troublesome to concentrate by ordinary methods. A product assaying 43% lead and 500 oz. silver was saved, the tests being highly satisfactory.——The Stewart Mining Co.'s report for the past half-year shows a profit of $537,230; dividends paid, $247,672; and surplus, $1,105,366, of which $815,808 was on hand at the end of 1913. The annual meeting of the Company was to be held at Kellogg, August 29.

Ore and concentrate shipped to smelters from the Coeur d'Alene district in July was as follows:

Mines.	Tons.	Mines.	Tons.
Hercules	6,000	Sierra Nevada	1,200
Bunker Hill & Sullivan	5,200	Success	1,400
Morning	4,500	Gold Hunter	1,020
Green Hill-Cleveland	3,300	Ontario	1,000
Stewart	3,500	Snowstorm	1,000
Interstate-Callahan	2,300	Crown Point	100
Hecla	1,700	Caledonia	700
Last Chance	2,000	Yankee Boy	50
Tamarack & Custer	1,300		
		Total	36,270

This was only 3000 tons below the monthly average, in spite of several shut-downs.

In order to produce more zinc ore, the Interstate-Callahan company has engaged 100 extra miners; while the Success and Tamarack have increased their working force.

MICHIGAN

Houghton County

(Special Correspondence.)—It is said that the Calumet & Hecla company will not cut wages, and if curtailment is a necessary expedient, half-time work will be instituted. Another interesting feature is the fact that the worst possible conditions would not permit shutting down the conglomerate shafts of the old Calumet & Hecla mine. They will be kept working and operating regardless of conditions. Such action practically is necessary, because of the great depth of the shafts, and the cost of maintenance of the pump service. It would be out of the question to permit these shafts to fill with water. It is interesting to know that practically all of the mining being done in these shafts is in the hands of men who have served the Company for long terms of years and are counted as the most efficient miners in the world, and would not be discharged unless exceptional circumstances arose.——Sinking to No. 26 level is under way at the Victoria

mine, and ore is being stoped from below No. 24.——Tributers in the Michigan mine are taking out mass copper.

Houghton, August 20.

MISSOURI

Jasper County

The market for ores in the Joplin district was strong during the week ended August 15, and showed sharp advances. Zincblende was $6 per ton higher, $45 to $48 being paid for basis of 60 and 63% metallic zinc. Many producers are holding for $50. Prices at St. Louis rose to 5.75c. per pound for the metal. Calamine is bringing $21 to $22 per ton for ores with 40% zinc. A rise is expected in lead, but no strength has been developed yet. The output for the 33 weeks of the year to date was blende, 161,404 tons; calamine, 10,363 tons; and lead 27,804 tons, worth a total of $7,637,118.

A 400-ton electrically-driven plant is being constructed for Frank Wallower and associates on a 20-acre lease of the Connor land, south of Carterville. Sheet ore has been proved at a depth of from 185 to 205 ft.——A U. S. Bureau of Mines rescue-car is to be sent to Joplin for three weeks instruction.

MONTANA

Silverbow County

On the night of August 20, the head-frame, hoisting engine, engine-house, orebins and shaft collar of the Mountain View mine of the Anaconda company were destroyed by fire. The damage is estimated at $100,000. Work was suspended at this mine early in August.——The North Butte mine has been shut down temporarily.

NEVADA

Elko County

The Eastern Star mine in Gold Circle district, in the western part of the county, is to be equipped with a 50-ton amalgamating and cyaniding mill. A. D. Cox has been appointed mine manager, and is now engaged in conducting mill tests in San Francisco. The Company estimates 20,000 tons of ore in the mine and dumps, of an average value of $30 per ton, of which 10,000 tons is developed on three sides. The vein is from 5 to 15 ft. wide, and the ore-shoot is 140 ft. long. There are two quartz veins, on the foot-wall and hanging wall, which carry high gold content. The property is patented and has ample water for mine and mill purposes. R. S. Bolam, vice-president and director, has resigned, and was succeeded by C. F. Spilman, of San Francisco. The office of the Company is at Winnemucca. L. G. Campbell, of Winnemucca, is secretary and treasurer and resident agent.

The Nevada Copper Mining, Milling & Power Co., at Contact, is to erect a 100-ton leaching plant, the crushing department to have a capacity of 500 tons per 8 hours, so allowing for future increases. The process will be similar to the Butte-Duluth at Butte, Montana. Henry Smith is manager.

Humboldt County

The Seven Troughs Coalition gold yield in August will be about $26,000. In a raise above 1200 ft. there is 2 ft. of $624 ore; and in the south drift at this depth is 10 ft. of ore, with a streak assaying $481 per ton. The foot-wall streak of 24 in. is worth $99. Ore in the stope above 1150 ft. assays $243, and a stope north of the Bird winze above 1200 ft. is $198 per ton, according to L. A. Friedman, of the Company.

Lander County

A plant consisting of a rock-crusher, Denver quartz mill, and Isbell vanner is now treating the rich silver-lead ore of the Ruby silver mine, 12 miles from Battle Mountain, and in charge of George Abel. Another Denver mill has been ordered, and the capacity of the plant will be from 60 to 75 tons per day. The mine has been developed by adits. Charles Day is mine superintendent.

Nye County

Seven mines at Tonopah produced 11,026 tons of ore worth $207,800 last week.——The Belmont in July treated 14,984 tons of ore yielding 3079 oz. gold and 283,593 oz. silver, and a profit of $102,316.——The Extension's yield was 6002 tons for $110,091, with a profit of $51,120. A 150-hp. electric Nordberg hoist was ordered last week for the mine. Additions to the mill and surface plant are progressing well.——Profits of the Jim Butler in July amounted to $9395 from 3950 tons of ore.——According to Clyde A. Heller, the Belmont company has six months supply of cyanide and zinc-dust on hand, the other mines are well stocked, and all have good cash reserves to help their difficulties, if any, in the silver market.

OREGON

Josephine County

(Special Correspondence.)—The old Granite Hill mine, in the Louse Creek district, are to be reworked by the Oregon Gold Mines Co., in charge of J. M. O'Grady. The first work will be to unwater the mine by baling. Electric pumps were drowned on No. 7 level some time ago. There is said to be a good tonnage of ore developed, containing fair gold content. There is a good equipment consisting of a hoist, compressors, steam and electric power-plant, 30-stamp mill and concentrators, all in good order.——Several mines in Southern Oregon are backed by European capital. The Braden mine has been shut down since the war started, although making good returns. The Bill Nye is owned by French people, but is still working.

Grants Pass, August 12.

UTAH

On account of the improvement in the metal market, lead-zinc-silver mines of the state are resuming production.

Beaver County

Mining has been restarted at the Moscow silver-lead mine in the Star district, and ore shipments are to be made shortly. The new shaft is down 800 ft., and some ore was cut there. There are 63 men employed.

Carbon County

In driving an 8 by 12-ft. tunnel through hard rock in the Utah Fuel Co.'s Clear creek mines, a record was made of 360 ft. in 30 days, working two shifts per day. The tunnel is to be 1000 ft. long. Drills of 3¼ in. size were used to drill 6-ft. holes, and 60% gelatine broke the ground. Between $150,000 and $200,000 will be expended by the Company in the installation of new equipment to consist of an electric power-plant, transmission lines, tracks, electric locomotives, undercutting coal machines and various other forms of equipment necessary.

Juab County

The advance in the price of spelter has resulted in zinc ores being mined again in the Tintic district, especially from the 200, 300, 400, and 500-ft. levels of the May Day, and 1500, 1700, and 1800-ft. levels of the Lower Mammoth.——Eighty-four cars of ore were shipped from the district last week.

Salt Lake County

The Ohio Copper Co.'s coarse-crushing plant at Lark is now working.—Owing to the better outlook for silver, smelters in the district are paying 40c. per ounce for silver, instead of 25c. as heretofore, and silver producing mines are resuming full operation. Copper is paid for at 10c. per pound, and lead at $3.87½ per 100 pounds.

Summit County

Since the Daly-Judge property stopped producing ore, the main shaft is being repaired and retimbered to 200 ft. and the mine and mill equipment thoroughly overhauled. The improved price of silver may induce the Company to resume work, according to the general manager, G. W. Lambourne.

——Driving the Snake Creek tunnel is under full swing, 14 ft. per day being made, the total distance being 8600 feet.

WASHINGTON

The Republic Consolidated Mines Corporation, capitalized at 150,000 shares at $1, recently organized to take over the Lone Pine, Pearl, and Surprise mines at Republic, the properties of the defunct Republic Mines Corporation, has completed the details of its incorporation and taken charge of the mines. A. B. Willard, of Tekoa, is president of the new Company; J. P. Burson, of Tekoa, treasurer; A. J. Laughlin, of Spokane, secretary; and Forrest I. Gill, of Spokane. George S. Bailey, of Republic, who was federal trustee in bankruptcy for the bankrupt concern, is general manager. The new Company has taken a bond for $150,000 on the R. M. C. mines, and the first payment will amount to $54,500, cancellation of the claims of the secured creditors, which consist of a $32,000 mortgage held by A. B. Willard and A. J. Laughlin, a judgment held by F. C. Robertson for $2500, taxes amounting to $12,000, industrial insurance fees of $1000, and accrued interest on all. The remaining $95,500 is to be paid within two years. Royalties on ore shipments of 10% on $12 per ton or less, 15% on that running from $12 to $20 per ton, 20% on that between $20 and $25 per ton, and 30% on all over $25 per ton ore, are to be turned over to the trustees of the Republic Mines Corporation to pay the unsecured claims, approximately $35,000, which now have become secured by the cancellation of the preferred debts.

CANADA

Ontario

As the International Nickel Co. has its refinery in Wales, it has closed down all of its mines save the Creighton, and operations there have been considerably curtailed. The Alexo mine shipped 654 tons of ore in July.

MEXICO

Chihuahua

According to Karl Bernson, of the General Engineering Co. of Salt Lake City, which Company is to reconstruct El Rayo mill, the country is devastated and battle-torn. Stocks in stores of various towns are very low. There is a shortage of labor, Mexicans preferring the easy life of Villa's army to working about mines. It is said that Villa used to be head teamster for El Rayo Mining Co. Generally, the outlook for a revival of mining is fairly bright.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai province, reports the following results for July, 1914:

Stamps working	40
Time, days	28.75
Oré crushed, tons	6140
Total recovery	$68,500
Operating expenses	28,000
Net earnings	42,500

PHILIPPINE ISLANDS

Philippine Dredges, Ltd., boats in June recovered a total of 1027 oz. gold. No. 1 handled 12,600 cu. yd. averaging 34c. per yard; No. 2, 13,300 cu. yd. of 22c.; and No. 3, 27,000 cu. yd. of 46c. per yard. The lower tumbler of No. 1 caused 8 days' delay, the main pump on No. 2 lost 21 days, and on No. 3 the condenser and main engine crank-shaft required 9 days to repair. The pontoon of No. 4 dredge was launched on June 27. A typhoon caused further loss of time, resulting in only 52,900 cu. yd. for the three boats, against 127,750 in May.

PERSONAL

Philip Argall has been in Idaho.

Ralph Arnold was in San Francisco.

Hennen Jennings is at Camden, Maine.

J. H. Janeway, Jr., is in San Francisco.

R. A. Penrose, Jr., was in San Francisco.

Horace V. Winchell is expected at Butte.

Charles Janin left for New Mexico, Monday.

Ernest H. Simonds is at Melones, California.

William Brewer has been at Prince Rupert.

Granville Moore is in Alaska on examination work.

William S. Mann is testing the ores of La Trinidad Mines, Placer county, California.

Henry H. Armstead has returned to New York from Mexico, where he has been on a business trip for six weeks.

C. Colcock Jones has returned to Los Angeles after a month's absence in Arizona and southeastern California.

D. L. H. Forbes has accepted the position of chief construction engineer for the Chile Exploration Co., at Chuquicamata, Chile.

J. A. Holmes has much benefited in health from his stay in New Mexico, but does not expect to return to Washington for several months.

W. M. H. Woodward has been appointed mineral examiner of the U. S. Forest Service District No. 6, with headquarters at Portland, Oregon.

A. B. Emery has been appointed general manager for the Messina (Transvaal) Development Co., Ltd., and has gone to Messina to take charge.

A. J. Houle has been appointed professor of metallurgy and ore dressing at the Michigan College of Mines to succeed S. S. Bruce, recently resigned.

H. F. Lunt, of Colorado Springs, made an examination recently of the Scotia mine of the San Juan Queen group, situated in Picayune gulch, in the Animas Forks district.

Stanly A. Easton, manager for the Bunker Hill & Sullivan Mining & Concentrating Co., spoke on the mining industry of Idaho at the eleventh annual miners' picnic at Kellogg last week.

Lloyd B. Smith, of the Associated Geological Engineers, sailed on August 12 for Colombia, S. A., where he will be engaged in the examination of oil territory for a couple of months.

D. C. Jackling has removed his residence from the Hotel Utah at Salt Lake City, to the St. Francis Hotel, San Francisco; he has taken the top floor of the new Hobart building for his head office.

Solon Spiro, president and general manager for the Silver King Consolidated Mining Co., of Park City, Utah, is in Germany, and cablegrams have failed to reach him in either Switzerland or Germany.

James Bowe, for several years dredge-master of the Empire dredge, owned by the Oro Electric Corporation, at Oroville, has been appointed superintendent for the La Grange Dredging Co. at La Grange, California.

Among those planning to attend the Lake Superior field meeting of the American Association of State Geologists, August 27 to September 2, were E. A. Smith, Alabama; H. A. Buehler, Missouri; L. W. Trumbull, Wyoming; Joseph Hyde Pratt, North Carolina; J. A. Bownocker, Ohio; R. R. Hise, Pennsylvania; C. W. Shannon, Oklahoma; W. O. Hotchkiss, Wisconsin; I. C. White, West Virginia; W. H. Emmons, Minnesota; F. W. DeWolf, Illinois; E. H. Sellards, Florida; George H. Perkins, Vermont; R. C. Allen, Michigan; E. O. Ulrich, United States Geological Survey; W. G. Miller, provincial geologist, Ontario.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, August 27.

Antimony	No quotes
Electrolytic copper	15¼
Pig lead	3.90
Quicksilver (flask)	$80.00
Tin	No quotes
Spelter	7¾
Zinc dust, 100-kg. zinc-lined cases	15

Although the above prices are given, there has been little business done, and in the case of quicksilver and zinc dust stocks are small. According to the U. S. Geological Survey, antimony during the past six years has ranged from 7.15 to 10.31c. per lb., and in July about 7.05c., but since the war it has risen to over 20c. per lb. The United States annual consumption is 12,755 short tons, of which 7440 tons is imported. Deposits of this ore in this country can now be profitably worked.

EASTERN METAL MARKET

(By wire from New York.)

New York, August 27.—Lead is quiet at 3.87c.; spelter, 5.77c., with little domestic inquiry, but considerable export demand; while copper is unchanged. The McKinley-Darragh, of Cobalt, declared its regular quarterly dividend of 3%. Exports of gold and silver from New York for the year up to August 15 were $126,962,949 and $25,692,576, respectively, against $68,742,696 and $31,551,899 for the same period of 1913. Platinum is over $50 per ounce. The European market for radium-bearing ores is entirely closed.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 20	No quotes	July 15	55.60

June	59.03	56.43	Dec.	57.73	....

The Smoot bill authorizing the Secretary of the Treasury to buy 15,000,000 oz. of silver from American mines within six months passed the Senate on August 23 by 39 to 11 votes. The measure is now before the House. This should make a regular market for about 25% of the annual production of the country. The San Francisco Mint is now a buyer for 200,000 oz. of the metal. On August 27 there were quotes at 58⅝c. per oz. Smelters at Salt Lake City are now advancing 40c. per oz. on ore shipments. The French mint is coining silver night and day. Bar silver in London was 25d. (50c.) on August 26. Advice from London of August 13 states that the average for that week was 26.75d. for cash transactions. Stocks there early in the month were about 5,000,000 oz. On the whole, the silver market is fairly satisfactory.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per pound more. Prices are in cents per pound.

Date.		Average week ending

June	14.71	13.60	Dec.	14.25	....

Exports during the third week of the month were 5084 tons, an increase of 2927 tons, the month to date showing a decrease of 13,723 tons, and the year to date an increase of 26,221 tons. Smelters in Utah are advancing 10c. per lb. for the metal. Our New York letter of this issue covers the copper situation.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

June	5.00	4.84	Dec.	5.07	....

The St. Louis market is higher at 5.87c. per pound

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July 23	37.50	Aug. 13	85.00
" 30	37.50	" 20	No quotes
		" 27	80.00

TIN

As soon as vessels are available, tin should be coming to the United States. Bolivian concentrate can be smelted at Bayonne, New York. There is 920 tons of metal afloat for this country, and 2115 tons have arrived since August 1. Prices have receded and are now down to 43c. per lb. A feature of the market is the irregularity and declining tendency of the spot price. Tin-plate works have curtailed their output, and tin plate has advanced in price. A revival of the Welsh tin-plate business is starting.

CYANIDE

Advice from New York states that Roessler & Hasslacher have called in all their salesmen, having the next two years' business in sight. The firm does not consider the shortage serious, and thinks there is enough for all if consumers are careful. Prices are unchanged. The Rand used 10,167,934 lb. in 1913, of which half came from Germany. The present supply in Africa is about three months. A higher price should stimulate production from gas works' by-products.

The Zinc Situation

By C. E. SIEBENTHAL

Supplementing its midyear statistics of spelter production, published in the *Press* of August 22, the U. S. Geological Survey makes the following statement on the general zinc situation, especially as affected by the war in Europe.

By a queer coincidence the great smelting centres of continental Europe are in regions where active fighting is now going on or may be expected in the near future. The zinc smelters of Upper Silesia are in the extreme southeastern portion of Prussia, mostly in the Kattowitz, Beuthen, and Tarnowitz districts, which are adjacent to one another and lie within five or ten miles of the Polish-Russian border and near the corner of Russia, Austria, and Germany. The two smelters in Russian Poland are just across the border from the Silesian smelters. They all seem destined soon to be compelled to suspend, or decrease operations on account of military activities, and in any event their output certainly cannot reach the outside world. The same thing is true of the smelters in Rhenish Prussia and Westphalia, some of which are very near and most of which are within 100 miles of Liége. In Belgium all but three or four of the zinc-smelting plants lie between Verviers and Liége or are strung along the valleys of the Meuse between Liége and Namur, and their industrial prospects can well be imagined. The zinc smelters of France lie outside of the territory where active military operations are likely, and so will probably suffer only from scarcity of labor as the employees are called to the colors, and from derangements of transportation. The same is true of the zinc smelters in England, but those of Austria-Hungary will, of course, be put out of commission. Other small smelters in Europe, Australia, and Japan will possibly not be affected except as transportation is interrupted. From these observations it can be seen that the zinc-smelting industry of Europe will be in a sadly demoralized condition while the war continues and for some time thereafter.

The following table shows the number of smelters in each European country in 1910, the latest year for which information is available, the production for that year, and also, for comparison, the production for 1913, in short tons:

	No. of plants.	Production, 1910.	Production, 1913.
Germany:			
Upper Silesia	24	154,596	187,522
Southwest Germany	10	96,450	102,350
Belgium	13	190,233	217,928
Great Britain	17	69,531	65,197
France	5	57,805	78,289
Spain	2	7,206	
Holland	1	23,121	26,811
Austria-Hungary	4	14,666	23,928
Norway	1	.....	10,237
Russian Poland	2	9,514	8,389
Total	..	.....	720,651

The output of the smelters in Australia and Japan in 1913 was 11,395 short tons.

If the war continues for one year, the output of these countries for that period would, at a conservative estimate, be only about 250,000 tons—a loss of nearly 500,000 tons for the year. The continental spelter market will also be demoralized, however, so it may be that the reduced production will still be ample. Apparently England's industrial activities after the first readjustments are over may not be seriously restricted.

The war but serves to emphasize a condition which already confronted the zinc industry of the United States. The zinc-smelting capacity of this country has been increasing of late years all out of proportion to the consumption, as the following table will show:

Year.	Retorts at close of year. Number.	Est. max. an. capacity, short tons.	Production, short tons.	Appar. consumption, short tons.
1908	93,958	404,960	210,424	214,167
1909	94,328	400,681	255,760	270,739
1910	93,722	398,105	269,184	215,884
1911	85,018	361,327	286,526	280,059
1912	107,948	458,779	338,806	340,341
1913	113,786	483,591	346,676	295,370
1914	130,274	561,165	*175,058	*149,363

*For first six months of year.

The actual gain in capacity is even more than is indicated in the table, for in the earlier years a number of small, antiquated smelters that had been idle for several years were included in estimating the total capacity, whereas in the later years almost all such smelters have been dismantled or abandoned completely, and there have been more new modern additions than ever before in the same time. It is to be borne in mind that a certain portion of the capacity is taken up in the redistillation of zinc drosses, and that some plants do not yield full capacity because they treat lower-grade ores, so that the spelter produced from ore always falls several thousand tons short of the maximum capacity. On the other hand, the new zinc oxide plant at Leadville, Colorado, will take a great deal of the low-grade carbonate ore away from the zinc smelters, so that the capacity per retort will be increased because of the higher grade of the remaining supply; and the introduction of ore flotation in the Western States will probably raise the grade of zinc concentrate from that area, likewise increasing the capacity per retort.

The following table shows that the production of zinc at the mines is increasing. Figures are in short tons:

	1912.	1913.
Joplin district	152,465	146,474
New Jersey	69,755	84,122
Colorado	66,111	59,673
Montana	13,459	44,337
Upper Mississippi Valley	37,115	32,346
Other states	39,911	51,430
Total	378,816	418,382

The largest increase in sight comes as a result of the application of ore flotation concentration in Montana, but an increase due to the same cause is to be looked for in Idaho and possibly in Utah. In Montana the Butte & Superior mill is now producing at the rate of 50,000 tons of zinc per year, and the new Pilot-Butte mill, which has just gone into operation, should raise the state output to 70,000 tons per year, or if, as planned, another unit is added to this mill the state output may rise to 90,000 tons and more by 1915. In Colorado the new zinc oxide plant at Leadville is reported to be purchasing 14% zinc carbonate ore, as against a minimum of about 20% ore purchased by zinc smelters. As the Leadville carbonate ore is not amenable to concentration, this means a large increase in the available zinc ore resources of that region. Another source of zinc which will be made available in the future is zinc-bearing copper ore, the zinc content of which at present either makes the ore unsalable or, when the ore is smelted for the copper, collects as flue and bag-house dusts, for the recovery of the zinc from which there is at present no suitable process. Much ore of this sort is mined in Shasta county, California, and such zinciferous dusts are accumulating in large quantities at the smelters in that region.

With the establishment of peaceful conditions in Mexico, it is to be expected that imports of zinc ore from that country will again reach large proportions, and likewise the imports

from Canada may perhaps become larger even than they were in 1909, before the imposition of the tariff. With the closure of the Belgian and other continental markets to the zinc concentrate from Broken Hill, Australia, this product may be partly diverted to the United States. If a sufficient foreign market becomes available, the surplus smelter capacity in the United States might perhaps be employed in smelting foreign zinc ores under bond, and a business might grow up similar to that which exists in lead smelting. This work could be done only at the expense of domestic production of zinc ore, for the present domestic production more than equals the apparent domestic consumption as spelter and as zinc oxide and bids fair to exceed it greatly in a year or two unless consumption is increased by development of export trade in manufactured zinc and galvanized-iron products.

The opening of the Panama canal, the necessary establishment of American lines of transportation to South America, Australia, and the Orient, and, in the present crisis, the large dependence of those continents on the United States for their supply of zinc, all make for a quick commercial introduction of the products of the United States zinc industry to those continents—an introduction which under other conditions might have taken years.

It is known that large stocks of spelter exist in Europe. The *Ironmonger*, of London, gives the stocks at the end of March as 73,000 long tons and quotes an estimate of 80,000 long tons for the end of April. At that rate the stocks on hand June 30 must have been considerably over 100,000 short tons, compared to 64,039 short tons in the United States. The greater part of the European stocks, however, must have been held in the interior and must now be isolated, so that for the term of the war they may be disregarded. After the war what remains of these stocks will become available again and will possibly operate to depress prices, but in the meantime the United States zinc operators will have had the opportunity to dispose of domestic stocks and to become established in the foreign markets.

There is a foreign market for over 72,000 tons of zinc, of which about 30,000 tons consists of spelter in slabs and the remainder of zinc sheets. The American zinc industry should stand an excellent chance to take over the trade in zinc slabs and such part of the trade in zinc sheets as American zinc-rolling mills can furnish. The trade in galvanized-iron sheets is dominated by Great Britain, which controls 87% of the total export trade in that commodity with the four countries concerned. In addition to over 65,000 tons of spelter smelted in her own plants, Great Britain in 1913 imported 150,000 tons, presumably used chiefly in making her enormous output of galvanized iron. It would seem that any expansion in Great Britain's foreign trade either in spelter and zinc sheets or in galvanized iron would entail the importation of more spelter from the United States. This country has the opportunity, therefore, to furnish the major part of 222,000 tons of spelter a year as long as the war lasts, together with whatever part of the spelter for the galvanized-iron trade of the southern continents and Asia it can acquire. By the time the war closes, American zinc should have obtained a permanent foothold in these markets, sufficient to take care of the surplus smelter capacity of the United States.

These calculations do not take into account the increased exports of zinc pigments that must come about, thus absorbing some of the domestic surplus zinc resources. Moreover, the United States imports each year from Continental Europe about 2500 tons of zinc dust. This supply of zinc dust is now cut off, and the dust has already greatly advanced in price. Zinc dust is produced at two American smelters and could easily be produced at others, so that no doubt the better prices will result in the whole demand being supplied from domestic sources, thus absorbing another portion of the surplus zinc ore.

BOOK REVIEWS

TWENTY-FOURTH ANNUAL REPORT of the Transvaal Chamber of Mines. P. 603. The Argus Printing & Publishing Co., Ltd., Johannesburg, 1914.

The Transvaal Chamber of Mines is an influential body and represents 76 of the most important mining companies in South Africa. A glance at the report for 1913 shows the area and extent of the mines and various other important details. These mines produce about 40% of the world's gold, which was approximately £93,416,000 in 1913, £37,358,000 coming from the Transvaal from 26,267,840 tons of ore. Since 1884 this state of the Union of South Africa has produced gold worth £401,138,233. Dividends paid in 1913 amounted to £8,596,532, and £100,059,305 to date. During the fiscal year ended March 31, 1913, the Union government received £2,359,263 in taxes from all mines, of which £1,011,429 was from gold mines. An average of 24,015 white and 195,614 colored persons were employed in the Transvaal in 1913, who drew a total of £13,476,300 in wages. There were 65 white and 668 colored workers killed, giving a death rate of 3.02 and 3.74 per 1000, respectively. Stores purchased during the year totaled £10,579,712. Such figures indicate the magnitude of the industry. The annual report also gives information on the Chamber's constitution, report of the annual meeting, balance sheet (income of £18,581), president's address, all particulars of native labor, legislation affecting mining, mine sanitation, analysis of gold production and dividends, statements presented to the Economic Commission (a British commission investigating resources, etc., of the colonies) of 182 pages, a list of companies registered in the Transvaal in 1913 with a total capital of £10,253,258, and a list of liquidations of companies with a total capital of £8,104,710.

HANDBOOK OF MILLING DETAILS. Compiled from the *Engineering and Mining Journal* by the Editorial Staff. P. 125. Ill., charts, index. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price, $1.

This may be called a companion work to the 'Handbook of Mining Details,' published by the same firm in 1912, and is in every way as useful for millmen as the other was for miners. The book is a collection of articles which have been published in the New York journal during the last two or three years under the general head of 'Details of Metallurgical Practice,' and were written by a large number of operators working under widely different conditions. As is highly desirable in all such compilations, this one has been arranged with definite departments as follows: sampling; ore dressing—breaking, crushing, and grinding; ore dressing—washing, separating, and concentrating; accessory apparatus for ore dressing; notes on the equipment of metallurgical plants; hydrometallurgical processes; smelting; and refining. Practically all apparatus described is illustrated. Credit must be given to John Tyssowski for the arrangement and revision of a large part of this useful book.

RECOMMENDATION AS TO SANITATION CONCERNING EMPLOYEES OF THE MINES OF THE RAND. By W. C. Gorgas. P. 21. Argus Printing & Publishing Co., Ltd., Johannesburg, 1914.

This is the report made by the well known sanitary expert of the Canal Zone to the Transvaal Chamber of Mines, and was reviewed in the *Press* of August 1.

GENESIS OF THE MACKAY COPPER DEPOSITS, IDAHO. By Joseph B. Umpleby. Reprint from *Economic Geology*. P. 52. Illustrated. An abstract of this paper was published in the *Press* of July 11.

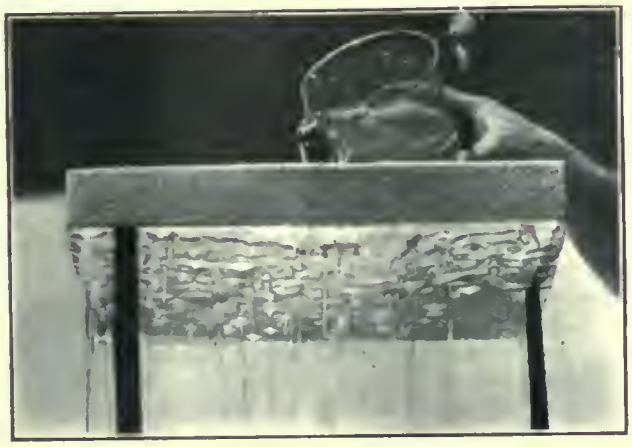
New Machines and Devices

The New Porous Mineral Medium

A few years ago metallurgists and especially those interested in cyanidation, were offered an agitation and filtration medium in the form of a porous tile which was placed on the market by the Just Process Co. While results with this medium were successful in a number of instances, its continued use resulted in mechanical difficulties, non-uniformity, and weakness in structure, which greatly depreciated its original value. This so-called 'silica sponge' tile was produced by mixing the clay with an organic material which was burned out in the manufacture of this product, and instead of the much sought after uniformity in texture and porosity, a tile having considerable dead or closed cellular space resulted; also, it being of clay material with high per cent of alumina, did not resist acids and many chemical solutions. J. E. Porter, of Syracuse, New York, who was one of the inventors of the Just tile, upon its weakness becoming apparent, set about to eliminate these objectionable characteristics, and after a great amount of patient research has developed the new porous mineral medium 'Filtros.' Broad claims have been allowed on the Porter inventions which have been assigned to the General Filtration Co., Inc., which Company has also acquired patents covering the use of a porous mineral septum in a number of industrial arts.

The principle of this new material is similar in theory to the Just tile, but the new product possesses a number of features which are completely lacking in the Just tile. 'Filtros' is of particular interest on account of its resistance to acids, chemical solutions, and high temperatures, and its physical strength and uniformity of porosity. This new development makes possible the production of a truly porous silica septum; no clay nor organic matter being used in its manufacture, it is resistant to chemicals and is free from dead cell space, giving it properties not possessed by other porous mineral materials. 'Filtros' is a white porous ware composed almost entirely of silica. Its excellent physical strength and hardness enable it to resist the mechanical stress and abrasion accompanying many of the metallurgical processes. The uniformity in porosity of 'Filtros,' claimed by the manufacturers, may well be advanced for its adaptability to problems involving aeration and agitation, and the refractory property of the product suggests its application to smelter practice. Its indestructibility indicates the economies possible in its substitution for canvas and muslin in various metallurgical problems.

The following figures are the results of air-rating tests and serve to illustrate the degree of porosity and uniformity of 'Filtros' tile. These show the number of cubic feet of air passed per square foot area of the standard tile $1\frac{1}{2}$ inches in thickness per minute at the given pressure.



'FILTROS' TILE, SHOWING POSSIBILITIES IN FILTRATION AND AGITATION.

Specimen.	Cu. ft. of air at 2-inch water pressure.	Cu. ft. of air at 4-inch water pressure.
1	13.0	25.0
2	12.5	24.5
3	12.0	23.5
4	12.0	24.1
5	12.5	24.0

From a large number of immersion tests the following results bear evidence of the resistance of 'Filtros' to various chemicals:

Solution.	Strength.	Time immersed.	Temperature.	Loss, per cent.	Condition.
Sulphuric acid....	96%	24 hrs.	200°F.	0.020	unchanged
Sulphuric acid....	96%	8 days	"	0.023	"
Hydrochloric, $\frac{2}{3}$ of	70%				
Nitric, $\frac{1}{3}$ of	37%	24 hrs.	"	0.017	"
Nitric	35%	8 days	"	0.016	"
Water, distilled...		35 "	"	0.000	"
Sulphuric acid....	20%	35 "	"	0.110	"
Hydrochloric	20%	35 "	"	0.140	"
Nitric	20%	35 "	"	0.080	"
Zinc sulphate.....	sat. sol.	20 "	"	0.040	"
Potassium cyanide	50%	20 "	"	0.090	"
Mercury bichloride	sat. sol.	8 "	"	0.021	"

Other tests show 'Filtros' to be resistant to ordinary chemi-

icals as well. Hot or concentrated strong alkalies affect 'Filtros' as it does other silica wares. In testing the tile for use in filtering, the bicarbonate sludge from the carbonating towers in the ammonia works (Solvay Process) practically no action is shown on the tile. As far as the action of zinc sulphate on the tile in the manufacture of lithophone where barium sulphite is filtered from zinc sulphate is concerned, 'Filtros' is admirably suitable. Potassium cyanide does not affect 'Filtros" which fact indicates its applicability in the cyanidation of ores for aerating, agitating, and filtering. The standard tile are 12 by 12 by 1½ in., and show a porosity of 40% by void. A variety of special shapes may be made for exceptional cases. Tile of various grades of porosity are possible which are capable of retaining from the finest to the coarsest solids with maximum efficiency in filtration. Many uses for a mineral septum having the distinguishing properties of 'Filtros' will suggest themselves to engineers interested in such problems as gas and liquid filtrations, agitations, and aerations, and processes employing a porous diaphragm.

Indication of the remarkably free flow of liquids through the tile is shown in the following table, which gives the amount of water filtered per square foot area of the standard tile 1½ inches in thickness under the given head pressure:

Head pressure.	Gallons per minute per sq. ft. area.	Temperature of water, F.°
5	1.40	50
10	2.15	50
15	2.61	50
20	3.27	57
25	3.42	57

The Company concludes from the results of the tests given here, as well as many others, that the tile may be safely used for filtering acids of all strengths and solutions of salts, but not for the concentrated stronger alkalies. The tile are apparently adapted to copper leaching processes, sulphuric acid filtration, as well as various chemical and metallurgical processes. The accompanying halftones illustrate the porosity of the tile for filtration, agitation, and aeration purposes.

Commercial Paragraphs

The *Du Pont Magazine* for August contains an interesting discussion of 'The Care and Operation of Blasting Machines.'

Western Electric Co., New York, has for distribution an attractive publication entitled 'Modern Methods in Train Dispatching' and railway telephone equipment.

National Tube Co., Pittsburgh, Pennsylvania, in National Bulletin No. 10-C, presents an interesting paper by William H. Walker entitled 'The Relative Corrosion of Iron and Steel Pipe as Found in Service,' with discussion of the subject by F. N. Speller.

The Hess Flume Co., Denver, Colorado, has recently issued Catalog 214, which is devoted to flume construction and equipment. The catalog is replete with diagrams, halftones, and data regarding the construction and operation of Hess flumes for power, mining, and irrigation purposes.

The Hayward Co., New York City, Pamphlet No. 603 on clam-shell buckets. The electric motor clam-shell bucket is said to dig as much or as little of its rated capacity as desired and the load may be discharged gradually, avoiding injury to cars or hoppers. Pamphlet is fully illustrated.

Allis-Chalmers Manufacturing Co., Milwaukee, Wisconsin, has recently issued Bulletin No. 1087, devoted to polyphase induction motors. Features which are claimed for this type of motor in general service are: simplicity, built for severe service, low maintenance cost, sparkless operation, and reliability. Bulletin No. 1722, devoted to carriage feeds, and Bulletin No. 1085, descriptive of kerosene engine-generating sets, are also new Allis-Chalmers publications.

Chicago Pneumatic Tool Co., Fisher building, Chicago, Illinois, has issued Bulletin No. 34-W, which discusses class A-O 'Giant' fuel oil engines. These engines have no valves, gears, carburetors, mixers, oil, or air heaters, magnetos, timers, wires, or spark plugs. Details of construction are presented with halftones.

The Denver Quartz Mill & Crusher Co., of Denver, Colorado, reports the sale of a 500-ton Denver steel ore-crusher to the Blair-Athol M. & M. Co. of Colorado Springs, Colorado, and a 50-ton Denver quartz mill to the Ruby Silver Mining & Development Co. of Battle Mountain, Nevada. This is the second Denver quartz mill purchased by this Company.

Stevens-Adamson Mfg. Co., Aurora, Illinois, has recently had published section 4 of 'S-A' General Catalog No. 19, which is devoted to elevating and conveying machinery, screw conveyors, flight conveyors, bucket elevators, gravity discharge conveyors, pivoted bucket carriers, and other equipment. The catalog is fully illustrated and contains complete details regarding the construction of these machines.

The Westinghouse Electric & Mfg. Co. reports the receipt of the following orders for mine apparatus: Anaconda Copper Mining Co., Butte, Mont., eight 150-hp. motors for driving mine pumps, each complete with an automatic starter, panel, and transformers. The Boston & Montana Reduction Works, Great Falls, Mont., has ordered two 8-ton barsteel locomotives. These locomotives are of particularly heavy construction, as they will be used for 'bunting' charging cars about the smelter. There is also being shipped to the Lochray coal department, Great Falls, Mont., one 75-kw. motor-generator set and switchboard. Daly West Mining Co., Park City, Utah, one 175-hp., 16-pole motor with magnet switch hoist control. This is the first Westinghouse magnet switch hoist control to be installed in Utah. Also one 400-hp., 150 r.p.m., synchronous motor for driving a Laidlaw-Dunn-Gordon air-compressor. Utah Copper Co., four 10-hp. special vertical motors for driving agitators for oil flotation, and six 1-kw. turbo-generator units, which will be used for supplying light to steam-shovels operating in the copper mine. The turbines are bolted direct to the shovel frame and supplied with steam from the shovel boiler. Yukon Gold Co., Iditarod, Alaska, six 125-kva., oil-insulated, self-cooled transformers. Jualin Alaska Mines Co., Jualin, Alaska, one 100-kva. water-wheel generator; three 25-kva. transformers; one 75-hp. motor, and one 2-panel switchboard. Kennecott Mines Co., Kennecott, Alaska, one 75-hp. special motor with magnet brake and automatic control. Alaska Treadwell Gold Mining Co., Treadwell, Alaska, one 4½-ton storage-battery locomotive, one 8-ton barsteel trolley locomotive, and one No. 354 200-hp., 2200-volt motor with magnet switch control for automatic acceleration, which is the largest electric hoist motor in Alaska and the first magnetic switch control ever installed there. Kennecott Mines Co., Kennecott, Alaska, one 500-kva. turbo-generator unit, and one 2-panel switchboard. Beatson Copper Co., Latouche, Alaska, two 625-kva. turbo-generator units, one 6-panel switchboard, and two 16-kw. motor-generator exciter sets. Tonopah Merger Mining Co., Tonopah, Nevada, one 250-hp., 200 r.p.m., synchronous motor with switchboard panel and motor-generator set for driving Sullivan Machinery Co. compressor. Tonopah Belmont Development Co., Tonopah, Nevada, one 125-hp. motor for direct connection to Nordberg mine hoist, and one 75-hp. motor for direct connection to Aldrich pump. Burro Mountain Copper Co., Burro, N. M., four 300-kva. and six 100-kva. and three 37½-kva. oil-insulated, self-cooled transformers, for a new copper property being developed by the Phelps-Dodge company. United Verde Copper Co., Jerome, Ariz., three 300-kva. and three 30-kva. oil-insulated, self-cooled transformers for a new smelter at Clarkdale, Arizona.

POWDERED coal is to replace oil in the reverberatory furnaces at Garfield, Utah, the experiments that have been under way there for some months, having proved sufficiently successful to warrant the change.

THE MONEY situation in Mexico presents an interesting problem for the Carranza administration to unravel. In addition to the bales of paper currency bearing the stamp of the Constitutionalists, there are the millions of worthless Federal paper, the I.O.U's of the various rebel leaders, and the private issues of mining companies and other corporations.

POTASH salts are among those likely to be brought into sharp demand as a result of the war in Europe. Germany has now a practical monopoly of the potash business, though the American Trona Corporation hopes to care for a part, at least, of the American demand within a few months. Mulhausen, around which fighting has been raging, is one of the German centres of potash production.

OUR little brown brothers in the Philippine Islands can perceive a useful object lesson in the present situation of Belgium, a country of which the neutrality had been guaranteed by all the most powerful nations of Europe, yet her cities and fields have been laid waste, while the invading army demands a war 'contribution' of $40,000,000. If the neutrality of the Philippine Islands were guaranteed by the United States the first great war in the Pacific would inevitably see Manila made a military and naval base by one or the other of the contending powers.

CHANGES in the smelting situation in Japan are presaged by the action of the Sumitoma company in purchasing a gold mine producing silicious ores, near Sendai, north of Tokyo. This ore is to be mixed with the basic Besshi ore, and the Shisaka smelter is to undertake general custom work. Previously smelters in Japan have been connected with individual mines or the mines of particular companies and there has been no general business in the purchasing and mixing of ores such as is conducted by the American Smelting & Refining and other great companies in North America. This change, by making a freer market and making easy the development of smaller mines, will undoubtedly stimulate mining in Japan.

MINE operators facing a shortage of cyanide might well try flotation. There are many ores with which the choice between the two methods of treatment is wholly a matter of cost, and under present conditions it may be profitable to change to flotation where ordinarily cyanide would be more economical.

RECEIVERS have been appointed for the International Steam Pump Company, though it is stated that the business of the concern this year has been within 15 per cent of its highest record. The difficulty is due to the necessity for raising cash to meet interest and sinking fund payments aggregating $485,000, September 1. There will be no interference with the business of the constituent companies.

A CURIOUS feature of the investments of many prominent financiers, disclosed on their deaths, is that their holdings of mining stocks nearly always prove to be securities of unsuccessful corporations. It might be supposed that such well informed investors would buy only the best securities, but as far as mining is concerned, this seems not to be the case. This was shown in the appraisal of the estates of E. H. Harriman and J. P. Morgan, for example, and a more recent case is the estate of Anson Phelps Stokes, who left to his heirs only $250,000, instead of the millions he was popularly credited with. Mining is a highly specialized business, in which the chances of success by the amateur are less than is generally believed.

THE valor of ignorance is a factor to be constantly regarded and nowhere does it show more frequently than in the brave recommendations of amateur mining experts. We were shown recently a report upon a Calaveras county gold property in which the 'expert' after gravely announcing that "one of the most notable conditions is in the leaves and lenses of primary and secondary enrichment, branching out in natural laws, proving conclusively the origin of the orebodies together with their chemical and physical conditions as we find them today," recommended "that the supervision of the development and all other operations on the ground be retained only by a man of known ability, integrity, and industry—one who is thoroughly familiar with all the requirements and details of business." The advice is most excellent, but why stop at this? It would be better to begin by having the examination made by some thor-

oughly familiar with all the requirements and details." We were told this week of a placer examination recently made by an 'expert' at Grass Valley where his samples were salted by jokers with metallic copper and brass. He accounted for them by an absurd story of "volcanic spats." The best way to make money in mining is not to go into a venture relying upon an ignorant guide.

POSSIBILITY of transfer of the work of the United States Bureau of Mines as regards safety, to a new Bureau of Labor Safety has aroused wide protest and has been already discussed. We are glad to announce that the proponent of the bill, Mr. Shiveley, has agreed to an amendment substantially along the lines we suggested, leaving the work in the hands of the Bureau of Mines. Another and even more unsatisfactory proposal has since been made in the House where Mr. John J. Casey of Wilkes Barre, Pennsylvania, has introduced a bill to transfer the whole Bureau of Mines to the Department of Labor. The objections we urged to the transfer of part of the work apply equally to the transfer of the whole Bureau of Mines.

COERCIVE tactics of the Butte Mine Workers Union has resulted in most deplorable conditions in the Butte district and grave results are anticipated unless sane leadership supersedes the present dictatorial attitude of the new union. Shortly after the Western Federation of Miners sent out a statement to all unions of the Federation that men leaving Butte and not bearing a paid-up card in the Butte Miners' Union No. 1 were enemies to organized labor, the Butte Mine Workers issued a proclamation that all miners in the Butte district must have cards and wear the buttons of the new organization. Following this proclamation measures were taken to enforce it by large 'committees' calling at the mines as the workmen went underground and not permitting men without the insignia of the new organization to go to work. To avoid trouble several properties, which have been working regardless of the present state of the copper market, have suspended operations and the work of mining has been further curtailed. The dynamiting of the employment office of the Anaconda Mining Company and other atrocities has made necessary a call for troops and 600 state troops are now in Butte for the purpose of restoring order, with a battalion of federal soldiers at Fort William Henry Harrison near Helena for use at Butte if their services are needed. While it has been repeatedly reported that the new union would resist to the utmost any armed intervention on the part of the government, it is gratifying to note that the presence of soldiers has not been the signal for general rioting. The new organization seems to be no better than the old, and the present state of the copper market would not seem to be propitious to the carrying through of its coercive tactics. Copper companies have been taking great risks to keep their mines open in part and to give employment at least to the married men, but in view of the situation at Butte it would not be surprising if the Anaconda should simply close entirely and stay closed until free from union dictation. That policy will win and the Company is strong enough to put it in operation if it be thought desirable. Anaconda officials, many of whom came up from the ranks, have been wonderfully patient with the unions. We wonder when they will stop.

SUCCESSFUL operation of a mine under difficult conditions, and most mining is done under difficult conditions, calls for the fullest exercise of all the powers of a broad-gage man. The following quotation from the report of the manager of a well known mine in Mexico, for last year, indicates some of the incidental difficulties which frequently absorb much of the energies of the management of any remote mine. A superintendent who has to devote his energies to the local manufacture of ordinary necessities can scarcely be expected to make records in low costs and operating profit. It is underestimation of difficulties such as these that so commonly leads to the cost of development of remote properties exceeding the estimates. His comment follows: "It did not seem possible that conditions in northern Mexico could grow much worse than they were in 1912. During that year the procuring and transporting of supplies from the outside, while attended with much delay and trouble, was, nevertheless, always accomplished, but for the past ten months all transportation into the mountains has been abandoned. Owing to the threatening situation a year ago, I purchased supplies for the mine sufficient for six months' operations. Even at that time there was a great scarcity of mules and nearly two months was required for the delivery of the goods at the mine. Since the exhaustion of these supplies the scanty resources of that immediate region have been drawn upon for the bare necessities; such articles as soap and candles have been manufactured on the ground by the superintendent, and powder, fuse, and caps have been secured from a neighboring mine which, fortunately for us, closed down last spring with a considerable quantity of explosives on hand. Of all the mines in the western part of this state, ours is the only one which has not been forced to close down entirely during the past twelve months. Labor conditions here have always been unsatisfactory. During the construction of the plant I brought in at one time one hundred men with their families; we managed to retain ten or fifteen of them, the others all drifted back after the first payday. Later on I had an American take twenty-five men with their families from the city of Chihuahua, where, at that time, there was absolutely no work at any price. Notwithstanding the fact that I had the trails around the mine guarded to prevent their escape, they all left within a month, and most of them deserted us after the first full meal. Again I sent an American about one hundred miles north and he gathered between twenty and thirty men with their families; he reached the mine with about fifteen, and they did not remain long."

THE CALUMET & HECLA LEACHING PROCESS

In our issue of November 22, 1913, we published an account of the dredge which is to be employed by the Calumet & Hecla Mining Co. to reclaim its tailing from the bed of Lake Linden. This old tailing, after passing through the usual pipe-line supported on pontoons, will discharge at a point on the shore of the lake near the regrinding plant, where a second set of suction pumps will pick it up and raise it to a set of classifying and dewatering tanks. The sand will discharge through the bottom spigots and pass over a set of dewatering screens, discharging on a belt-conveyor which elevates it to the storage bins of the regrinding plant. The slime will flow directly to a set of Wilfley tables.

The principal purpose of the arrangement described is to allow flexibility, so that irregularities in the operation of the dredge will not affect the operation of the mill. When the main dredge is stopped the second set of pumps can continue to draw from the pond in front of them, and this, together with the mill-bins, will permit the mill to continue operating for a whole day. Another important feature is the possibility of operating in the winter time, when the surface of the lake is covered with thick ice. During this period the main dredge will be brought in near the dewatering plant, where the tailing has filled in the lake considerably above the water-level. Here the dredge will dig in a small pond, much as a gold dredge does. The amount of water involved will thus be limited, and as it will be warmed somewhat by the mechanical work done on it in pumping, it is hoped to be able to continue operations even in the middle of winter. The main dredge has a capacity much greater than the rest of the plant, and during the summer, when it works under the most favorable conditions, a portion of the sand pumped will be diverted to fill the excavation made during the winter.

The sand will be ground in 64 Hardinge mills, the grinding practice differing considerably from that in other mills. The pulp fed to the mill will consist of three parts of water to one of solids. No classifier is used on the discharge, only 35 tons per day being put through a 20-inch by 8-foot Hardinge mill, driven by a 40-horsepower motor. The reason for this is that coarse particles of copper liberated in regrinding would be returned to the mill by a classifier, and it is this grinding away of the free copper which it is desired to avoid. The ground pulp will pass over a series of Wilfley tables to take out the free copper.

The tailing from the Wilfley tables will still contain about one-half the copper present in the sand, and it is proposed to recover this by leaching, using a process devised by Mr. C. H. Benedict, the mill metallurgist, who has also worked out the plans for the whole scheme. Since no official statement in regard to this has been given out, there has been much speculation regarding the supposed secret process. There is, however, no secret regarding the matter, except certain details which are now undergoing patent, as the general chemistry of the process is well known. Acids cannot be employed on the pulp, as it contains too much calcium carbonate, so the well known reaction between ammonia and copper oxide will be utilized as the basis for the process. Finely divided copper has at all times on its surface a microscopic film of oxide of copper. If this is subjected to the action of ammonia in the presence of an ammonium salt, such as ammonium carbonate, the film of oxide is dissolved, going into solution as a double cuprammonium salt. If oxygen is present in the solution, the film of oxide is at once renewed and the process is a continuous one until all the copper has gone into solution. This reaction was first employed by Schnabel, many years ago, and was later used in gas analysis by Hempel for the determination of oxygen. Mr. Charles Van Brunt has recently described the use of this reaction for absorbing oxygen from the air in order to generate nitrogen. In his 'Handbook of Metallurgy,' Schnabel discusses its application to the hydrometallurgy of copper in these words: "Experiments hitherto tried along these lines have failed because ammonia-tight vessels were not employed, and because the precipitation of the copper, for which iron cannot be employed, was performed by means of H_2S, CaS, or BaS. By the use of iron vessels, however, the loss of ammonia may be avoided; the copper can be recovered as oxide by distilling off the ammonia, which can thus be recovered." The experiments made in Germany were on natural oxides and roasted ore, Mr. Benedict being the first to apply the method to the treatment of native copper.

In carrying out the process at the Calumet & Hecla, sixteen 1000-ton vats, 54 feet in diameter and 12 feet deep, will be employed in a 91 to 96-hour cycle for the treatment of the ore. In treating a sand containing 12 to 13 pounds of copper per ton, 5½ to 6 pounds will be recovered by the regrinding and table treatment, and 4½ to 5 pounds will be recovered by leaching. It is estimated that the cost of the leaching will not exceed 35 cents per ton, and the recovery will exceed 70 per cent.

The contract for the construction of the plant has been let to the Riter Conley Manufacturing Company, and one-half of the 4000-ton plant was in process of erection till recently stopped. Its success depends upon whether the recovery of the ammonia, which has a strong vapor pressure at ordinary temperatures and consequently constantly tends to escape into the surrounding atmosphere and be lost, will be as complete in the full-sized plant as was indicated by the laboratory experiments. In the use of this reaction for the absorption of oxygen, the working solution is made by mixing equal volumes of NH_4OH, 0.93 specific gravity, and a saturated solution of commercial $(NH_4)_2CO_3$. Doubtless the solution used in this case will be more dilute. At a later date we hope to be able to present a detailed account of the process by Mr. Benedict himself, to whom the greatest credit for skillful metallurgical work is due. If the process proves successful on native copper, it may prove feasible to apply it to roasted ores.

As It Looks in London*

By T. A. RICKARD

Your Sherman said that "war is hell." Another has said that "the essence of war is violence and moderation in war is imbecility." This appears to have been learned by our Admiralty and War Office, for they are going ahead at full steam and with intense vigor. The Government is accepting the offers of troops from the overseas Dominions; even if these arrive late and are used for defence only, their coming will be a fact of unexampled eloquence.

The lowering of the Bank rate to 5% within six days of the sudden rise to 10% is a symptom of sound financial conditions. The closing of our Stock Exchange was due entirely to the use made of it as a dump for all the panic-stricken sellings from the Continent. The city is quiet. People go about their business without hysterics. We don't use motor-cars and we restrict ourselves to one course at luncheon. We smoke pipes instead of cigars. We are prepared to go on rations. The suffragettes have ceased to be a worry and the name of Ulster suggests an island in the South seas. We are one. When the Prime Minister asked for $500,000,000, he got it in five minutes; and when the Earl Kitchener of Khartoum (K. K., as he is known, for short) asked for a half million more soldiers, he was promised them forthwith. The first issue (to speak in terms of a prospectus) of 100,000 has been over-subscribed.

As you know, I have no experience in military affairs, but as a detached onlooker (which is the true pose of a journalist), I venture to predict that this war will establish one supremely important fact, namely, an enormous enhancement of the power of the defence. In the wars of other days it was possible to capture defended positions by a rush of men and a hand-to-hand fight on a breach or in the trenches. Effective shooting began at a hundred yards, so that the enemy were near before they could be stopped. Now, with modern arms of precision, the enemy are under rifle-fire at half a mile, not to mention the correspondingly longer and more accurate range of artillery. Whereas a defensive position could be attacked in the ratio of 2 to 1, it will be necessary nowadays to increase the ratio to 10 to 1. The story of Liége is an illustration. That, of course, is the outstanding episode of the first week of this Armageddon. Some people talk of the Belgians as a non-military people. As a matter of fact their Ecole Militaire is one of the best soldier-schools in Europe and Liége itself is considered by experts as one of the strongest of the ring-fortresses within the area of conflict. You will remember that it is the seat of an important zinc-smelting industry, and it is also the place where an Englishman, John Cockerill, founded a steel industry of international fame. The closing of the Belgian smelters has already affected some of the Broken Hill mines, which have been sending their zinc concentrate to Antwerp for treatment near Liége by the Vieille Montagne company. In the same way, the lead concentrate that went from Broken Hill to Rhenish Prussia is now without a market. The closing of these smelters, as well as those at Essen and Hamburg, will be felt in localities far from Europe and may have the effect of shifting smelting industries permanently. However, these and other far-reaching changes inevitably imminent, must depend upon the outcome of the struggle.

August 9.

The South African mining companies are postponing the distribution of their half-yearly dividends. As these in the aggregate amount to $20,000,000, this is an important matter. It looked at first like 'hoarding' of the most objectionable character, for the companies don't need the money, they have the whole of the July gold output already as a reserve at Johannesburg, and gold bullion in times like these is the most liquid of all assets. The ostensible reason given for withholding the dividends is that the war renders it impracticable to send the money to shareholders on the Continent. I enquired this morning, and find that the Postoffice will take mail for France and Russia; indeed, everywhere except to Germany and Austria. On further investigation, the true reason for not distributing the dividends was made clear. The money, of course, does not lie idle at the banks, it is lent at interest subject to recall, which, however, is not now possible owing to the moratorium. A moratorium, in simple terms, is a suspension of the payment of debts.

Systematic efforts are being made to assist Americans stranded in London. Some of your friends and mine have organized a committee of American residents for the relief of those in trouble. H. C. Hoover is chairman, and has worked like a Trojan. On the committee are Edgar Rickard, J. P. Hutchins, Jack Hoffmann, H. A. Titcomb, A. F. Kuehn, and A. C. Beatty. Mrs. Hoover is at the head of the ladies committee, which includes Mrs. R. Gilman Brown (Brown himself just now is at Tanalyk, in Western Siberia), Mrs. Edgar Rickard, Mrs. Charles Janin, Mrs. Hutchins (only recently known as Miss Bessie McNear), and Miss Daisy Polk—the last the sister of your well-known architect. Edgar was telling me this morning that one of the lady refugees, expelled suddenly out of a German hospital after a capital operation and subsequently exposed to severe hardship, has committed suicide. Half-a-dozen German residents from your side that had only declared their intention of becoming Americans asked for help. This makes serious legal difficulties.

August 11.

*In this series of war letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies, but he will endeavor to be as impartial as he may.

The Labor Crisis in Chile*

By BANCROFT GORE

The digging of the Panama canal has had the effect of arousing in this country a widespread interest in conditions along the west coast of South America. As three out of five of the republics that are soon to be brought into direct communication with us are essentially mineral producing, it is not surprising that we, as mining engineers, should be most interested in the developments in our line of work that are taking place in these countries. A discussion of conditions in Colombia and Ecuador does not fall within the scope of this paper, but the labor situation may be summarized by remarking that although they are undoubtedly rich in placer and dredging ground, these attractive deposits are generally in places where the white man cannot live and the black man or Indian will not work.

In Peru, mining operations are not under such a handicap, but the mines are unfortunately at extreme altitudes, where the efficiency of the miner is low; moreover he is small in stature, slow in action, and not over muscular; furthermore, he will only work in the mine or smelter during such seasons as he is not busy on his own little farm, distant many hundreds of miles.

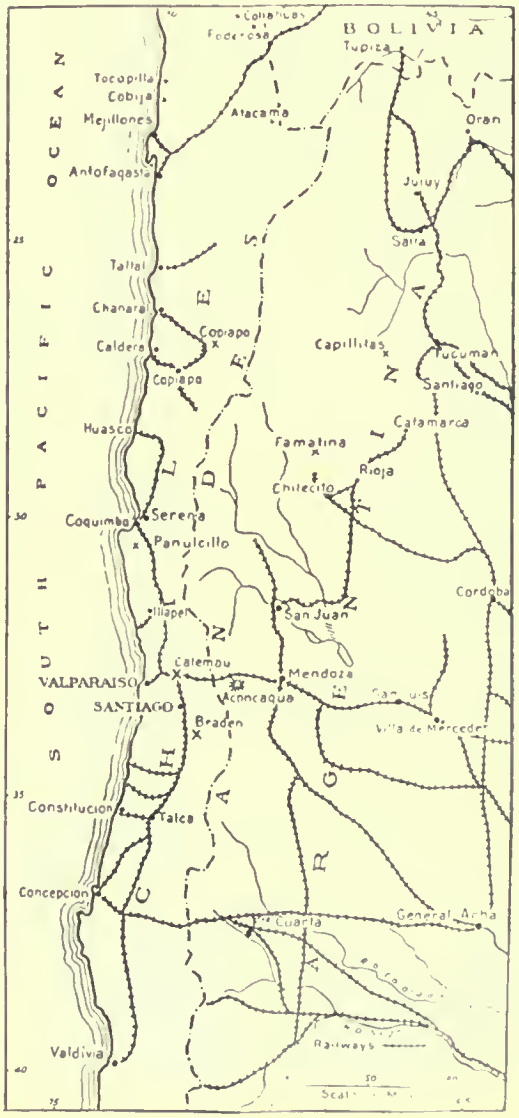
Passing southward one leaves the enervating tropics and reaches a country far more favorable for mining operations. One then passes along that thin slice of seacoast known as Chile, which if placed across the United States would reach from New York to San Francisco, but with an average width corresponding to the distance between Chicago and Milwaukee, just 87 miles. Here is a great mineral country, favored by a healthful, temperate climate, where work, especially in the northern provinces can go on every day, peopled by a vigorous active race, under a strong centralized government, offering every protection and encouragement to foreign capital, especially freedom from the endless varieties of taxation found in other Latin-American countries. Nowhere is it very distant from tidewater, where competing steamship lines afford direct communication with Europe.

First in order of importance are the only commercial deposits of nitrate of soda in the world. Scientists have sounded many cries of alarm in the past showing the calamities that would arise from the depletion of these Chilean saltpeter beds, little knowing of their extent and depth. European countries, and especially Germany, would suffer an agricultural crisis were the supply of this plant-stimulating salt cut off. Consequently in Europe there is most active research for fixation of nitrogen from the atmosphere and by synthetic methods.

What has happened in Chile has not been any appreciable exhaustion of the nitrate resources of the country, although the shipments between the years 1878 and 1907 exceeded 29,000,000 metric tons, valued at nearly a thousand million dollars. These figures are official returns from the Estadistica Minera de Chile for the year 1909. It is true that the richest spots have been worked up by those who had first selection of the ground, but recent government investigation of the nitrate zone indicates an available tonnage adequate to supply the world for another century without making allowance for the use of artificial products.

What is found instead is a critical situation in regard to labor conditions that has increased the difficulties and incidentally the cost of digging the crude salt, refining it near by, transporting it to the coast, and getting it on board for export, thereby giving the artificial nitrate a firm foothold in the markets of the world.

Last year a tramp steamer from Europe dropped anchor in Iquique harbor, the leading nitrate port of the



*The title of this paper, which was read at Butte before the Montana section of the Amer. Inst. Min. Engineers, was suggested by a pamphlet issued from the Chilean Bureau of Statistics, written by its director, Francisco de Béze, entitled 'La Población de Chile,' Santiago, Chile, 1911. It is a brief but fearless criticism of the economic conditions of the country, especially the neglect by the governing classes of the workman and his family. It had been popularly supposed, previous to the taking of the last official census of 1907, that the total population was between five and six millions, but the final count gave 3,249,279, an increase of only 1.52% per annum since the census of 1895.

country, en route to the Hawaiian islands with a cargo of artificial nitrate, showing how this product, made almost without muscular effort, had won out in competition with the natural salt depending for its production and refining upon arduous labor operations in a desert country where labor is scarce and difficult to manage.

Read what the director of the Chilean bureau of statisties, Francisco de Béze, reviewing the last census taken in 1907, says: "As regards the increase in population (and it has about doubled in the past 50 years), it does not take much philosophy to prove clearly that our nation moves ahead at the speed of a tortoise."[2]

This in a country where American enterprise in the short interval of two years has proved the largest of all known copper deposits and one of the richest mines of bessemer iron.

The Labor Shortage

But the nitrate business, although the most important, is not the only one to feel the effects of the critical shortage of labor. The borax industry, developed to a point where Chile is now the second producer in the world, is having troubles also. Then there is the copper business. Many can remember when copper was synonymous with the name Chile, which, up to the opening of the Anaconda mine, produced more copper than all of North America. This copper, mainly exported in the form of so-called Chile bars, was the product of scores of small establishments, situated generally at favorable harbors along 1500 miles of seacoast and drawing their ore supply from thousands of copper mines, many of them mere gopher holes, yielding, with careful and laborious sorting, a few sacks daily of high-grade ore, which found its way on mule-back to the coast, where there was either a smelter or a receiving station, where ores accumulated until a cargo was on hand for shipment to some reduction works, generally of the reverberatory type, along the coast.

The force employed at mine and smelter was large in comparison to output, but wages were low in those days, and the necessities of the workman limited, compared to what he now thinks he needs. Furthermore, families were large and everyone worked, including father. The domestic bill of fare was a frugal one and meat a luxury. Flour sacks were made into articles of clothing entirely adequate for the mild climate. For shoes each was satisfied with canvas sandals with braided hemp soles. They lasted a month or two and cost little for renewal.

Then came a world-wide demand for the products of advanced civilization. It spread to Chile as elsewhere. Factories for the manufacture of shoes patterned after the latest models from the United States did a flourishing business. Ready made clothing became popular. Reed hats gave way to imported felts, the starched linen collar and the bright satin four-in-hand were omnipresent.

All these cost money, but the laborer soon found out that he could obtain higher wages by demanding them. His employer had no one to take his place and there was work everywhere, and for reasons shown a little later on, there was no immigration into the country; in fact there never had been any. Valparaiso and a part of Santiago de Chile had to be rebuilt after the earthquake, long lines of government railroads were to be constructed, extensive harbor improvements were authorized, a new porphyry copper mine was added to the list of producing properties after an expenditure of more than $15,000,000. These are some of the undertakings that called for labor. Heretofore the nitrate works and copper mines in the northern provinces had been the only big employers. Their agents canvassed incessantly the southern agricultural districts where employment on the large estates was intermittent and at low wages. The inducements offered were steady employment at more than double the wages, with free transportation by rail and steamer to the north, free living quarters, and medical attendance.

There came a time when these agents could find no more recruits, and somebody thought of Argentina as a possible field for obtaining laborers. What was their astonishment to find that Argentina, in spite of the steady influx of immigrants from Europe, was short of harvest hands, and none could be persuaded to cross the Andes and work on the Atacama and Tarapaca deserts of Northern Chile while there was plenty of work at good wages close at hand, with opportunities for the foreigner to become a small land owner, which was virtually impossible in Chile. Moreover, many of the laborers in Argentina held tickets back to Italy and Portugal, having come over between the planting and harvesting of their own crops to save a little capital for improvements later on at home. Chile had no charms for them.

Reference to the nitrate exports for the past three years shows practically no increase.[3] This was foreseen by government officials as far back as 1902, and commissions were appointed to study the situation from every point of view and report on possible remedies.

Governmental Studies of Labor

Now if there is any government in the world that can place an exact valuation on the man with the shovel it is Chile. In 1910 there was collected at various nitrate ports and turned into the treasury the sum of $28,679,550 from the export tax on nitrate. Engaged in the mining, refining, transportation, shipping, and industries sustained directly by the nitrate industries, such as powder works and sulphur mines, was a force of some 70,000 men and boys, each of whom contributed directly to the government expenses the sum of $410, being the export tax on nitrate produced by his labor. As it has been found impossible to substitute European or Asiatic labor for this nitrate work, and there was no longer any hope of increasing this force by recruits from the south, it is not difficult to calculate the value to the Government of these workmen in dollars and cents. The loss of

[2]'La Población de Chile,' page 50; Francisco de Béze, Santiago, Chile, 1911.

[3]See 'Mineral Industry,' Vol. XXI, page 776.

any one of them meant a loss in income of $410, which is the interest at 4% on about $10,000. When one died it was like the loss to the Government of a $10,000 4% bond. Or, putting it the other way round, an increase of population that would make available for work in the nitrate zone 100 able bodied men was like dropping a million-dollar bond into the laps of those few hundred aristocratic families who own and hold the best agricultural land, two thirds of all the city property, and who are the Government. Yet this same Government, just two years ago, debated for a whole week as to whether an appropriation of $40,000 to stamp out yellow fever in the panic-stricken nitrate port of Tocopilla, where local authorities were helpless and a dozen unfortunates were dying every day, should not be cut down to $20,000.

From what has been said thus far it can readily be imagined that there are no men outside of any big establishment in Chile, be it nitrate, borax, copper or iron, wanting for the opportunity to be given employment or the chance to fill a possible vacancy; no long line of applicants, such as was shown recently by one of our local papers, waiting in hopes of employment underground. And it is this very situation that makes the handling of the Chilean workman a very delicate undertaking, and the character of his work very unsatisfactory, because he knows there is no one to take his place and that his employer will stand all manner of nonsense rather than reduce production by discharging him. He comes to work when he pleases, is arrogant, insolent, and full of complaints for more wages and lower prices at the company store. He has five meals a day, three of which include beefsteak, and he little knows the effort and expense to which each company goes in order that the supply of steaks does not run short. Competition for labor among the big companies has brought the price of this meat to the working man far below its actual cost at the nitrate works.

He has no rental, as he lives on company property; no doctors' bills and small fuel expense, as the climate is such that no heating stoves are needed. Most of his supplies are sold to him at their wholesale cost to the company. This was not the case ten years ago, when one of these stores was a veritable gold mine to those in charge. He takes frequent lay-offs, always without notice, and if offended at his reception on returning to work, will disappear in the night and be welcomed personally like a prodigal son by the manager of some adjoining property.

Increasing the wages only results in the man working fewer days each month. He is paid every day in the hope that his cash capital may never reach the value of

A FOOT-BALL TEAM, SHOVEL GANG, AND BAND MADE UP OF CHILEAN LABORERS.

a case of beer or demijohn of artificial wine, but he gets them in spite of this. He is offered a bonus as high as 20% of his wages if he has worked every day in the month, but without arousing his ambition.

Wherever possible, payments are made on a piece-work basis, generally per ton of material handled. Under these conditions he is a fast worker. Where cargoes have to be loaded or discharged within time limits, he knows only too well that time is money, and holds up his employer for all the tariff will bear. From $2 to $3 United States currency is what these men can earn in eight hours, but it is the very hardest kind of labor.

In our own country 30 years ago there was almost the same situation in the unloading of iron-ore boats on the Great Lakes. The hand shoveling of this ore into tubs and afterward wheeling it up by hand to the stock piles required a class of labor that could stand up under extreme physical exertion. There was always a shortage of men, and those who came to work were unreasonable, strikes were common, and high wages prevailed until mechanical engineers eliminated this heavy labor, with the result that today 13,000 tons can be unloaded from one vessel in 3 hours and 20 minutes by 25 men.[4]

Herein lies the remedy for the labor conditions in Chile. Labor-saving machinery alone can save the situation. It is true much of it must be of special design, particularly for the digging and sorting of the nitrate. In the mines the very latest mechanical appliances are needed.

One step in this direction has already been made by substituting fuel oil for coal at many of the nitrate works. The cost per million British thermal units of each fuel is more or less the same, but a 6000-ton oil steamer can pump its cargo ashore in 48 hours, while to discharge the equivalent fuel in the form of coal would require unloading three sailing vessels of 3000 tons each, and keep a crew of 20 men, six barges, two donkey engines, and a locomotive busy for six weeks.

With reference to the refining of the crude nitrate, it is significant that a banking house heavily interested in nitrate works has recently consulted with well known metallurgists in this country, experienced in the design of successful cyaniding equipment, with the idea of overcoming the wasteful and laborious methods now in use, for here indeed is a hydrometallurgical problem that has never been thoroughly worked out, and one in which the chemist and mechanical engineer have a most excellent field for endeavor, the former to improve without excessive cost a recovery of nitrate that seldom exceeds 75%, and the latter to eliminate labor at every possible point.[5]

[4]'Handling the Raw Materials at the Iron Blast-furnace,' J. E. Johnson, Jr., *Met. and Chem. Eng.*, Jan. 1914.

[5]Large investments have been made from time to time in new processes claiming to be improvements over established methods for the recovery of sodium nitrate from the crude *caliche*. These plants have all been abandoned owing to difficulties not foreseen by the inventors. A new 'ammonia process' is under investigation. The field for improvement still remains, however.

There are two more suggestions which if put in practice by the large operating companies would tend to relieve somewhat the present crisis. Keep down the death rate of your force. Don't appeal to the local authorities, invariably without funds, or the chamber of deputies, 1000 miles away, if typhoid, smallpox, or yellow fever is raging in your midst. At least one-third of all deaths in Chile are preventable, and if it were not for one of the largest birth rates in the world the country would have been depopulated long ago. They die of consumption under the same climatic conditions that are utilized in the United States to cure this disease. Their houses need ventilation, more rooms for the large families, board floors, pure water supply, and rigid sanitary inspection. Doctors are scarce, in spite of the great need for them. One doctor to 3000 workmen is the rule in the nitrate zone. Accidents alone keep him busy, and there is no time for preventive measures, so the death rate remains high.

The workman and his family have been sadly neglected by an opulent government. In no other way can the inertia on its part be explained when it comes to meeting these problems face to face and doing something to keep down the high death rate, especially among the children: of improving the sanitary condition of streets and dwellings of the lower class; of purifying the contaminated water supply of most of its centres of population, and restricting the use of alcohol.

Finally, it was noticeable that the few large operating companies, both in nitrate and copper, that had the least difficulties in keeping up production or new construction work were those that had undertaken in a systematic way to look after the welfare of their employees and families, by building hygienic houses instead of disease-breeding shacks, enforcing sanitary precautions, providing adequate medical attendance, patronizing liberally local athletic organizations, and encouraging every form of innocent entertainment for the diversion and improvement of their force.

Iron ore mined in 28 states of the Union in 1913 amounted to 61,980,437 long tons, compared with 55,150,147 tons in 1912, according to the U. S. Geological Survey. Ore shipped from the mines totaled 59,643,098 tons, valued at $130,905,558. The totals in 1912 were 57,017,614 tons and $107,050,153, respectively. The average price for the whole country was $2.19 per ton, against $1.88 in 1912. Some of the states produced ore only for fluxing purposes. The principal states were Minnesota, Michigan, Alabama, New York, and Wisconsin, in the order given. The Mesabi range produced 69.46% of the total.

Bullion returns for July from two of the principal mines of New Zealand were as follows: Waihi, 15,057 tons of ore for £25,889; and Waihi Grand Junction, 9320 tons for £19,072. The respective totals to date are £10,608,786 and £4,631,797 in dividends; and £916,767 and £80,000 in dividends.

Ventilation in the Iron Mines of the Lake Superior District

By EDWIN HIGGINS

Introduction

*I am at present engaged in collaboration with associated mining engineers and chemists, in the investigation of ventilation in the metal mines of the United States for the Bureau of Mines. In the course of the field work visits were made to nearly all the mines in Michigan and Wisconsin, and some of those on the Mesabi and Vermillion ranges in Minnesota. Although many air samples were taken, their analyses will be made use of only in pointing out general conditions.

All the mines visited, with the exception of two, depended on natural ventilation for the supply of air to the working places. Of the two exceptions, one mine had a blower fan installed underground, and in the other the air was kept in motion by means of compressed air jets. In a few cases booster fans were found in use in dead ends, especially in those immediately under the timber mat. The amount of air entering the mines per man employed underground varied greatly, but in the majority of cases was between 50 to 100 cu. ft. per man per minute. The analyses of many air samples showed that seldom in the main airways did the air contain any appreciable amount of noxious gases. Invariably the heavily timbered mines showed a higher percentage of carbon dioxide in the return air than did those mines in which little timber is used.

The temperature of the fresh down-cast air varied according to the season of the year. Summer temperatures may be said to range from 50° (nights) to a maximum of 100°F. (days) in the shade; in the winter temperatures range from about zero to a maximum of 30 to 40°F. below. At all times the humidity is comparatively low. In the deeper mines (1000 ft. or more) the temperature underground showed little variation, no matter what the temperature on the surface. In the shallower mines, however, it is common in winter to see huge icicles, in some cases as deep as 300 ft. from the collar of the down-cast shaft. In the heavily timbered mines, the return air ranged in temperature from 75 to 90°, and humidity usually from 95 to 100%. In mines where little timber is used the return air is from 10 to 15° cooler.

Gases in the Mines and Their Effects

With the exception of the combustible hydro-carbon gases reported from time to time from some of the mines situated in the carbonaceous black slate area of the Menominee range, the only noxious gas that is encountered under ordinary operating conditions is carbon dioxide. No explosive gases occur.

In mines, carbon dioxide (CO_2) is produced by the breathing of men or animals, the combustion of timber and explosives, the burning of lamps, and the decay of timber or other vegetable matter. When the human being breathes air containing about 10% of carbon dioxide life becomes imperiled. Candles in air are usually extinguished when the oxygen content decreases to 16 or 17%. Carbon dioxide that may be present has but slight effect upon the extinguishment. Carbide lamps become extinguished when the oxygen decreases to about 12%. There are produced by the combustion of explosives varying percentages of hydrogen, methane, oxides of nitrogen, carbon monoxide, water vapor, and hydrogen sulphide. Very small percentages of either carbon monoxide, oxides of nitrogen, or hydrogen sulphide have marked effects upon the human system. One-tenth of one per cent of any of these gases have a serious effect upon the miner.

Carbon monoxide (CO) is far more deadly than carbon dioxide in its poisonous effect on the system. It is a product of incomplete combustion of wood or other combustible matter, also of the explosion of various types of blasting powder or dynamite. The amount produced is enormously increased when the explosive burns instead of detonating. Carbon monoxide is more than likely to be encountered during a smouldering fire, such as would result in a damp or wet mine. As little as 0.2% of this gas will cause death if breathed for a sufficient length of time. It acts as a cumulative poison to the human system by combining with the haemoglobin of the blood, thus preventing that agent from combining with sufficient oxygen to support life. It gives little or no warning of its effect on the system. The person breathing it usually becomes suddenly weak in the knees and lapses into unconsciousness. Carbon monoxide may occur in quantities sufficient to cause sudden death, and still its presence will not be indicated by the dimming of the candle flame. Thus it may be seen that the belief of many miners that they can live wherever a candle will burn, is erroneous.

Effect of High Temperatures and Humidity

That high temperatures and extreme humidity have a marked effect in lessening the efficiency of the miner, there can be no doubt. In this connection Haldane[1] says: "The normal body temperature of a man is from 98 to 101°F., and in order to obtain efficiency in work, his temperature should not exceed this upper limit. The body may be cooled by radiation, conduction, and evaporation (sweating). Cooling by evaporation is the most important in deep mine ventilation. Evaporation from

*Condensed from a paper prepared for Marquette Range meeting of the Lake Superior Mining Institute, August 31, September 1, 2, and 3, 1914.

[1] J.S. Haldane, *Jour.* Chem. Met. & Min. Soc. South Africa, Vol. 11, 1910, page 227.

the body can only occur when the dew point of the surrounding air is below body temperature, 98°F. * * * In order to maintain the body temperature in hot mines, where one is working, it is necessary to keep the skin at a lower temperature than the interior of the body. The body temperature may be maintained when 78°F. wet bulb in still air, and 88°F. wet bulb in good moving air, is shown. * * *''

According to G. J. Young:[2] "With a temperature from 95 to 105°F., and relative humidity 50 to 70% in still air, miners can do efficient work. From 110 to 115° F., and with other conditions the same as above, efficient work cannot be done. Increasing the velocity of the air, with other conditions the same as above, makes work more bearable, but miners cannot work very long at a time under such conditions. Saturated air at 95 to 105°F., and velocity, is dangerous; 90 to 98°F., saturated velocity of air current 400 to 500 ft. per minute, and slightly vitiated, will prevent efficient labor. Impurities in the mine air seem to hinder labor efficiency more than high temperatures do. The humidity of the air depends upon the amount of water in the mine and the dryness of the down-cast air."

High temperatures in a comparatively dry air do not have so great an effect on the miner. This fact was forcefully illustrated to me on a recent trip through the Comstock mines in Nevada. In one place the dry bulb thermometer read 110°F., and the wet bulb 100°. This represents a humidity of 70%. While performing no work the place was not unbearably hot. Nearby, where the return air current was encountered, the wet and dry bulbs both read 110° (representing a humidity of 100%) and the effect was distressing.

High Temperature and Efficiency

By frequent observations in many of the Lake Superior iron mines, I have noted repeatedly that miners working in temperatures above 75° wet bulb (relative humidity 100%) showed a marked falling off in energy. At wet bulb temperature of from 80 to 90° (relative humidity 90 to 100%) the average miner works only from one-half to one-third of his time; when he is at work under these conditions his efficiency is not normal, and when he is resting, of course, his time is entirely lost. In one mine four miners produced the same tonnage of ore as was produced by nine miners in a similar place in the same mine where the temperature was 10° warmer. Many cases of this kind could be cited.

Without going into a detailed discussion, it may be stated that in heavily timbered mines (especially where the mine is wet or damp) the timbers consume from three to four times as much oxygen as do all the other factors combined. Recognizing the importance of this phase of the problem, an investigation was instituted at the Pittsburgh laboratories of the Bureau of Mines. While the work done to date has been only preliminary, some interesting facts have been brought out. The investigation is being carried on by G. A. Burrell, chemist of the Bureau, whose results show that timber in metal mines (where large quantities of it are used) may be responsible for part of the vitiation of the air therein, especially in dead ends where the air is stagnant, the wood moist, and much timber is present. The state of division of the wood is undoubtedly very important. Further experimenting is required to determine the action between air and timbers. The rock in some metal mines, especially if iron pyrite is present, is probably responsible for some of the oxygen disappearance. Many of the samples of mine air collected by the Bureau, however, have shown a quantity of carbon dioxide almost proportional to the oxygen disappearance, suggesting that the timber or some reaction that is analogous to that taking place between air and wood is responsible for the vitiation of the air.

[2] *Jour.* Chem. & Min. Soc. South Africa, Vol. 11, 1910, page 411.

Heat and Humidity in the Mines

In general, it may be said that heat is developed in mines through the following agencies: rock temperatures; presence of men and lights; crushing and working of rock and timbers, and possibly the oxidation of timbers; operation of machinery and presence of steam lines connected thereto.

The cause of humidity, of course, is the absorption of moisture in the mine by the comparatively dry air admitted from outside. In practically every case in the Lake Superior district the air issuing from mines was found to range between 95 and 100% in humidity.

It was found that rock temperatures had practically no bearing on the great heat encountered in the sub-levels, especially those levels directly under the timber mat. In several cases rock temperatures, at depths of 1500 to 2000 ft., were as much as 10° lower than air temperatures from 500 to 1000 ft. nearer the surface (under the timber mat). Air currents passing through timbered workings where no men were employed were tested at various intervals, and the temperatures were found to increase gradually, regardless of whether the course of the air was downward or upward. With respect to working places, then, the other causes mentioned may be disposed of as of small importance in causing a rise in temperature, with the exception of the crushing and working of the rock and timbers, and the oxidation of the latter. While the laboratory investigations have not progressed far enough as yet to make a positive statement in this connection, it is my opinion, from observations made in the field, that in these mines the oxidation of the timber is the chief cause of the production of heat. In one mine a new sub-level was opened under the sub directly beneath the timber mat. Before the introduction of timber in this new sub the temperature averaged 75°; when drift sets had been put in the average temperature of the level was 80 degrees.

The Problem

There are two problems presented in the proper ventilation of Lake Superior iron mines.

1. The supply of a sufficient quantity of air, and its proper distribution, so that it will carry off the noxious gases produced; and have the effect of lowering the temperature and humidity existing in working places.

2. The production of less quantities of noxious gases.

It is difficult to state just how much air should be supplied in the heavily timbered mines, for the reason that there is no accurate method of calculating how much oxygen the timbers will consume. The factors affecting this are extremely variable. Damp timbers are much more active in oxygen consumption than are dry timbers. Again, due to the methods of mining, it is impossible to figure with any degree of accuracy the amount of timber in a mine. However, a study of actual conditions leads me to the belief that, in untimbered mines, where no animals are used, 50 cu. ft. per minute per man employed underground, is sufficient air. In mines where a moderate amount of timber is used there should be 100 cu. ft. per minute per man employed underground. In the heavily timbered mines, it may be necessary to increase the amount to 150 or even 200 ft. per minute.

There are several guides in determining whether or not there is a sufficient amount of air entering the mine. In the first place there should be sufficient air to prevent the humidity in working places from rising higher than 90%. With 90% humidity the wet bulb thermometer should not read more than 80° in still air, and 85° in a current of 400 to 500 ft. per minute; with 100% humidity these figures may be set at 75 to 80 per cent.

Amount of Oxygen Necessary

The second consideration is the diminution of the amount of oxygen in the air. As pointed out, this is closely related, in the Lake Superior iron mines, to the amount of carbon dioxide in the air. In England, ventilation requirements deal with the oxygen and the amount of carbon dioxide in the air. The requirements (not less than 19% oxygen, or more than 1.25% carbon dioxide), refer to coal mining, in which the ratio between the oxygen and carbon dioxide contained in the air is not as constant as it is in metal mines.

While a miner may feel no discomfort while not exerting himself, in an atmosphere in which a candle will become extinguished (from 16 to 17% oxygen), the effect may be very different when carbon dioxide is present and he is working hard. Another factor to be considered is the heat usually encountered in places containing vitiated air. I have noted miners, when working, showing ill effects in an atmosphere containing 1% carbon dioxide and 19.7% oxygen, the temperature being 75° and the relative humidity 95%. It is my belief that miners will begin to lose efficiency in air containing more than 1.25% carbon dioxide and less than 19% oxygen, in ordinarily cool temperatures; when the working place is hot the effect is correspondingly worse. Recommendations for the Rand mines by S. Perlerich[3] are: That sufficient air shall be provided so that in one hour after a shot is fired, a sample taken anywhere in the mine will not contain more than 0.2% carbon dioxide, and 0.01% carbon monoxide, and only traces of the oxides of nitrogen.

[3] *Jour.* Chem. Met. & Min. Soc. of South Africa, Vol. 11, 1910, page 59.

Remedial Measures

The principal remedy for the conditions referred to is a sufficient air supply, and its proper distribution throughout the mine. Increased air supply may be effected: (a) by providing a greater number of openings to the mine; (b) providing for down-cast and up-cast openings, with due regard to the elevation of the shaft collars, and the presence or absence of steam pipes in the shaft; (c) by the use of fans either at the shaft collar or within the mine. A blower fan at the collar of the down-cast shaft is preferable. If an air shaft is not available, that is, one that is not used for hoisting, it may be possible to use the manway in an operating shaft as an airway, but in this case the partition between the manway and the hoisting compartments must be absolutely tight. If it is not practicable to place the fan at the shaft collar, it must then be placed within the mine workings, preferably a blower fan somewhere near the down-cast shaft.

Many of the mines have a sufficient amount of air passing into them, but, owing to insufficient airways, most of the air escapes from the mine without reaching the working places. Such conditions can be remedied by the running of additional cross-cuts, drifts, and raises for carrying the air, and by the installation, at proper places, of doors and brattices. An important aid in ventilating dead ends may be found in the intelligent use of electrically operated booster fans.

With regard to measures looking to a reduction in the noxious gas produced in the mine, those worthy of consideration are: (a) The treatment of timber with such preservatives as will prevent or retard oxidation or rotting, and (b) the use of explosives that produce a minimum amount of noxious gases. The treatment of timber has been discussed in various papers and publications, and it is probable that the use of some preservative that will act as a sterilizing agent will be effective in the Lake Superior mines. Probably the preservative most used at this time is creosote. However, this is a subject that requires further investigation before definite recommendations can be made. The cost of treatment is an important factor. It might be added that stripping the bark from timber retards, to some extent, its liability to oxidation.

The antimony supply is cut off on account of the war. In the United States, deposits of stibnite (antimony sulphide) near Gilham, Arkansas; Battle Mountain, Lovelocks, and Austin, Nevada; Burke and Kingston, Idaho; Tonasket, Okanogan county, Washington; Graniteville and San Emigdio cañon, California; Antimony, Utah; Red Bridge, Oregon; and other places, are potentially productive in times of prices as high as those now prevailing, over 20c. per pound.

The Daly West New Mill

Near the end of 1913 the mill on this property was destroyed by fire. Since then the flow-sheet of a mill to make a high recovery of zinc and other metals from the ore was devised, and a new mill is now being erected in charge of F. W. Sherman, who gave the following description to the *Park City Record*. John C. Thompson is in charge of grading, and construction is under John Steffers.

The Flow-Sheet

Ore from the mine will be received at the mill in two ore-bins, 12 by 12 ft. square and 35 ft. deep, and fed to Stevens-Adamson pan feeders and delivered to grizzlies. The undersize passes direct to a trommel screen, the oversize going by gravity to a 10 by 12-in. Blake crusher, which crushes to two inches, and this product passes to a trommel screen. The undersize of the trommel goes by gravity to a conveyor belt and thence to an ore-bin in mill proper, and the oversize is delivered to a 10-ft. long conveyor belt, that in turn delivers it to a 48-in. Symons fine disc crusher, weighing 20 tons. The head pulley of the small conveyor is magnetic and picks out any iron or steel before delivering to the crusher. Feed from the crusher goes to a conveyor belt delivering to mill ore-bin. Near the head of conveyor belt is a set of Blake-Dennison scales which weighs and registers weights of ores while in transit on the belt. This conveyor belt is 175 ft. centres. One man will operate the crushing department.

The bins at the top of the mill will be each 100-ton capacity. The conveyor will deliver ore to the above bins through a trommel screen, where two sizes are made, the undersize of 6 mesh and the oversize of 6 mesh. The oversize is delivered by a plunger feeder to a Franz jig. This jig makes a lead concentrate and a middling. The middling is delivered automatically by a drag conveyor to an ore-bin where a plunger feeder delivers it to rolls for re-crushing. The undersize product of trommel screen at head of mill is delivered by a plunger feeder to an Akins de-slimer where the slime is taken out. This is an entirely new feature in milling. The de-slimed product is delivered automatically to a second Franz jig that makes a lead concentrate, a lead-zinc middling, and a tailing which is in turn delivered to the sizing and classifying system, which consists of a series of three Akins impact screens, three screens in each series, and also a five-spigot Richards-Janey classifier. The impact screen and classifier make eight different classes of material. The first three classes are treated each over two three-compartment Harz jigs. The other five classes are first treated each over two Wilfley tables. On the jigs is made a lead concentrate, a lead-zinc middling, a zinc concentrate, and a tailing rejection. The middling from each jig is treated on an Overstrom table, which in turn makes a lead concentrate, an iron-zinc middling, a zinc concentrating rejection. Each series of the Wilfley tables makes a lead concentrate, an iron-zinc middling, a zinc concentrate, a zinc-silica middling, and a tailing rejection. The middling from each series of two tables goes by gravity to the floor below to a third Wilfley table where the same number of products are made as on the tables on the floor above. The middling from the lower series of tables is returned by a cup elevator to the sizing and classifying system. The lead and zinc concentrates from all the tables and jigs go to separate shaking launders that in turn deliver them to separate cup elevators that deliver each class of concentrates to Akins de-waterers. The de-watered concentrates drop into bins from which they will be loaded into cars for delivery to railroad.

The overflow from the Richards-Janey classifier, which contains all the original slime in the ore, is delivered by gravity to a Sherman classifying tank, 14 ft. diameter and 12 ft. deep, from which the coarser slime is drawn on a series of two slime tables for treatment. The middling from these tables is treated over a third slimer on the floor below. The overflow from the tank is delivered and equally distributed to 32 settling tanks, where the slime is thoroughly settled and thickened, and then delivered by gravity to a flotation machine. This machine gives a thickened slime product 14 separate treatments: from each treatment a froth concentrate is made. The overflow water from the tanks will be so clarified that it will again be used in the mill in place of fresh water.

All tailing rejections from jigs and tables pass over a Harz jig as a last treatment before being finally rejected. On this jig is made a middling and a tailing rejection. The middling is returned to the sizing and classifying system and thence to jigs and tables for re-treatment.

Automatic Handling and Labor Costs

When completed there is no doubt the Daly West will be one of the best mills in the district. The latest milling machinery will be in use, and modern methods adopted in every detail of operation. In the mill proper there will not be a car track, not a shovel used, or a tank of any description. All products will drop direct from machines to shaking launders into tunnels beneath the floor and automatically carried to their respective destinations. This will enable the mill to be kept clean and neat. A 150-ft. tunnel runs from the end of the mill underneath ore-bins to the mine, and all transportation will be done electrically. Below the mill will be a heating plant for both mine and mill. The difference in cost of operation under the new system will be an item of considerable importance. Records show that the last year in the old mill the cost for labor alone was 65c. per ton; in the new mill, the cost will be less than 20c. Mr. Sherman says the new mill will be completed and in operation by the middle of September, and there is every reason to believe that such will be the case, judging from the rapid progress being made at this time.

The Daly West mine is credited with a total production of $9,605,429, from which dividends to the amount of $2,925,000 have been paid.

A Barite Deposit Near Wrangell, Alaska*

By ERNEST F. BURCHARD

An interesting deposit of barite or 'heavy spar' was discovered while I was searching for beds of marble in southeast Alaska in September, 1913. This barite is situated on one of the Castle islands in Duncan canal, a long, narrow, shallow bay that extends northward into Kupreanof island from Sumner strait. The Castle islands, which consist of a group of six or seven islets ranging from 600 ft. to a mile in length, are about seven miles northwest of Beecher pass, one of the entrances to Duncan canal. Duncan canal lies three to ten miles west of the well known Wrangell Narrows, and the barite deposit, measured *via* navigable waterway, is about 40 miles northwest of the town of Wrangell. The nearest port is Petersburg, at the north end of Wrangell Narrows, about 25 miles distant.

There is little in the appearance of the deposit to suggest that it is other than a cliff of weather-beaten, fractured limestone, and it is probable that fishermen have sailed past it or have anchored their boats in its lee for generations, never suspecting that it is composed almost wholly of barium sulphate, a very useful mineral, but one much less common than calcite, quartz, or other minerals that make up the bulk of rock masses.

The deposit of barite forms a rocky outlier on the east side of the second island of the group, beginning at the southeast. It is shown in the picture at the top of the page, as the heavily wooded islet in the centre. The mass stands as block connected with the rest of the island by a low, narrow neck, about 200 ft. long, that is covered by water to a depth of 5 to 10 ft. at high tide. The top of this barite outlier stands about 35 ft. above high-tide level. The mass as exposed is roughly elliptical in shape, with its major axis extending in a direction about N. 30° W., and is possibly 75 ft. wide by 200 ft. long at the maximum. What its extent below low water may be would be difficult of determination, and its thickness measured perpendicular to the lamination is uncertain, but it is probably not less than 140 ft. Near the southeast extremity, which is narrow and more pointed than the northwest end, erosion has cut a notch in the deposit down to within a few feet of high-tide level. Below the base of the cliff, which is washed by extreme high tides, the beach slopes away in all directions and at low tide is 30 to 50 ft. wide with the water level some 15 ft. lower than the base of the cliff. All that is visible of this cliff and the surrounding beach, except the narrow neck which connects the outlier with the island, is of barite, either in place or as a talus deposit. A rough calculation, based on measurements by pacing, indicates that there should be more than 50,000 short tons of barite available above high-tide level.

Neither the appearance of the mass nor its geologic relations and structure offer very clear suggestions as to its nature or origin, but it is thought that it may represent the residual portion of a large vein or lens of barite, extending parallel to the schistosity of the adjacent rock, and representing the result of replacement of limestone by barite.

The barite is very much jointed, and is so fractured at the surface, probably by the action of frost, that the material tends to break into fragments not more than three or four inches in thickness. The beds strike N. 30° W. and dip steeply toward the northeast. Only barite is visible around the shore line of the outlier except on the southwest side facing the island where, at low tide, the contact of a granular schistose rock with the barite is just visible. The schistose rock strikes N. 30° W. and dips steeply northeast, just as does the barite. The neck connecting the barite outlier with the rest of the island is of schistose material, which becomes finer-grained and more thinly laminated toward the main part of the island. The island itself is composed mainly of schist.

The nearest islet toward the southeast, about 1000 ft.

*Published by permission of the Director of the U. S. Geological Survey. For more extended data, see U. S. Geol. Survey *Bull.* No. 592-D.

distant from the barite deposit and nearly in strike with it, is composed wholly of schist, and the next islet toward the northwest at a less distance is composed mainly of schist with some cherty limestone and veins of calcite. No other deposit of barite was observed, but

CLIFF OF BARITE ON CASTLE ISLAND.

the similar appearance of other cliffs on islands in the Castle group farther north, as observed through a field-glass, suggests the possibility of other deposits.

The schistose rock adjacent to the barite, and apparently dipping below it, is gray in color, granular in texture, crumpled to a slight extent, much jointed, and the grains have been flattened to a lens-shaped section. A thin section of this rock shows under the microscope the following minerals, all of which are regarded as secondary: chert, quartz, barite, a little plagioclase feldspar, a little mica, sulphides, and titanite. When treated with dilute hydrochloric acid it emits an odor of hydrogen sulphide, but does not liberate carbon dioxide.

The barite, where fresh, is mostly finely crystalline, grayish white rock with thin, grayish blue veins and clouded areas, and a few thin black streaks. Occasionally there is some barite that is coarsely crystalline and white in color, and there is some white quartz present in thin seams and small segregations. Pyrite is nearly everywhere present in fine specks disseminated through the mass or arranged in rough parallelism with the grayish blue veins in the rock. The thin black streaks are segregations of fine specks of dark minerals among which are probably galena, sphalerite, magnetite, and graphite. At the surface the material is strongly stained with iron rust resulting from the weathering of the iron pyrite.

Thin sections of the barite appear under the microscope to contain titanite, in part leucoxene derived from ilmenite, iron oxides, and metallic sulphides. The powdered material examined under the microscope showed, in addition to barite quartz, sphalerite (?), magnetite, and metallic sulphides. The thin sections show the barite crystals to have been strained and granulated, and probably the barite was metamorphosed along with the bordering schist. The pyrite crystals appear to be secondary to the barite. The powdered barite is grayish white in color, and under a hand lens shows many particles of metallic sulphides. Laboratory experiments, outlined on another page, suggest that with proper mechanical manipulation it may be possible to bleach the material on a commercial scale.

The presence of metallic sulphides in abundance warranted having assays made for the precious metals, and an average sample weighing about 50 lb. was collected from the surface of the deposit. According to the results of the assays, metals are not present in sufficient quantity to permit the barite to be classed as a metalliferous ore, and its commercial value consequently will depend on the quality and marketable value of the barite itself.

The following results were obtained from two independent assays of the material:

	Assayer	
	Burlingame.*	Ledoux & Co.†
Gold, oz.	0.03	0.010
Silver, oz.	0.79	1.05
Copper, %	0.05	0.07
Lead, %	none	0.29
Zinc, %	1.27	1.14

*Denver, Colorado. †New York City.

The results of a quantitative chemical analysis by W. C. Wheeler, of the U. S. Geological Survey, are as follows:

	Original, %.	Recalculated, %.
Silica (SiO_2)	5.05	5.05
Iron oxide (Fe_2O_3)	0.77	0.77
Titanium oxide (TiO_2)	none	none
Calcium oxide (CaO)	trace	trace
Magnesium oxide (MgO)	trace	trace
Barium oxide (BaO)	58.60	58.60
Strontium oxide (SrO)	0.37	0.37
Sulphur trioxide (SO_3)	34.74	33.69
Carbon dioxide (CO_2)	none	none
Lead oxide (PbO)	0.15	....
Lead sulphide (PbS)	....	0.16
Zinc sulphide (ZnS)	....	1.68
Manganese dioxide (MnO_2)	trace	trace
Total	99.68	100.32

In the original analysis there was shown a surplus of sulphur trioxide and the quantity of zinc sulphide was not determined, but its percentage was calculated as the equivalent of 1.27% of zinc as determined by the first assay. In like manner the percentage of lead sulphide was calculated by combining 0.15% of lead oxide, which was found by analysis with a sufficient quantity of sulphur trioxide to form lead sulphide.

According to this analysis the material contains about 89.16% of barium sulphate, or barite, and is therefore a little less than 90% pure. The chief impurity is silica, and for many purposes for which barite is used, a moderate percentage of silica, which grinds white, is not especially deleterious, nor is the strontia, which is in

too small quantity to be separated. The remaining minerals, which are mainly metallic oxides and sulphides, must aggregate less than 4.5%. Only about 2.61% are shown by the analysis. This is not a high percentage of objectionable impurity, and probably is below that carried by shipments of raw barite from many mines.

Mineralogy and Occurrence of Barite

Barite (also termed barytes), or heavy spar, is barium sulphate, the chemical formula of which is $BaSO_4$. The recorded occurrences of barite indicate that it is a mineral of aqueous origin and that it has formed as a direct deposit from waters or as a precipitate when waters of a certain composition mingled.[1] The pure mineral is composed of barium monoxide (baryta, BaO), 65.7%, and sulphur trioxide (SO_3), 34.3%. The specific gravity is 4.3 to 4.6; the hardness of 2.5 to 3.5. Barite is usually a white, opaque to translucent crystalline material, generally a little softer than calcite but harder than gypsum. It differs from both gypsum and calcite in its greater specific gravity, and by the fact that it is practically not affected by acids. A common form of the mineral is an aggregate of straight or slightly curved cleavable plates, but it occurs also in granular, fibrous, and earthy masses, in the form of stalactites and concretions, as well as in single and clustered crystals. Natural deposits of barite are rarely wholly pure, the most common impurities being silica, fluorite, lime, magnesia, and the oxides of iron, manganese, and alumina. The reddish and yellow stains which are characteristic of much of the commercial barite when freshly mined are due in large part to iron oxide. Fine crystals of galena and sphalerite are often found either disseminated in, or segregated through, the barite.

Barite occurs in veins in both sedimentary and igneous rocks as a gangue of metallic ores and also in veins where it is the predominant mineral. It occurs also as a cement between the grains of sandstone, as a replacement of limestone, as concretions in shale, and as a sinter deposited by springs. The deposits in the United States which at present supply the greater part of the output are in southeastern Missouri and in the Appalachian valleys of Georgia, North Carolina, Tennessee, and Virginia, where it is found generally in cherty and gravelly clay, residual from limestone, dolomite, and quartzite. Kentucky has vein deposits which are little developed.

Barite resembling the Castle Islands barite in having a granular crystalline texture, but a whiter color, has been found in the mountains about 12 miles west of Hailey, Idaho, north of Deer creek, according to L. G. Westgate, who reports that the deposit is in the nature of a vein which may be as thick as 200 ft., but which cannot be traced far on the strike. This deposit is associated with calcareous sandstones of Pennsylvanian age.

[1]Clarke, F. W., 'The Data of Geochemistry,' U. S. Geol. Survey *Bull.* 491 (1911), p. 555.

Uses and Preparation of Barite

Barite is used principally as a pigment in mixed paints, and in the manufacture of lithopone, a white pigment, but there are many other uses for minor quantities of barite, such as the manufacture of barium salts, which have a wide chemical application, the manufacture of rubber, wall paper, asbestos cement, artificial ivory, enamels, and for covering packages of ham, cheese, and other foods.

The value of barite as a pigment, if not used in excess in mixed paints, is due to its whiteness, its weight, and its inertness in the presence of chemically active substances, and also to its aptitude to take color stain uniformly, and to make a small quantity of color, such as aniline, cover much surface. In order that the barite may be suitable for the uses above mentioned, it must be free from all associated minerals which do not grind white, or which are affected by acids or atmospheric gases. Thus iron oxide, and the sulphides of metals, such as iron, lead, zinc, and copper must be removed, and there must be little lime or magnesia present. The presence of small percentages of clear or white quartz are not objectionable, for it grinds to a white powder and is not chemically active.

In preparation of barite for the market in the mining regions of Missouri, where the largest quantities are at present produced, the ore is first allowed to stand in the sun and rain so that much of the residual clay with which it is associated drops off, and hand cobbing, picking, and sorting results in such further cleaning of the material that it is ready for shipment to the mills. The product from some workings in the southern Appalachian region is first washed in log washers to free it of associated clay. Next the barite is separated into two or three grades by hand sorting, after which it is ready for the milling process. (Neither of these preliminary processes would be needed for the Alaska barite herein described, as it would be ready for milling directly upon being quarried.) Barite is milled by both the dry and the wet process. The wet process is the later and more effective one, and the one now most generally employed. Several types of mills are in use. The milling processes consist of crushing, grinding, washing, bleaching, and drying, although not necessarily in the order given. The most troublesome impurities seem to be galena and limonite. Where the galena occurs disseminated in fine grains through the barite, the two minerals are not easily separated by jigging or flotation. The limonite cannot be entirely removed by ordinary jigging, and magnetic separation has been attempted but not yet accomplished. Bleaching with sulphuric acid, however, removes the iron if it is not present in quantity so great as to require an excessive amount of acid, but does not so readily affect the lead compound, which, when ground with the barite, imparts a grayish tint to the material, and thereby reduces its value as a pigment. Lime carbonate is also a deleterious impurity when it occurs in sufficient quantity to neutral-

ize a portion of the acid which is used in the bleaching process.

In the manufacture of the white pigment, lithopone, an intimate mixture of precipitated zinc sulphide and barium sulphate, barite is first reduced from the sulphate to the sulphide of barium, which is soluble, and then treated with a solution of zinc sulphate. The reduction of barite is effected by heating to bright redness a mixture of about four parts of crude barite and one part of a very low ash coal in a rotating furnace. The coal acts as a reducing agent, and converts 60 to 70% of the barite to barium sulphide, the remainder being converted to barium carbonate. A similar principle is employed in the initial stages of the production of other barium salts.

Possible Value of the Castle Islands Barite

The grade of the barite described above is not of the highest, particularly for use as a pigment, and it will probably require a milling test to determine whether or not it may be possible commercially to remove the metallic sulphides and to bleach the color to a pure white. Simple laboratory experiments and comparison of the Alaska material with commercial grades of barite suggest that this may be possible. For example, tests by W. C. Wheeler and myself show that washing and flotation tend to whiten the finely ground grayish white powder. Further treatment with hot dilute sulphuric acid containing small quantities of sodium chloride and sodium nitrate bleaches the powder to a shade only slightly less white than that of precipitated barium sulphate or zinc oxide. These experiments are encouraging and seem to indicate that with the aid of proper mechanical manipulation the process might be made commercially successful.

In the process of manufacture of lithopone and the various salts of barium where crude barite is fused with coal a slightly impure raw material would apparently react as well as one having a high degree of purity, providing the impurities present were not in themselves objectionable. It is possible, therefore, that the Alaska barite is suitable for general chemical purposes. Probably it would not be practicable to build and operate a barite mill in the vicinity of the deposit, but the raw material can certainly be quarried and loaded on barges very cheaply, and transported to Puget sound or to San Francisco at low freight rates. The approaches to the Castle islands, while not very deep, show according to the Coast and Geodetic Survey charts from 5 to more than 30 fathoms of water. In the immediate vicinity of the islands the depth of the water is such that wharves could be built, and there is plenty of timber at hand suitable for this purpose. There is level space on the island of which the barite deposit is an outlier sufficient for the necessary buildings of a quarry camp. Quarrying of the deposit would evidently be very simple, as the material could be blasted from the face of the cliff and a large output obtained in a relatively short time. Over the top of the mass there is a brushy growth of spruce and cedar with but little soil, and if this were stripped off at first the deposit would afford an unusually clean quarry.

Production, Imports, and Prices of Barite

The production of crude barite in the United States in 1913 was 45,298 short tons, valued at $156,275. This represents the value of the crude material f.o.b. mines and gives an average price for the whole country of $3.45 per ton of 2000 lb. The average price in the southeast Missouri district was $3.78 per ton. The imports of crude barite entered for consumption during 1913 amounted to 35,840 short tons, valued at $61,409, or $1.71 per ton, and of manufactured barite amounted to 4463 short tons, valued at $38,155, or $6.98 per ton. Of these imports, 82 short tons of crude barite, valued at $144, or $1.76 per ton, and 601 short tons of manufactured barite, valued at $3976, or $6.62 per ton, were entered at San Francisco.

Electric Power at the Homestake

By JESSE SIMMONS

At the Spearfish hydro-electric installation of the Homestake Mining Co., in South Dakota, 40 to 120 cu. ft. of water per minute, depending on the stage of the stream, is carried through 23,862 ft. of tunnel, 1200 ft. of 48-in. redwood stave pipe, and 12,164 ft. of steel-pressure pipe. The wood pipe is laid in two lines, and the steel pipe in three lines. The steel pipe is of 34, 32, and 30-in. diameter; the smallest size being $\frac{7}{16}$ in. thick. Expansion joints and anchors to prevent pipe creeping down hill are spaced about 250 ft. apart. The head is 665 ft., giving a working pressure at the wheels of 288 pounds.

The transmission line of the hydro-electric installation is 11 miles long from the Spearfish generating station to the Lead distributing station. Cedar poles, with an average span of 134 ft., carry on two cross-arms two complete three-wire circuits; one being sufficient to carry the load, the second is kept in reserve. No. 2 hard-drawn copper wire carries the current; on top of the poles is a No. 4 copper-clad ground wire; below the cross-arms are two No. 12 copper-clad wires, forming a telephone circuit. The power is transmitted at 33,000 volts.

Electricity is used for stage pumping of the mine water at the B. & M. shaft. Jeansville double-suction, three-stage pumps, with a capacity of 1000 gal. per minute against a head of 315 ft., are each driven by 125-hp., 2300-volt, A.C. motors. Three auxiliary pumps, of 500-gal. capacity, are driven by 75-hp. motors. Water is lifted in 300-ft. stages, discharging into large concrete-lined sumps, across the top of which are I-beams to which the pumps and motors are bolted.

Electricity is used to drive all of the stamps and rock-crushers, a pumping system at the B. & M. shaft, and numerous other incidental machinery.

Length of Service of Calumet & Hecla Miners

Indicative of the length of service of employees of the Calumet & Hecla, it is interesting to know that this Company employs over 400 men who have been working from 15 to 20 years for this concern, and who have 31 sons working for the Company; 427 began between 20 and 25 years ago and have 62 sons working now; 433 began between 25 and 30 years ago and have 90 sons working now; 174 began working between 30 and 35 years ago and now have 59 sons working; 112 of the present employees began working for the Calumet & Hecla between 35 and 40 years ago and have 44 sons working; 111 began working over 40 years ago and have 57 sons working now. This makes a total of 1660 men who have been working for the Calumet & Hecla company between 15 and 45 years, and they are working at the present time. They have 344 sons working, or a total of 2004.

Improvements at the Ohio Mill, Lark, Utah

The coarse-crushing unit is now in operation and giving excellent results at the concentrating plant of the Ohio Copper Co., according to George F. Waddell, the general manager. The plant consists of one mill proper, in which the ore is crushed and all treatment carried out, except the concentration of the fine slime, which is treated in a separate building known as the slime plant. Both buildings are of steel construction.

The ore is received in cars of five-ton capacity from the mine, approximately 3½ miles distant, by electric haulage through the Mascotte tunnel. One of the steel pan-conveyors, 36 in. wide and about 100 ft. long, delivers the ore from apron feeders under the coarse bins to one grizzly, the oversize of which is reduced to 2-in. pieces in a 24-in. Blake crusher. This product, together with that of the grizzly, passes to one set of 24 by 64-in. Garfield type rolls, where it is reduced to ¾ in., being delivered from there to an elevator, on which it is conveyed to the screens, where a ¼-in. undersize is obtained. The oversize passes to one set of coarse rolls and one set of fine rolls. These rolls discharge to the same elevator as the first rolls, thence to the screens mentioned, thus forming a closed circuit, with the screens as the outlet for the final product. Another steel pan-conveyor will be installed to accommodate the other bin, although the steel pan-conveyor in operation at present is handling the entire tonnage.

The 24-in. belt-conveyor, 70 ft. long, and reversible in its delivery, for the purpose of accommodating three fine-ore bins having each a capacity of 300 tons, and built at the head of each mill unit, has been installed. This conveyor serves two of the bins directly, and when the other 24-in. conveyor, to serve the third bin, is installed the first conveyor mentioned will deliver to it.

From the fine bins at the head of each section the ore is fed by Challenge feeders in a dry state to two 18-in. elevators, each of which discharges to four impact screens, making approximately a 2-mm. undersize. The oversize passes to four sets of 15 by 36-in. rolls. There are two sets for each elevator, and they crush to 2-mm., discharging to the two elevators mentioned and thus making a closed circuit of the operation. From this point in the operation no changes have as yet been made in the flow-sheet, although these are under consideration.—*Salt Lake Tribune.*

Atomic Weights for 1915

The Council of the International Association of Chemical Societies, with which the Committee on Atomic Weights is now affiliated, recommended, at its meeting in September 1913, that the annual report of said Committee should be published in August. The present report is submitted in compliance with that recommendation and contains the weights for 1915 as reported in the *Jour.* Amer. Chem. Society.

	Atomic weight.		Atomic weight.
Aluminum (Al)	27.1	Molybdenum (Mo)	96.0
Antimony (Sb)	120.2	Neodymium (Nd)	144.3
Argon (A)	39.88	Neon (Ne)	20.2
Arsenic (As)	74.96	Nickel (Ni)	58.68
Barium (Ba)	137.37	Niton (Nt)	222.4
Bismuth (Bi)	208.0	Nitrogen (N)	14.01
Boron (B)	11.0	Osmium (Os)	190.9

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply by Mr. Horwood to Mr. Draper's Discussion

In criticizing that portion of my paper which deals with the Witwatersrand syncline, D. Draper commences by misquoting me. I did not state "that the southern and western outcrops (of the syncline) are missing." I said that "the southern and southwestern boundaries are missing." However, had I only pointed out that the southwestern boundary was missing it might have more clearly expressed the meaning that I wished to convey, namely, that the syncline is not a basin but a valley trending northeast and southwest, with its mouth at the southwestern end, and consequently at that end no outcrops of the beds occur.

Mr. Draper suggests that I have ignored the Vredefort granite, and its surrounding sediments. There was no occasion for me to refer to it, as it is beyond the area with which my paper deals. He then makes the definite statement that "the evidence both on the Witwatersrand and in the Vredefort area points distinctly to great earth-movements, resulting in the formation of a synclinal trough *after* the Ventersdorp diabases had solidified." He brings forward no facts in support of this statement, except that the Witwatersrand beds flatten in dip toward the Ventersdorp diabase, whereas he maintains the reverse would have happened if volcanic matter had been removed from below them. It will therefore be sufficient to point out that simultaneously with the removal from below of molten rock, the latter was ascending through openings toward the surface, and consequently there would be a tendency for the dip of the subsiding sediments to be lessened in the immediate neighborhood of the uprising igneous rock. As regards his expression of personal opinion in relation to the Vredefort granite area, I do not agree with him, and in a paper by me entitled 'The Old Granites of the Transvaal and South and Central Africa,' to which A. Wade contributed a petrological description of the Orange Grove granite, I called attention to the fact that Molengraaff in 1903 had showed that this Vredefort granite mass was of much later date than the Witwatersrand beds, and later even than the Pretoria series, but earlier than the Karroo system.[1] This subject has recently been dealt with again by F. W. Penny.[2] The intrusion of this particular granite mass had nothing to do with the formation of the Witwatersrand syncline and doubtless occurred long after it had been formed.

Neither can I agree with his opinion that it will not be generally conceded that such intense volcanic activity could have produced numerous lateral fractures; as such cases are numerous. As an example, I would mention that Molengraaff showed that numerous dikes intersect the strata of the Transvaal system[3] all around the basin of the igneous complex of the Bushveld, as a consequence of the intrusion of the igneous rocks.[4]

Mr. Draper states that the igneous dikes associated with the Witwatersrand beds cannot be in any way connected with the Ventersdorp diabase, but again brings forward no facts to support this opinion, whereas I showed the great similarity in petrographical, physical, and chemical properties of the two rocks; and that the general structure of the district indicated that they are connected in origin in depth.

Mr. Draper suggests that because the Ventersdorp diabase is amygdaloidal, its source was probably many miles distant from the Witwatersrand, since it represents lava flows. He does not seem to realize that there is no chemical or physical reason why even a dike should not be amygdaloidal, provided the aqueous and other vapors which it contained were above the critical temperature at the time of its solidification. I had previously pointed out that an amygdaloidal dike occurs in the Saxon gold mine, and there is also an example in the Heidelberg district of such a dike to which G. S. Corstorphine called my attention.[5] I also pointed out that the axis of the synclinal basin of the Witwatersrand would naturally mark the line along which the main fracturing and resultant vents occur.

Mr. Draper then says that if my contentions were correct, surely there would also be numerous dikes crossing the strike of the beds when such a gigantic volcanic outburst occurred. Had he read my paper a little more carefully he would have realized that I particularly called attention to the presence of such transverse dikes, and showed that although somewhat younger than the longitudinal dikes, since they have in many cases faulted the latter, they also are, or at all events the majority, connected in depth with the same diabase magma.

I do not quite follow Mr. Draper when he speaks of the banket beds having been tilted into their present position after their solidification. Does he suggest that these sediments were ever in a molten or liquid state?

In support of his statement, he calls attention to the fact that strain phenomena is a marked feature in microscopic slides of the banket; undoubtedly it is, and this is a natural consequence of the pressure to which these beds have been subjected.

He agrees that I have shown conclusively that sometimes there is a decided rise in the gold content of the banket as a line of faulting is approached; but says I have not shown that a similar phenomenon occurs in the neighborhood of a dike except in the Crown Reef mine, where the dike is accompanied by an upthrow fault; and asks why I consider the dike channels rather than the fault lines as having formed deep seated communications for the up-rising mineral solutions. I consider the main structural lines of faulting as due to the fracturing and disturbance produced during the same period of eruptive activity to which the dikes are due; and consequently they also may have formed deep seated channels for the ascension of the mineralizers. The example I gave of enrichment near one of these main structural faults and which Mr. Draper quotes, should have made it clear to him that I hold this view. If Mr. Draper will read my paper carefully he will find I have given several instances of enrichment near dikes.

Mr. Draper also contends that the intrusion of basic igneous dikes being accompanied by the ascension of other than molten material will not be generally accepted by geologists. The simplest manner of dealing with this portion of his criticism is to refer him to the works of J. H. L. Vogt, S. Arrhenius, and J. F. Kemp, although it seems invidious to pick out particular authors among the numerous well known authorities on the genesis of ore deposits or on world structure.

Mr. Draper says that the fact that these dikes contain traces of gold may be accounted for by their having robbed the gold-bearing beds which they intersected. If he will describe to me the physical and chemical conditions under which such a transfer is likely to have occurred, I shall then have much pleasure in replying to this portion of his criticism.

He says that metamorphosis by basic dikes has rarely been recorded. I have recorded such metamorphism in my paper, which I would again ask him to peruse more carefully.

In the last paragraph of his discussion he states that his conclusions lead him to believe that the gold-bearing solutions were introduced into the Witwatersrand beds while the latter were in a porous condition, either by means of fissures or directly from the aqueous solutions in which the beds were formed. He then relates that a number of nuggets were found at the Rietfontein Mines, one of which weighed over 2 oz. and several over 1 oz. in weight, which were ordinary nuggets such as are found in alluvial gold-bearing deposits. I am really at rather a loss to understand how Mr. Draper reconciles these two statements.

London, June 1. C. B. Horwood.

Milling in Cyanide

The Editor:

Sir—Mr. Noel Cunningham's criticism of figures quoted by me is not unexpected, and I have to thank him for the interesting comparative details he now gives in the July 4 issue as to Dome and Hollinger practice. I may point out that the ones I used last year have been recently re-published, without correction or added comment, in Megraw's 'Details of Cyanide Practice'. It seems regrettable that such information is not revised by those who are chiefly interested and directly responsible.

While accepting Mr. Cunningham's more recent figures I am entirely unwilling to agree with him that they upset the contention I raised in my original article. The extraction at the Hollinger is now given as 96% and that of the Dome as 95%; but this shows no superiority in treatment method when allowance is made for the fact that the ore is three times richer at the Hollinger than at the Dome. Taken in conjunction with the amount of gold left in the residue the result is all in favor of Dome treatment.

Mr. Cunningham's assumption that the precipitation-ratio at the Dome could be reduced to 0.9 to 1 by abolishing amalgamation and adopting milling in cyanide is totally opposed to practice, being based on the faulty contention that such ratio must invariably be relative to the grade of the ore.

"On account of crushing in water" Mr. Cunningham adds, "an excess of solution is made and a corresponding amount must be precipitated and thrown away." I dealt with this aspect in the communication now commented upon, and said: "It is of course imperative that the equipment should be designed to dewater before cyaniding to within a few percentages of moisture contained in the discharged residue. If this is impossible then milling in water is either impracticable or inadvisable." A faulty detail or an omission in Dome practice may be condemned but this is no argument against the principles involved.

Mr. Cunningham states that I make a point in favor of 'waste' solution.. He is entirely in error because I am opposed to such practice. His subsequent remark that: "There is always a loss of solution in the tailing * * * sufficient to offset fouling," is merely a repetition and not a contradiction of what I have already enunciated in the *Press* as the simplest method of avoiding such trouble.

London, July 25. A. W. Allen.

Gold production of British Guiana has averaged 72,878 oz. per year for the past 10 years. The yields during 1912-13 from the several methods of operation were: placer washing, 38,472 oz.; dredging, 12,033 oz.; hydraulicking, 823 oz.; and quartz mining, 437 ounces.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE PREMIUM CHARGEABLE on each $480 of insurance, under the Western Australian Workers' Compensation Act, is $2.40.

STAMP-MILLING through coarse screens is generally followed by tube-milling. In this case it has been found a distinct advantage to crushing efficiency to adopt a battery screen of oblong opening. By this means the battery output will be increased with the addition of oblong particles of ore which are more easily pulverized in the tube-mill than cubes of similar volume.

COPPER for the Royal Mint, London, amounting to 200 tons, was required by tender on August 6. Ingots supplied must weigh between 14 and 18 lb. each, and be guaranteed to contain not less than 99.8% of copper, and not more than 0.005% lead, 0.005% tellurium and selenium taken together, 0.001% bismuth, 0.001% tin, 0.001% antimony, 0.01% iron, and 0.02% arsenic.

THE MATTE may be removed from the top of cyanide bullion by putting the bar into a large crucible in a hot fire, and when the matte melts, which will occur before the bullion reaches its melting point, the bar may be withdrawn from the crucible. It is often advisable to then remelt the bar, which may be quickly done in the same crucible after the matte has been poured into a suitable mold.

PNEUMATIC AUGERS are used in the Central mine, Broken Hill, according to James Hebbard in the *Compressed Air Magazine*, their principal work being in the repair of crushed timbered drifts and cross-cuts. In this operation, large quantities of old 10 by 10-in. Oregon pine legs and caps have to be removed, together with the decking, in restricted spaces where the use of axe or saw would be tedious at best, or almost impossible. The drills are also useful in various other minor jobs, such as for boring holes for hanging bolts in shaft sets, or for bolts for handrails at shafts and winzes. The tool used is the No. 11 Imperial piston drill, and the auger bit found most suitable is 1½ in. diameter. This is for Oregon pine; a smaller bit would doubtless be preferable for hard wood. The advantages of the pneumatic auger over axe or saw for cutting through heavy timbers in the confined limits of a narrow drive will be readily appreciated.

CYANIDE MILLMEN should make an effort at all times to turn out bullion with a low base-metal content. United States mint charges are computed at stated prices per ounce of bullion deposited; to give the mint a bar containing much base is only to pay a tariff on some valueless material. With zinc-shaving precipitation, there are two important features tending to yield clean bars. First, do not take any coarse zinc in cleaning-up. Take only the gold precipitate and the shortest zinc, preferably that which will, by working, drop through the screen in the bottom of the precipitating compartment. The next important factor is a painstaking wash, or several of them, if at all convenient, with hot water, after the acid treatment. Hot water means water as hot as live steam will make it. Use plenty, all the wash tank will hold. This is the only practicable means of eliminating the sulphates formed in acid treatment. A careful observance of these two hints will enable the operator to turn out clean bullion, saving mint charges and, furthermore, it will be bullion which will give uniform assays on samples taken from various parts of the bar.

COMPARISON of the Huntington-Heberlein and Dwight-Lloyd processes of sintering ores is discussed in the August *Bulletin* of the A. I. M. E. by W. W. Norton, of Murray, Utah, who summarizes his experience there as follows:

	Advantage in favor of
Cost of installation	D.-L.
Cost of roasting	H.-H.
Adaptability of charge	D.-L.
Metal losses	Doubtful
Physical condition of product	H.-H.

The D.-L. is a good modern machine now brought to a state of efficiency where it is splendidly adapted to lead-smelter work. The H.-H. process is still operated with a good measure of success. A good-sized compact H.-H. plant at Murray, well designed and operated in a painstaking manner, permits of possibly an unusually good expression being recorded in favor of the H.-H. The low first cost of D.-L. units, and the ease and flexibility with which successive units may be added to any given lead smelter, are perhaps the reasons why a greater number of 400-ton H.-H. plants have not received thorough trial. Actual experience with D.-L. machines at Murray has caused them to gradually grow in favor from year to year. The operators are highly pleased with the flexibility of charge and other important items. The well sintered product is so good as to make it unfortunate that exaggerated claims for its virtues should have been published. Mr. Norton was unable to point out any overwhelming advantage of the D.-L. over the H.-H. system, although continued progress may upset the balance at any time. If history repeats itself, some new roasting system will take rank over both within a few years.

REVIEW OF MINING

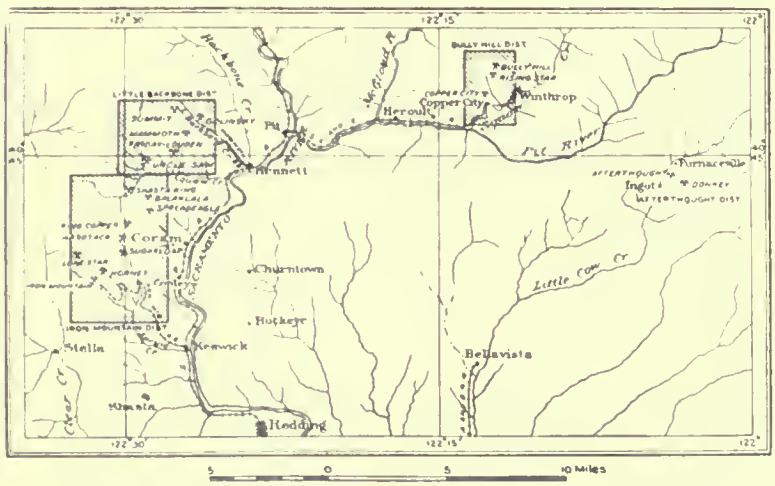
As seen at the world's great mining centres by our own correspondents.

HEROULT, CALIFORNIA

FERRO-MANGANESE TO BE MADE AT HEROULT.—EUROPEAN WAR AFFORDS OPPORTUNITY TO ESTABLISH NEW INDUSTRY.—FURNACES BEING PREPARED.

Although the European war has temporarily disturbed California's mining industry in general, it has also been the cause of establishing an entirely new branch of mining and metallurgical operations in this state. The trouble in Europe has greatly disturbed Shasta county mining through the temporary shutting down of several of its copper mines, the largest of which are the Iron Mountain property at Keswick and the Balaklala property at Kimberly. The electric furnaces of the Noble Electric Steel Co., however, are about to start the commercial production of ferro-manganese at Heroult. The electric steel industry at Heroult was stopped several months ago, due to the fact that the type of furnace which had been adopted for this purpose was not able to produce steel in competition with the Eastern market. Since the shut-down, J. C. Crawford, Jr., manager, has been carrying on a set of experiments along the lines of the production of ferro-alloys with the aid of a small three-phase arc furnace which was constructed for experimental purposes. Ferro-alloys have been successfully produced by this furnace for some time, but it is due to the sudden change in the ferro-manganese market that the large furnaces at Heroult will be rebuilt with the intention of producing this metal on a commercial basis. Mr. Crawford says that "the price of ferro-manganese since the outbreak of war in Europe has jumped from $38 per ton for an iron-manganese alloy containing 80% manganese to as high as $150 per ton, and while the receipts of certain consignments which are en route from England have steadied the price somewhat, the steel trade papers under date of August 20 quote it at from $100 to $125 per ton, Atlantic seaboard. In anticipation of such a condition arising, the Company has recently made arrangements to manufacture ferro-manganese. It has secured control of what is considered one of the highest grade and largest deposits of manganese ore in the state, and will immediately take the necessary steps toward getting ore out to a railroad point, four miles distant, for shipment. The Company is considering offers from owners of manganese ore for immediate shipments. Ferro-manganese is the one alloy that is universally used for the manufacture of all steel, no matter by what process. Its virtue is twofold. It acts as a deoxidizer and cleanser to remove dissolved oxides and oxygen which are deleterious to steel, and in addition to this it imparts to steel properties of hardness, toughness, and resistance to abrasive wear which is required of all steel products. This country has relied almost entirely on England and Germany for its supply of the high 80% grade which is most in demand. That this country has not manufactured ferro-manganese of high grade to any extent has been due to the fact that the main source of high-grade manganese ore which could be cheaply delivered has been parts of Asiatic Russia and India, though Brazil also contributes a considerable amount, as does Spain.

"In the state of California are a great many manganese deposits, several of which are of considerable extent and of good grade, but inability to meet foreign transportation costs has caused these properties to remain idle. It has long been the desire of the Noble Electric Steel Co. to enter the field of making ferro-alloys of manganese and chromium, and now the opportunity has certainly presented itself. Our furnaces are admirably suited for the purpose, as metallurgical details of making ferro-manganese are similar to those in making pig iron. The cost of making ferro-manganese, however, is considerably greater than of making pig iron, but there will be a very substantial profit in making the former, even at a price very much lower than that at present existing. The Company is cleaning and making ready one furnace to be put in commission as soon as the shipments of manganese ore start to arrive, and it seems very likely that conditions will justify the placing of the second furnace in commission shortly afterward. In addition to the eastern market afforded by steel works and iron foundries, Japan is a large consumer, and an appreciable amount is also used by the steel works and foundries of the Pacific Coast.



MAP SHOWING SITUATION OF HEROULT, SHASTA COUNTY, CALIFORNIA.

"Though it is reported that English manufacturers will endeavor to resume shipments of ferro-manganese inside of 60 days they are now asking $102.50 c.i.f. Atlantic seaboard, for future shipments, which were not contracted for previous to the war, and they are only agreeing to fill contracts already made, on consideration of good advances over contract prices to cover the extra insurance risk. It is generally understood that there is at the present time only sufficient ferro-manganese and manganese ore in England to supply the demand for four or five months and as future supplies of ore from Russia, India, and Spain are very uncertain it is conceded that the price of ferro-manganese will remain high for a considerable time to come and those who have supplies of ferro-manganese are finding no difficulty in securing contracts at very favorable prices and for the coming year.

"In making ferro-manganese the Company will use a mixture of half charcoal and half coke. Arrangements have been made for an immediate supply of charcoal and to secure the necessary oak wood to make the charcoal later. The date of starting up depends on arrivals of manganese ore and getting together a furnace crew, but it is believed that the plant can get started in about two weeks."

HOUGHTON, MICHIGAN

SUMMARY OF THE COPPER MINING INDUSTRY OF THE LAKE SUPERIOR DISTRICT.—EFFICIENCY SYSTEMS STARTED.

There is a general impression throughout the country that the Lake Superior copper country is now passing through the last days of its history. The reasons for this belief appear to be that (1) the mines have reached such great depths; (2) with the decrease in copper content of the 'rock' at lower depths, mining is possible only at a small profit; and (3) the district has not recovered, and probably will not fully recover, from the strike recently carried on by the Western Federation of Miners. A clearer comprehension of the true conditions may be had from a somewhat brief and general review of the history of the district from the time immediately preceding the strike to the present. Whether the copper content of the rock decreases with depth has not been definitely proved, but that is a point which will have to be seriously considered when the state tax commission arrives here. When the first general strike in this district was called on July 23, 1913, by the Western Federation of Miners, the number of men employed on surface and underground at the various mines totaled 14,250. Within a day practically every mine in the district was closed, and every man employed was deprived of his work. It has been estimated that at that time the various mines were operating with about 1500 men short of normal force. As soon as it was safe and possible under the then existing conditions, the companies renewed operations with small forces. From that time the number of men employed increased as fast as they were needed until on October 8, 1913, there were 5445 men working, and of these 2079 were underground. By the first of the year most of the big producers were back to normal production. April 12, 1914, marked the official end of the strike, when a general vote taken throughout the district expressed the desire of the majority of men to return to work. Following the vote, there was a rush of the men to the mines seeking their old positions. Idle properties were reopened, forces increased as soon as possible, and the old spirit of satisfaction and good times again prevailed among the men. On July 23, 1914, one year after the Western Federation strike was called, the same mines had in their employ 16,505 men, an increase of 2255. The number of men employed in smaller exploration properties and those in the mines not included in the above brought the total up to 17,205. This was the largest number of men ever employed in the copper country. Not only was the total payroll higher than at any time previously in the history of the district, but the average individual pay check was larger than ever before. The payroll of the mining companies in July amounted to about $1,341,990. It has been said that the Lake Superior copper district is the richest in the world. However, the study of the dividends and assessments of about 70 mining companies which have operated in the district from 1849 to 1910, show that of the entire number, only 14 have paid back the money invested. If the Calumet & Hecla be omitted, the industry has just about paid back the money invested in it. Indeed it is remarkable that it should be a profitable one. The ore mined in Michigan is of lower grade than that of any other district, the average copper content per ton of rock mined is about 20 lb. This ore is mined, hoisted, crushed, transported to mills, stamped and concentrated, and the concentrate transported to smelters, there to be smelted and refined. The final product, after being transported to eastern markets, is sold for about 14c. per pound. The low margin of profit, the increasing depth of the mines, and the lower grade of the ore have made it necessary for the operators to study closely cheaper methods of mining, handling, and treating the ore. It is the steady improvement along these lines that explains the fact that the Michigan copper district was in July 1914 approaching the greatest production in the history of the district.

Technical graduates are now employed in the larger mines as 'efficiency' engineers. It is the duty of these men to improve underground practice by instructing the miners in the use and care of drilling machines, and by studying and comparing the costs of different methods of mining and handling the ore. One important result of this efficiency work has been the almost general adoption of the one-man drill. The type of machine first used was the Leyner-Ingersoll, which weighs about 150 lb. Recently the Quincy Mining Co. supplanted its old drills with the new 'Baby Leyner,' a 90-lb. one-man drill. This new drill is not only lighter, but is dustless and easily handled and operated. The output of the mines is thus increased, and the miners are receiving higher wages.

All credit is due to the Calumet & Hecla for its initiative in the introduction of efficiency methods. About five years ago its No. 1 regrinding plant at Lake Linden went into operation. This plant was built to regrind and recover more copper from the tailing of the Calumet mill. That this mill shows an average profit of over $150,000 per year certainly proves the success of this venture. A second regrinding plant is nearly completed, a portion being already in operation and handling the tailing of the Hecla mill, which has been going into the lake as waste. The remaining part of this No. 2 plant when completed will treat the enormous tonnage of C. & H. stamp sand along the shore of Torch lake. This product has been accumulating for nearly 50 years and there is now over 40,000,000 tons that can be reground. While the erection of these regrinding plants were steps far beyond the hopes of the people of the copper country, a third large concentrating plant is now in the process of construction. This new plant will re-treat all the sand and slime of the two regrinding mills by a leaching process. It is estimated that a recovery of 70% will be made of the copper contained in the product of the regrinding mills. There is over 40,000,000 tons of sand to be reground and treated, which will average about 15 lb. of copper per ton. The regrinding mills should recover from 5 to 6 lb., and the leaching process 70% of the remainder. The president of the Company states that the new leaching process indicates that the extractable value of the conglomerate sand will be $20,000,000. The large electric dredge, which will recover the sand from the lake and clean it on its way to the regrinding mill, is almost ready for operation.

MELBOURNE, AUSTRALIA

MANUFACTURE OF CEMENT.—IMPORTATION OF PYRITE.—BROKEN HILL PROPRIETARY FINANCE.

A company has been formed in Queensland for the working of large limestone deposits near Gore, in the Stanthorpe district. The works will be established at Darra, about ten miles out of Brisbane, where there are suitable clays and shales in a ridge from 27 to 50 ft. high along the railway, entailing only 'face' working. These shales have been reported on by B. Dunstan, the government geologist of Queensland, as follows: "The shales contain varying percentages of iron, silica, and alumina, and the quantities are practically inexhaustible. They are eminently suited for the manufacture of cement, on account of the varying amounts of the essential ingredients, alumina, and silica, together with the presence of iron in some of the beds of shale. The Gore limestones and the Darra shales would make a perfect combination for the manufacture of portland cement." The Darra property consists of sixty acres.

As regards the Gore deposits, which cover an area of 44 acres, 3½ miles from a railway, Mr. Dunstan said: "The rocks in the locality are slates, limestones, and quartzites, which all appear to be regularly bedded, the slates extending over a large area of country, the limestones and quartzites forming

long narrow parallel belts alternating with the slates. The strike is northeast and southeast, the outcrops occurring at places in both directions for miles. The quality of the stone at Gore is exceptionally good. It is very compact, and is practically free from iron, alumina, and magnesia, and no hesitation need be felt about its suitability in the manufacture of cement of the highest standard."

Coal and water is available close at hand, and the cost of getting the latter is estimated at $16,000.

The cost of production of the estimated 30,000 tons of manufactured cement is as follows:

Limestone delivered at plant	£24,300
Coal	5,625
Clay and shale	1,500
Repairs, lubrication, etc	1,500
Labor and laboratory expenses	8,250
Bags (not allowing for returns)	9,000
Management, general expenses, and depreciation	6,250
Total	£56,425

Freight is estimated at 60c. per ton additional, bringing the total up to $9.72 at Brisbane. The Company is, however, in possession of a guarantee from a prominent firm of engineers, agents for a European cement-machinery manufacturing firm, to manufacture standard cement from the available material at a maximum cost of $8.50 at the works or $9.10 in Brisbane.

An application has been made to the New South Wales Mines Department for the imposition of a protective duty of $2.43 per ton on pyrite, and $1.85 per ton on sulphur mined in the interests of a company working a deposit in the Mount Stewart mine near Craborn. Much of the ore, which is well fitted for use in the manufacture of sulphuric acid, contains 46 to 51% sulphur and 41% iron. The importation of Spanish pyrite for the making of sulphuric acid amounted last year to 12,835 tons, valued at over $137,000.

An issue of debentures amounting to $3,000,000, as a first instalment of $5,000,000, to help carry out the Broken Hill Proprietary's scheme of iron and steel manufacture, was a success in every way. So far, between $3,000,000 and $3,500,000 has been spent on the new plant at Newcastle, New South Wales.

KALGOORLIE, WESTERN AUSTRALIA

LABOR TROUBLES IN THE STATE; UNIONISTS FIGHT CONTRACT WORK ALTHOUGH HIGHLY PAID.—HORSE-SHOE, EDNA MAY, AND LANCEFIELD MINES.—GOLD RETURNS AND ORE RESERVES.

Labor unrest here, as elsewhere, still continues, and although men on the Trans-Australian railroad at Kalgoorlie, and in the building trade at Perth, have returned to work, they seem far from satisfied, and may strike again any time. The miners at the Golden Ridge, 12 miles east of Boulder, and at Leonora, have appealed to the Arbitration Court for a revision of wages on a higher scale. The Yuanmi mine is shut down, because the majority of the men led by an outside agitator refused to continue to work with 12 men sinking by contract, although H. G. Walton, the manager, proved that the wages earned by the contractors during five months had ranged from $4.06 to $10.26 per 8-hour shift per fortnight, and had averaged $6.10. The men insisted on expelling the 12 delinquents from their union, with the result that the mine is shut down, and, as it is a one-mine town, the hotels, stores, etc., are doing nothing. As the mine is miles from anywhere, work is not likely to be resumed for some time, as the oxidized ore is depleted.

Monthly operations at the Horse-Shoe now show a profit of $12,400 against a loss of $17,000 per month for the preceding four months, while the grade of ore has improved from $5.20 to $5.76 per ton. On December 31 the assay value of the ore reserves was given officially as $7.28, the same as the previous year. At 2900 ft. in the main shaft, No. 4 lode shows considerable improvement; 15 ft. assaying $18.36 per ton. The lode shows telluride and fine gold. This is the Boulder main lode which passed into the Horse-Shoe at 2630 ft. and has produced the bulk of the Boulder's production of 2,509,600 tons returning $45,958,000.

Since it was taken in hand 18 months ago, the Edna May mine at Westonia, 42 miles west of Southern Cross, has produced 19,300 tons of ore for $404,900 and paid $171,400 in dividends. Untreated residue is estimated to contain $100,000 and a profit of $72,500. The lode on this property was found after sinking a shaft to 75 ft. and then cross-cutting. After proving the ore-shoot to be 215 ft. long, and from 8 ft. to 44 ft. wide, a raise was driven which proved that the lode cut off 17 ft. from the surface, above which was an overburden of 'cement' and loam. Two years prior to this discovery the lode in the adjoining lease, worked by the Greenfinch company, had been cut off at a depth of 90 ft. by successive granitic intrusions. At the 150-ft. level in the Edna May mine, a flat granite bar similar to those on the Greenfinch, and 8 in. thick, crosses the lode, but the ore-shoot maintains its length, width, and gold content below the bar. The main shaft is down 232 ft., where the inflow of water has increased from 2000 at 150 ft. to 3500 gal. per hour. The lode is in the shape of a horse-shoe, and is a geological freak, and has puzzled all the geologists who have examined it. A year ago the ore reserves above the 75-ft. level were 20,000 tons worth $20.40 per ton, and are now estimated at 29,500 tons worth $22.80 per ton above the 150-ft. level. A cyanide plant with a monthly capacity of 2100 tons has been installed, and monthly returns and profits should show a marked increase. Owing to the possibility of the lode being cut off by granite the price of the shares keeps at $16.80, although monthly dividends of 72c. per share are being paid.

Since being acquired by the Kalgoorlie & Boulder Firewood Co. the entire surface equipment of the Beria Consols (late Lancefield) has been overhauled. In addition, a new hoisting engine has been installed, as well as two suction-gas engines of 220 hp. each, driven by three 250-hp. (one as a standby) Commonwealth down-draught gas generators to burn 5-ft. firewood, to replace the steam engines and boilers to operate the treatment plant. Two vacuum-filters have also been added, and the all-sliming process has been adopted. The mine is now controlled by I. J. Dunstan, formerly metallurgist of the Associated company, and subsequently government inspector of state batteries. Archie Long, who was previously underground boss, has resigned a similar position on the Great Fingall mine to resume his old position. Mr. Long is confident that the estimate of ore reserves made by the previous management, of 250,000 tons with an assay value of $8.16 per ton is correct and will be confirmed by the mill. The staff of the Firewood company, which supplies the Sons of Gwalia mine with fuel, strongly advised the adoption of the Commonwealth wood-gas generator, after carefully watching the result for several weeks on the Sons of Gwalia mine. By adopting these generators consuming wood at $3.84 per ton, it is estimated that a monthly saving, over charcoal generators consuming charcoal at $14.16 per ton, of $170 will be effected on an output of 6000 tons.

The total mineral output of the state for 1913 was valued at $30,181,300 against $28,842,900, a decline of $1,338,400. There was an all round increase except in the case of tin, which showed a decrease of $14,000, owing to most of the known easily-worked deposits being worked out and no profitable lodes being yet discovered. The detailed output was as follows: gold, $27,908,500; copper, $712,600; lead, $295,000; tin, $360,700, and coal, $904,500. Gold output of the state in May

was $2,265,700, and dividends $69,600. Totals to date are $585,301,700 and $122,634,400 respectively.

The latest estimated ore reserves of the principal mines are as follows:

Name.	Tonnage.	Value per ton.
Great Boulder	688,900	$13.26
Ivanhoe	991,400	9.24
Perseverance	838,200	5.64
Golden Horse-Shoe	800,000	7.28
South Kalgurli	265,500	5.70
Kalgurli	260,000	9.44
Lake View & Star	420,000	6.66
Bullfinch	185,700	8.28
Sons of Gwalia	648,000	7.44
Mararoa	30,000	8.04
Edna May	29,500	22.80
Ingliston Consols	60,000	10.56
Fenian	70,000	14.40
Beria Consols	250,000	8.16
Menzies Consols	76,700	9.24

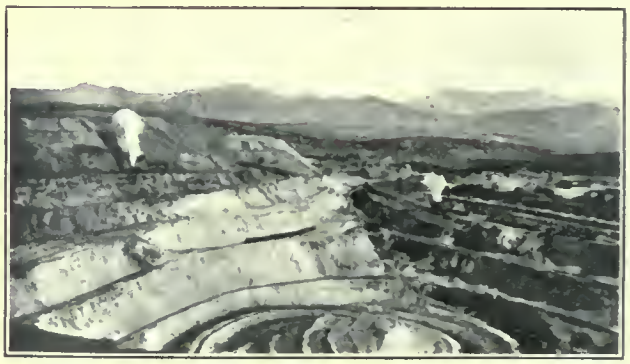
NEW YORK

SITUATION OF ZINC, SILVER, AND COPPER, AND PROBABLE CHANGES IN THE BUSINESS.—DIVIDEND PROPOSALS OF VARIOUS COMPANIES.

The peculiar effect of the war on metal prices is well illustrated in the case of zinc and silver. As has been widely remarked, the zone of fighting in Europe is just at places where most of the zinc production is made. As England draws most of her zinc supply from Europe, this has cut off the supply for the English trade. Orders have already been diverted to the United States, and as a result spelter has risen over 35% in price here, and is still going up. Curiously enough, though, the British companies in the important zinc-producing districts of Australia are in a bad way, and have already postponed the payment of dividends, while the Broken Hill Proprietary has canceled a dividend which it had already declared. The point of this is, of course, that shipments through the Suez canal are tied up, and the companies cannot get their zinc through to England, even though there would be a good market for it there. It would seem possible to divert the shipments from the Suez canal to the Panama canal route, but steamship lines are not well established through the latter yet, and besides, it is difficult for a company to totally change its method of doing business on short notice. In the meantime the Sulphide Corporation is negotiating with one of the large American zinc companies to handle its ore and, with an eye to the future, is investigating the possibilities of building its own works in Wales.

The situation of silver is also a peculiar one. The great demand for gold in the principal centres of Europe would naturally tend to draw gold out of India and China, and there ought to be a good market for silver in these countries. This theoretical consideration is, however, upset by the practical fact that the banking business of England is totally disarranged by the war, and as London has always been the silver market of the world, until this centre resumes dealing in silver there can scarcely be much of a market for it. The supply was very short in London last week, but the demand also seems to be equally short, for on the arrival of considerable shipments from America the price promptly went down again. It is decidedly doubtful whether there will be any considerable market for silver in London until the risk of shipping silver to the Far East becomes very much less. It would seem that the time is now ripe for San Francisco to make a bid for standing as a Far Eastern silver market. San Francisco is the nearest point of shipment for all the Nevada bullion, and if American banks were equipped to handle the business, that city ought to be able to control the silver shipments to China at least. Now that there is such tremendous excitement over the building up of the foreign business of the United States, it is possible that sensible laws will be passed which will permit Americans to have the banking and shipping facilities which are essential for foreign trade. The companies at Cobalt report that they intend to pay their dividends that accrue in the near future. None of the companies have been shipping bullion lately, but traffic between Canadian ports and England seems to be practically free of the possibility of German interference now, and it ought to be possible to resume shipments. It is reported that Holland made inquiries of the United States Government in regard to silver for coinage, and was referred to the American Smelting & Refining Co. Many of the foreign governments are coining silver, but the interference of the war with the manufacture of silver articles seems to be likely to more than overbalance any increased demand for coinage. On the face of it, indeed, it looks as though after this war is over Europe, as a whole, will be too poor to indulge in many luxuries. The diamond mines of South Africa have already foreseen the hard times coming, and are proceeding to close down their mines and send back the natives to their homes. Silver will also suffer in a similar way, and it can hardly be expected that the price of that metal is likely to rise very much in the next year or so.

The copper mining companies are operating steadily but on a reduced schedule. Some of them, which at first made only small reductions in output, have increased them so that practically all the plants in the country except the Lake Superior mines are now running on half time. The Michigan companies at first reported that they would keep their men working full time, but would make a 10% cut in wages. Later reports indicate that some of them will reduce their output. The Calumet & Hecla has stopped its construction work on its regrinding and leaching plant, and most of the other companies throughout the country that were in



EUREKA PIT OF NEVADA CONSOLIDATED, AT ELY, LOOKING NORTH.

process of increasing their output have stopped construction for the time being at least. The fall dividends for many of the companies are in doubt, and very likely will be passed, as it is very much better business for the companies to retain their profits to tide them over, in case operations are held up for a long time, than to pay them out now and perhaps need them later. On the basis of present production and prices, none of the copper companies, with possibly one or two exceptions, could pay the regular dividends without making a deficit. As these companies will need all of their money to carry unsold stocks of copper in case the market does not improve, it is obviously unwise to pay out dividends at this time. The domestic consumption of copper seems to hold up pretty well. Small shipments to Europe continue, and insurance rates have gone down to 1% in Italian vessels, and 2% in English vessels. During the week ended August 27, 1,917,816 lb. of copper was shipped to Europe, more than two-thirds going to Rotterdam.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

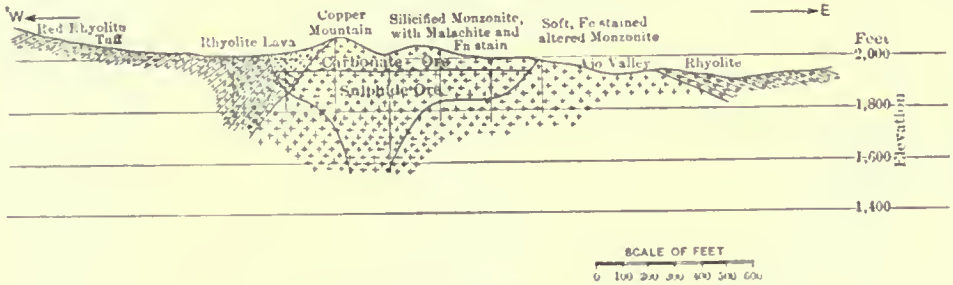
ARIZONA

Cochise County

Work has been resumed in stopes of the Southwest mine containing rich silver-lead ore, the Copper Queen company intending to operate as long as the silver market is regular.

Pima County

The Ajo copper mining district is described in the August *Bulletin* of the A. I. M. E. by Ira B. Joralemon of Warren, Arizona. Gila Bend is the nearest railroad point, 43 miles north, and Sonoita is 30 miles south on the Mexican border. Ajo is the only settlement of note between. The brilliantly stained iron and copper rocks of Copper mountain rise 150 ft. above the village of Ajo. The nearest abundant supply of water is the Gila river, 50 miles north. The district has been worked spasmodically since the '60s. Late in 1911 the Calumet & Arizona Mining Co. secured an option on the available shares of the New Cornelia Copper Co., and began prospecting with Longyear drills. This work, which totaled 23,097 ft., proved a great low-grade copper orebody, covering an area of about 55 acres, and reaching a maximum depth of over 600 ft. below the surface. Other options were taken by other firms, but they are doing little work. Unlike Bingham, Ely, Santa Rita, and other low-grade districts of the country, in which the copper is in the form of chalcocite, the disseminated ore in the Ajo area is a mineralization of the porphyry with chalcopyrite and bornite. Within the orebody, the monzonite is thoroughly shattered by a network of fractures. Reserves are estimated as 11,954,100 tons of 1.54% carbonate ore suitable for a leaching process and 28,303,600 tons of 1.5% sulphide ore suitable for concentration and flotation. About 7,776,800 tons of sulphide is not available for steam-shovels. To make the other available, 3,308,400 tons of 0.63% rock must be moved. The accompanying cut shows the structure of the orebody at Ajo.



VERTICAL SECTION THROUGH NEW CORNELIA OREBODY AT AJO.

CALIFORNIA

The oil production of this state in July was 9,185,176 bbl., or 296,296 bbl. per day, compared with 302,400 bbl. in June. Stocks at the beginning of August were 52,937,438 bbl., an increase of 792,431 bbl. over the end of June. There were 6261 producing wells. The most interesting developments in July were as follows: Midway-Sunset field, No. 10 well of the Consolidated Mutual Oil Co. completed at 3090 ft. depth, 1000 bbl. of 27 gravity oil per day; No. 3 well of the Honolulu Consolidated Oil Co., at 2594 ft., 1500 bbl. of 30 gravity; No. 4 well of Midlands Oilfields Co., at 3390 ft., 6000 bbl. of 25.1 gravity; No. 2 well of the Miocene Oil Co. is now yielding 8000 bbl. per day; and in the Coalinga field No. 9 well of the Turner Oil Co., at 3888 ft., 2400 bbl. of 30.5 gravity. No. 7 well of this Company is yielding 4000 bbl. per day. According to the *Standard Oil Bulletin* for August, the 10 oilfields of the state have a proved area of 78,770 acres, or 123.08 square miles. The yield to the end of 1913 was 658,069,946 bbl., or 8350 bbl. per acre.

It is expected that the U. S. Bureau of Mines rescue-car No. 5 will visit California mining districts from September 9 to October 31, the attendants giving training in mine rescue and first-aid work in some of the mining districts. The itinerary, which will probably be adhered to fairly closely, is as follows: September 9 to 19, Colfax; 20 to 27, Jackson; 28 to October 5, Angel's Camp; October 6 to 13, Melones; 13 to 20, Jamestown; and 22 to 31, Kennett. It is regretted that there is not sufficient time for the car to make a more extended trip through the state, but the Nevada itinerary was prolonged considerably beyond what was originally planned, and it is necessary for the car to return to the coal-mining districts of the Northwest before the winter season, so that an extension of the California itinerary is not possible at this time.

Amador County

Work on plans for the new mill and other equipment at the Argonaut are nearing completion.——At the South Eureka, 60 out of 80 stamps are crushing ore. The main shaft is now ready to handle the full tonnage.

Nevada County

After being shut down and reopened several times, the Union Hill mine has been bonded by E. C. Creller and others to B. Del Ray and W. H. Matson of San Francisco. A. D. Cox is to be in charge of work. The main shaft is down 600 ft. There is a complete mining and milling plant ready for work.——Some specimen ore was opened in the shaft of the Golden Center of Grass Valley mine last week. The shaft is down 600 ft. The new vertical shaft is being 'raised,' and is up 65 ft. out of a total of 214 ft. Twenty-five men are employed.

Placer County

A large deposit of good magnesite has been proved near Towle by J. D. Sullivan and J. H. Johnson. They were offered $150,000 for it, but now want $300,000.——Timber has arrived at Gold Hill for the new dredge for L. Gardella. Machinery for the boat will come from an old dredge at Oroville.

Shasta County

Owing to the scarcity and high price of ferro-manganese, the Noble Electric Steel Co. is preparing to 'blow in' one or two electric furnaces, which will each make five tons of this product per day. A large deposit of manganese lies four miles from the smelter.——Mining men of the Copper City district are to ask for a road to be constructed to connect with the state highway at Redding.

Sierra County

A 300-ft. vertical shaft is to be sunk by W. F. Copeland

and associates at the Bald Mountain gravel mine near Forest. Some machinery has been ordered, but more will be needed later on.——According to the superintendent of the Tightner, Abraham Hall, the mine and mill are being worked at full capacity. A contract has been let for 60,000 board feet of round timber for underground.

TRINITY COUNTY

There is considerable activity about quartz mines in the Helena district. The Enterprise 10-stamp mill is recovering about $20 per ton. Others being developed are the Golden Chest, Yellow Rose, and Oversight.

COLORADO

LAKE COUNTY (LEADVILLE)

Orders are expected at any time to restart the new zinc smelter, according to the manager, Mr. Augustine.——The Dinero Mining Co. is resuming work.——Lessees at the New Monarch property continue to produce a good tonnage of silver-gold ores.——Sub-lessees at the Castle View are shipping a large amount of iron ore containing silver.——The Virginius Tunnel claims are closed until the silver market is regular.——Work in the Half Moon and Lackawanna districts proceeds as usual.——From the Mt. Champion mine a good deal of high-grade gold ore is being extracted.——Officials of the Down Town pumping scheme are not sure when the pumps will arrive from Switzerland, on account of the war.

SAN JUAN COUNTY

At the Hamlet Mining & Milling Co.'s property at Middleton, near Silverton, the mill is to be overhauled and its capacity increased to 100 tons per day. A good tonnage of copper-lead-zinc-silver ore has been developed. Etienne A. Ritter, of Colorado Springs, is manager.——The new Wilfley-Mears 600-ton mill is at work treating old tailing from the Silver Lake mine. There is about 500,000 tons of material to be treated. C. J. Estabrook is manager for A. R. Wilfley, Otto Mears, and others.——A flotation process is being installed at the Gold King mill, according to Louis O. Bastian.

SUMMIT COUNTY

The metal market has not affected the Breckenridge district, and the mines and dredges are producing their regular amount of gold and zinc.

TELLER COUNTY (CRIPPLE CREEK)

Soft ground has hindered good progress in extending the Roosevelt drainage tunnel. The flow of water is now nearly 10,000 gal. per minute, against 7590 gal. at the beginning of the month.——According to the president of the company, John T. Milliken, the Golden Cycle mill's output of metal, about $500,000 per month, will be held in Colorado to assist banks of the state.——The Elkton company has paid a dividend of 2c. per share, amounting to $50,000. The total to date is $3,429,460. Work in the mine is now proceeding on No. 14 level.——Water being under control in the Ajax property, lessees have resumed work on No. 12 level of the main shaft, and are cross-cutting in ground under the rich granite shoot.——A lease has been secured on the C. O. D. mine by Melville B. Rapp, of Cripple Creek, who will start active work on the property, which was idle for some time. He will sub-lease certain areas. The output to date is over $750,000.

IDAHO

BLAINE COUNTY

Twelve miles from Hailey is the Nau Aug mine, leased to Salt Lake people. A new shoot of ore, opened 50 ft. below the 700-ft. adit is 6 ft. wide and assays about 76% lead and 100 oz. silver per ton. A little zinc ore is on the hanging wall. A 30-ton mill has been designed by Kirk & Leavell, Salt Lake City.

SHOSHONE COUNTY

The eleventh annual miners' picnic was held at Kellogg on August 21 and 22, several thousand attending. There were aeroplane flights, motorcycle races, log-rolling and sawing contests, dancing, boxing, auto parade, gun-club shoots, baby shows, and speeches. Among the speakers was Stanly A. Easton, of the Bunker Hill & Sullivan company, who thought that the war would be a boon rather than an injury to the Coeur d'Alene mining industry, if the present trend of prices continues. This Company on September 4 paid dividend No. 204, amounting to $81,750, with a total to date of $15,465,000.

It is stated that the Interstate-Callahan company will probably add to its milling capacity by erecting a zinc concentrator at the junction of the north and south forks of the Coeur d'Alene river, which is an ideal site. Large reserves of zinc ore are open in the mine.

MISSOURI

JASPER COUNTY

On account of the higher prices for spelter, leases which have long been idle in the Missouri-Kansas-Oklahoma district are being re-worked. Other mines have added one or two shifts per day to the working force. During the week ended August 22, sales of zinc ore were numerous, and prices on basis of 60% metal rose to $43, $46, $47, $48, $49, and $49.50 per ton. Calamine was strong at $22 to $23 basis of 40% metal. Lead ore was unchanged at $46, basis of 80% metal. The district's output was 4013 tons of blende, 489 tons of calamine, and 770 tons of lead ores. Water in the Picher land, northwest of Joplin, has been lowered to 130 ft., with another 20 ft. to go. The north pumping plant on the Granby land has the water below the old workings. A number of lessees are working on these lands.

MONTANA

SILVERBOW COUNTY

Labor troubles are again causing uneasiness at Butte, the outbreak being among the men themselves. Last week a fire at the Anaconda company's Mountain View mine destroyed property worth $100,000. On August 30 the employment office at the Parrot mine was dynamited. The governor, Samuel V. Stewart, has ordered the mobilizing of the state militia of about 600 men at Helena, and has sent them to Butte. The miners union numbers about 8200 men, who are said to be armed and in a bad mood. On account of a broken crank shaft of the Moonlight hoisting engine, this mine is shut down, 320 men being out of work.

NEVADA

Great interest is being taken in the mine-rescue and first-aid contests which are to be held on Labor Day, September 7, at the University of Nevada, Reno. J. G. Scrugham, of the engineering department, is organizing the meeting. There will be 17 teams from all parts of the state. The State Electrical Association will meet and discuss papers.

CHURCHILL COUNTY

The Nevada Hills mine produced 5610 tons of ore in July averaging $7.29 per ton. Loss in residue was 72.7c. per ton. Net profit was $6574. Resources of the Company amount to $238,614, including cash, $8376; silver on hand at 52c. per ounce (28,290 oz.), $14,716; concentrate in transit, $6593; and supplies in store, $45,519. There are no liabilities. The Company has enough supplies to last for several months.

ESMERALDA COUNTY

So far for August the Florence mine shipped about 450 tons of ore to the Western ore sampler at Millers. The mine is opening well——At 350 ft. in the Sandstorm-Kendall, 18 in. of $32 ore has been opened for 10 ft.——Encouraging results

are being met with in the Oro mine.——An air-compressor and machines have been ordered for the Yellow Tiger.——Final figures of the Goldfield Consolidated for July show that 24,548 tons yielded $151,076 profit. Development of 2348 ft. cost $7.85 per foot. Total costs were $6.80 per ton, including filter royalty of 5c. per ton.

Lincoln County

According to H. W. Rand, general manager of the Gold Chief Mining Co., operating near Caliente, the mill is treating 165 tons of $5 gold ore per day. The profit is $5000 per month. A main incline shaft has been sunk 450 ft. At 200 ft. a dike altered the formation, but the lode was found again and is now 10 to 25 ft. wide. Reduction and treatment involve using a crusher, trommels, belt-conveyor, rolls, and six leaching vats, the ore being leached by cyanide for 60 hours. An average of 87% is recovered. H. Dietz is in charge of the mine, and H. Franklin is mill superintendent.

Lyon County

The Mason Valley smelter received 2659 tons of ore during the week ended August 26. The mine is keeping up its shipments. The 20-ton experimental leaching plant at the smelter is ready for work.——A number of men have been laid off at the Nevada-Douglas. Construction of the leaching plant is under way.——From the Empire-Nevada 500 tons of ore is being sent to the smelter's test leaching plant.

Mineral County

(Special Correspondence.)—The Luning Gold Mines Co. expects to start work in the near future.——The Shipper Copper Mining Co. has recently arranged with Carl R. Dwight for taking over the Alamedis property at Lime Point, and funds have been raised for the extensive development of both properties.——The Luning-Idaho Mining Co. recently made an important discovery in driving an adit which has crosscut a body of high-grade copper ore said to contain 10% copper and about 2 oz. silver. This is at considerable depth in a porphyritic formation, and is considered one of the most important discoveries in that district.——Joseph L. Geroux, operating a property near the above mine, exposed a new body of high-grade copper ore on the 700-ft. level.

Luning, August 27.

After many years the old gold camp of Douglas, seven miles west of Mina, has resumed bullion shipments, the Davenport-Independent Mining & Leasing Co. crushing and cyaniding 100 tons of ore for $2500. Gus Priess is manager.

Nye County

The first 45-ton shipment of ore from the White Caps mine at Manhattan has been sent to the Western Ore Purchasing Co. Some of the ore mined averages $50 per ton. The oxidized ore is to be milled locally.——The Associated mill is treating Manhattan Consolidated ore. A shortage of water has hindered regular work.——The Commercial Mines & Milling Co.'s claims are being sampled for Eastern people. About 80 samples are assayed daily at the War Eagle mill assay office. Two Cyclone drills, made in Orrville, Ohio, are to be used in prospecting. They are straight churn-drills, a bailer being used, after the hole is sunk, to raise the hole contents to the surface. The drills are mounted on tractors, driven by the same power as the drills, an 18-hp. gasoline engine. The outfit weighs 6½ tons complete. These machines are especially good for holes down to 300 ft., but are guaranteed for 800 to 1000 ft. George White is in charge of this drilling work.

Ore production of the Tonopah district in July was 50,011 tons worth $875,630. For the past week it was 10,499 tons, valued at $198,335. A new shoot of rich ore has been cut at 900 ft. in the Belmont.——The new shoot at 440 ft. in the Silver Top ground of the Tonopah Mining Co. shows 5 to 6 ft. of good ore in the raise.——A good shoot is being opened at 700 ft. in the Jim Butler.——The Extension bullion output is estimated at $110,000 gross for August.——For silver in its concentrate the Montana received 56.625c. per ounce.——Final clean-up of the MacNamara was worth $14,650.

Storey County

In a report on the plan of exploration now in progress in the Mexican and Union Consolidated mines on the Comstock, Whitman Symmes, the superintendent, makes the following remarks: "The greatest possibilities for discovery of ore in Union ground appear to lie below the 2500-ft. level. The Union-Sierra Nevada joint winze was pumped out, and a cross-cut started at 2650 ft., 100 ft. below the general water-level of the north-end mines. The work was out 20 ft. on August 18. The next two levels of the Mexican and Union will be the 2650 and 2800-ft., and the old 2700 and 2900-ft. levels can be used as reservoirs in case of temporary stoppage of the United Comstock Pumping Association's pumps. Previous inconvenience will not recur. At the north end of the Comstock lode, ore in the hanging wall has been found near a dacite dike, which acts as a convenient indicator. At 2500 ft. this dike, coming northeast from the Mexican orebody crosses the Union west cross-cut at a point 565 ft. from the Union winze. At 2650 ft. it should be met with 100 ft. nearer. So far ore has been found either against the dike or a moderate distance from it. In the cross-cut a second dike is exposed 235 ft. from the joint winze, it being thin and parallel to the other dike, and also dipping toward the winze. The two dikes are 330 ft. apart. The east country diabase contains many lenses of diorite, prominent at 2500 ft. If a new lens of this rock is found in the new Union 2650 ft. west cross-cut, near the east dike, there should be some ore there. The Mexican company is to start a new level at 2650 ft. in the inclined winze, and a north drift driven along the main shearage to the Union line. The Union company can then continue exploration into Union ground, which at 2650 ft. appears promising. The Mexican company can also continue prospecting deemed worth while. At the 2500-ft. level of the Mexican, in the joint cross-cut there is a large area of mineralized formation containing quartz stringers over 90 ft. wide. While low-grade, it is probable that at 2650 ft. it will be of better grade. Generally the work to be done is promising.

UNION SHAFT THROUGH WHICH THE MEXICAN AND UNION MINES ARE BEING EXPLORED.

UTAH

Juab County

The Grand Central Mining Co. has declared its third dividend of 5c. per share, or $25,000, this year. Total to date is $1,602,750. The mine is in good condition.——The Gold Chain will resume work shortly.——It is proposed to concentrate the 18 to 20% zinc ore of the May Day, of which there is a good tonnage. Ore assaying 30 to 40% lead and 22 to 24 oz. silver was shipped last week.——Water amounting to 75 gal. per minute has been encountered in the Dragon Consolidated. Ore being mined is more than paying expenses.——Sinking to 1700 ft. has been started at the Eagle & Blue Bell.——Rich

gold ore is reported to have been found by the Centennial Eureka company.——Ore shipments from the Tintic district last week, from 13 mines, totaled 91 cars.

Piute County

Owing to the potash supply from Germany being cut off, attention is being given the alunite deposits at Marysvale.

Salt Lake County

There will be no decrease in stripping work at the Utah Copper mine; the management planning to remove as much ground as last year, when the total was 4,835,479 cubic yards.

Summit County

A Christensen roasting furnace, constructed at Provo for the Park City Mills Co., is now being installed at the plant. Ore from the American Flag mine will be the first to be treated in the mill. Results are awaited with interest.

Stevens County

Forest fires interfered with work at the United Copper mine last week. The Company has a few men in the mine and one shift at the concentrator.——No. 3 vein is being opened at the Copper King.——At the Chewelah Consolidated a contract has been let to cross-cut on the 150-ft. level to prove the orebody.

CANADA

Alberta

(Special Correspondence.)—The war in Europe has had at least one beneficial effect on Alberta, it having stopped the oil boom, and given the oil (?) men an excuse for the drop in price of stocks, which were well on the downward slide long before war was heard of in Alberta. Many shares have no market value at the present time, and those which were thought to be good are well within the reach of the newsboys, and few are being sold. Three months ago every office was an oil company's office, but now 80% of them are closed. One interesting feature found is that the Judith River beds, as well as the Bear Paw shales of Edmonton and Paskapoo in eastern Alberta and western Saskatchewan, show the marked effect of the great thrust from the west. This region is 250 to 300 miles east of the Rocky Mountains thrust fault, but notwithstanding this distance the beds are intensely faulted, overturned, and in places faulted by the same forces which formed the mountain range. There have been found small areas where the beds lie almost horizontal, but most of the outcrops of any extent show either folds or faults. There have been no new oil discoveries, only a little gas in some wells being drilled. All unnecessary development in the province by railroad and government has been suspended on account of the war. Crops around Edmonton are good, but light in the south part of Alberta.

Edmonton, August 18.

Ontario

The silver situation at Cobalt is much better, and full operations are being resumed. All the Nipissing mines and works are in complete operation. The banks are to supply sufficient cash to enable the mines to produce bullion at the properties. Ore and concentrate shipped outside are not in so good a position, but some are receiving their bullion from the smelters instead of cash. A shipment of 55,000 oz. has been sent to London by the Crown Reserve company. This Company is paying a 2% dividend, or $35,376, on September 13. The McKinley-Darragh distribution on October 1 will amount to $134,862. The Porcupine Crown pays 3%, or $60,000, on October 1.——The Buffalo mill treated 6985 tons of 13.85-oz. ore in July, yielding a total of 97,136 oz. Silver sold up to August 20 was 342,417 oz. That on hand in London when war was declared netted 59c. per oz. The concentrating mill is now shut down, but some mercury is being recovered from residue at the high-grade mill. Underground development work is under way.

PERSONAL

Franklin Guiterman is in Colorado.

J. Allen Veatch is examining mines in Shasta county, California.

J. P. Keene has returned to Woodland, California, from Montana.

Daniel and S. R. Guggenheim have arrived in New York from Liverpool.

E. H. Benjamin has been placed in charge of the Mariposa Grant mining matters.

Anton and Karl Eilers and Isaac Guggenheim have reached London from Rotterdam.

J. W. Hutchinson, of the Goldfield Consolidated, is at the Adler Sanatorium, San Francisco.

George Watkin Evans, mining engineer of Seattle, is examining coal properties in Montana.

C. T. Griswold has returned from examining several gold prospects in the Sudbury mining district.

Leon J. Pepperberg is in Los Angeles from Calgary, Alberta, and will be in San Francisco in a week or so.

Ferdinand McCann has left Manila for the Argentine Republic, traveling by way of the Mediterranean.

William H. Grant has gone to Mogollon, New Mexico, to make a geological survey for New York clients.

C. B. Lakenan was operated on successfully on August 25, and a complete recovery is expected.

P. R. Bradley has been made general superintendent of the Treadwell group of mines in place of Robert Kinzie, resigned.

L. G. Huntley, formerly of the Associated Geological Engineers, has left for Colombia, S. A., for examination of oil properties.

A. L. Queneau has gone to join his regiment in France and is doubtless now at the front. He left his family at Jemeppe sur Meuse, and they have probably taken refuge in Antwerp.

F. Yamada, a mining engineer of Tokio, Japan, was in the Coeur d'Alene district recently. Mr. Yamada has spent the past year in the mining districts of the United States and Canada studying various mining methods.

Francis Church Lincoln, until recently resident engineer for the Bolivian Development & Exploration Co., at La Paz, has left the employ of that Company to become head of the Mackay School of Mines, at the University of Nevada, Reno.

Victor C. Lednicky, who has been engaged in mining in Honduras for the past three years, has been appointed to the staff of the division of mines, Bureau of Science, Manila, and will leave San Francisco for the Philippines early in October.

Wallace E. Pratt has been promoted to the position of chief of the division of mines, Bureau of Science, Manila, to succeed Warren D. Smith, who resigned to accept appointment as head of the department of geology, University of Oregon, at Eugene.

A. M. Walsh has resigned as superintendent for the United Comstock Pumping Association and will be succeeded by Thomas F. McCormick, superintendent for the Consolidated Virginia and Ophir companies. Charles Liddell has resigned as surveyor for the Association.

The American Chemical Society has indefinitely postponed its meeting called for Montreal, Canada, from September 14 to 18, on account of the war in Europe. As far as can be seen, the next meeting of the Society will be held in New Orleans, on April 1 to 3, 1915. There are now over 7100 members.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, September 3.

Antimony	15 —15¾
Electrolytic copper	14 —14¼
Pig lead	4.15— 5.10
Quicksilver (flask)	$75— $85
Tin	41 —42½
Spelter	7¾
Zinc dust, 100-kg. zinc-lined cases	20

The above quotations represent small transactions only, and would not apply for any considerable business. Zinc dust in New York is reported to be much higher, with small stocks.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 3.—The copper market is unchanged, lead is quiet at 3.90c., and spelter is weaker at 5.75c. The Calumet & Hecla has passed its dividend, and it is predicted that the Amalgamated and Anaconda will either do likewise or cut the distribution. Braden mine produced 1,840,000 lb. of copper during the first half of August. The metal now goes to New York by way of the Panama canal. The U. S. Steel Corporation is operating at 77% capacity, against 70% the preceding week. Crude drugs, chemicals, and dyes are short, and Germany will try to send them by way of Rotterdam in Dutch steamers. Platinum is easier, from $18 to $50 per ounce. Depreciation of 387 securities on the London Stock Exchange was $910,000,000 during the last 10 days of July.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 27	No quotes	July 15	55.60
" 28	" "	" 22	54.14
" 29	" "	" 29	53.12
" 30 Sunday		Aug. 5	No quotes
" 31	" "	" 12	" "
Sept. 1	" "	" 19	" "
" 2	" "	" 26	" "

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	....
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

In the absence of any regular market, no average price can be given for August. The New York Assay office has been paying 52c. per ounce for silver contained in gold bullion. Recent quotations in New York were around 54c., while in London the past week has recorded 23.82d., 24.25d., 24d., and 22d. per ounce for bar silver. Through the curtailment of copper output, silver production will be reduced by from 650,000 to 750,000 oz. per month, which should make a better market for direct silver producers. Business in the metal in London has been confined to liquidating outstanding contracts, while purchases for coinage have been negligible. Supplies from the United States and the absence of competition have combined to reduce the price.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per pound more. Prices are in cents per pound.

Date.		Average week ending

May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

No average is possible for August. The "American Metal Market" states that there has been small buying, and quotes the following: prime Lake, 12.50 to 12.75c.; electrolytic, 12.35 to 12.45c.; and casting, 12.25 to 12.35c. Exports in August totaled 19,676 tons, against 34,722 tons in the same period of 1913. The Metal Exchange in London has reopened to deal on settlement prices only, namely £56 10s. per ton, or 12.10c. per pound, to help liquidate existing contracts.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July 30	37.50	Aug. 20	No quotes
" 13	85.00	" 27	80.00
		Sept. 3	75.00-85.00

Monthly averages.

	1913.	1914		1913	1914
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	....
Mch.	40.20	39.00	Sept.	39.70	....
Apr	41.00	38.90	Oct.	39.37	....
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

This metal sold from $75 to $90 per flask, wholesale, in New York during the last week in August. On account of the erratic market it is not possible to give an average for the past month.

TIN

Monthly averages.

	1913.	1914		1913.	1914
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept	42.45	....
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.20	Nov	39.77	....
June	45.10	30.72	Dec	37.57	....

The high average for August was entirely due to war conditions, and prices ranged from 65 to 39.50c., at which latter they now stand. The market is quiet, and a shipment is expected. The Dutch government will hold the postponed Banca sale of 2500 tons on September 5, for which it has set the limit at 37.50c. The London Metal Exchange is doing business at settlement prices, namely, £133 per ton, or 28.50c. per pound, to help liquidate existing contracts.

New York Metal Review

The breaking out of war in Europe has changed the complexion of nearly all of the metal markets, and developments have been rapid and some price changes radical during the month. Lead has been fairly steady, the only one to hold thus. Tin has been exceedingly erratic; now wild, now quiet, now up and down. Spelter has also advanced decidedly and steadily because of war conditions, while antimony has gone up nearly four times its former price, due to the same causes. Copper has suffered a setback, due to exports being largely curtailed requiring further reduction by the producers. Conservatism has ruled largely in all branches, but more steadiness was apparent toward the end of the month, as well as a better tone.

COPPER

The predominating factor in the copper market has been the extent of curtailment of copper production as a result of the war. As soon as this broke out, it was recognized that exports might entirely cease, or at least be greatly lessened. Since these constitute nearly 60% of our monthly production, the effect on stocks in this country can readily be appreciated. Early in the month, therefore, the market came to a standstill, and quotations were nominal. The situation was further complicated by the announcement that the Copper Producers' Association would issue no more monthly statements for the present. The nominal quotation for Lake was 12.87½c. early in August, and 12.50c. for electrolytic. Since then the price has declined, as based on small sales, to 12.75c. and 12.25c., respectively. Very little business was done during a greater part of the month. Conservatism prevailed and consumers bought only what was necsesary, awaiting developments as to curtailment of production, stocks available, prices, exports, etc. During the last week in the month some demand appeared and prices advanced slightly to 12.50c. for electrolytic. Not much business developed in Lake, and none was to be had at less than 13c. As the month progressed, England gained firmer control of the sea and exports increased on demand from that country. Up to August 25, exports had amounted to 15,404 gross tons, mostly to England, compared with 28,175 tons for the same period in July. This, under the circumstances, is regarded as excellent. These exports, together with the development of some business during the past week, contributed to a better tone. The Waterbury average for July was 14.12½c. per pound.

LEAD

The price in New York has varied but slightly during August, being 3.90c. early in the month, dropping to 3.85c. near the middle, and then advancing to 3.87½c. toward the close. This latter price is lower than that of the large interest. This is really the only metal that the war had not affected decidedly. Whether there will be any marked influence from that quarter later is debatable. Some look for a foreign demand and also a curtailment in domestic production because of the situation in silver, but this now appears decidedly better. During the last week in the month sales were made for export and shipments went forward. The Bureau of Foreign and Domestic Commerce, Department of Commerce, reports the total amount of lead remaining in warehouses June 30, 1914, at 14,473,010 pounds.

SPELTER

Outside of tin this metal has been more decidedly influenced by war conditions than any other. Previous to August the market had been dull and prices ranged close to 5c., New York, with a slight advance the last week in July. By the end of the second week in August the New York price had gone to 5.75c.; this movement continued until the metal was quoted in this market at 6 to 6.15c., New York, during the last week in August, with the prospect of the price going higher or quotations being possibly withdrawn. The cause for this market condition is attributed directly to heavy inquiry from England and Canada, brought about by the usual Continental supplies being cut off. Producers have taken advantage of this unusual situation and hid up the market. Strange to say, the domestic demand has been quiet. Figures compiled by the U. S. Geological Survey on the zinc situation were published in full in the *Press* of August 22 and 29.

TIN

War conditions have caused considerable fluctuation in this metal, and during the greater part of the month it has been decidedly erratic, with prices in most cases nominal. Early in the month, after England declared war on Germany, fear seized consumers and there was a rush to buy. It was expected that the supply from England might be entirely cut off. A report was issued that England had placed an embargo on tin. Prices advanced on small sales to 65 to 68c. by the middle of the second week. The London and New York metal exchanges closed and quotations were impossible. By the middle of the month the tension was relieved, and prices began falling until 39c. was reached about August 17. This was followed by a further rise of 10c., and again a fall to 39 to 40c. during the last week. The embargo report was found to be unfounded, as shipments began to appear, due to England's command of the sea, increasing in volume beyond anything thought possible, until arrivals up to August 25 were reported to be 2330 tons, with 1620 tons afloat. These revelations caused a decidedly easier tone until the market during the last week became dull, with very few transactions and spot tin a drug on the market. Juiy deliveries totaled 3900 tons, and the total for the seven months of 1914 showed a decrease of 600 tons, as compared with the same time last year. The total visible supply July 31, 1914, was 14,167 tons, as against 12,063 tons July 31, 1913. The total tin afloat at the close of July was 5519 tons, as against 7251 tons in June 1914, and 6731 tons in July 1913. Government statistics show that the exports of tin to Pacific ports in June (by districts) were as follows: Oregon, 6727 lb; San Francisco, 227,312 lb.; and Washington, 124,118 pounds.

ANTIMONY

Being dependent on Europe for this metal, the war has caused a decided advance in prices. Consumers are regarded as being pretty well supplied, however. Imports have largely been stopped and quotations are nominal at 18 to 20c. for Cookson's, 16 to 18c. for Hallett's, and 14 to 16c. for other grades. Should Japan, because of her entry into war, place an embargo on the metal, a famine would ensue.

ALUMINUM

The aluminum market does not display any activity. It is reported that holders of spot metal do not find it easy to make sales. The quotation for domestic metal, 98 to 99% pure, on August 26 was 20 to 21c. The average price for July was 17.59c., compared with 23.34c. in July 1913. According to official figures the imports for June were 489 gross tons, making a total of 3435 tons for the first six months, as compared with 6629 tons to July 1, 1913.

GRAPHITE imports into the United States have been interrupted by the war. The output in 1913 was 4775 short tons, worth $293,756. Imports were 28,879 tons, valued at $2,109,791. The U. S. Geological Survey states that cutting off the foreign supply would affect only the crucible industry. This absorbs about 55% of the graphite consumption, and comes mostly from Ceylon, also a little from Madagascar. There is ample graphite in the country for stove polish, foundry facings, paints, etc. Large deposits of amorphous graphite occur in northern Mexico, Canada, New York, New Jersey, Pennsylvania, North Carolina, Alabama, Texas, and other states.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-40s	8¾	6s-14 oz-20s	9½

Antimony ore, 50%, per ton	*$27.50	$30.00
Arsenic, white, refined, per lb	0.05	0 06
Arsenic, red, refined, per lb	0.12	0.15
Asbestos, chrysotile	100.00	350.00
Asbestos, amphibole	5.00	10.00
Asphaltum, refined, per ton	11.50	20.00
Barium chloride, commercial, per ton	50.00	60.00
Barium sulphate (barytes), prepared, per ton	20.00	30.00
Bismuth ore, 15%, per ton	*250.00	upward
China clay, English, levigated, per ton	15.00	20.00
Chrome ore, according to quality, per ton	10.00	12.50
Cobalt metal, refined, f. o. b. London, per lb.	2.50	....
Coke, foundry, per 2240 lb	12.00	15.00
Diamonds (according to size and quality):		
Borts, per carat	2.00	15.00
Carbons, per carat	55.00	80 00
Feldspar, per ton	5.00	25.00
Firebrick:		
Silica, per M	50.00	55.00
Snowball, per M	40.00	45.00
Flint pebbles for tube-mills, Danish, per 2240 lb.	26.00	30 00
Fluorspar, per ton	10.00	15 00
Fullers earth, according to quality, per ton	20.00	30 00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb	0.01½	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Iridium	55.00	....
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	20.00	25.00
Manganese ore, oxide, crude, per ton	10.00	15.00
Manganese, prepared, according to quality, per ton	30.00	70.00
Mica, according to size and quality, per lb	0.05	1.00
Molybdenite, 95% MoS_2, per ton	750.00	1000.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb	1.60	2.00
Osmiridium, per oz	25.00	....
Platinum, native, crude, per oz	30.00	45.00
Silex lining for tube-mills, per 2240 lb	35.00	45.00
Sulphur, crude, per ton	25.00	30.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	425.00	450.00
Tungsten ore, 65%	400.00	425.00
Uranium ore, 10% min	25.00 per unit	
Vanadium ore, 15% V_2O_5, per ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.

*Extra charge for packing nitric acid for shipment to conform to regulations.

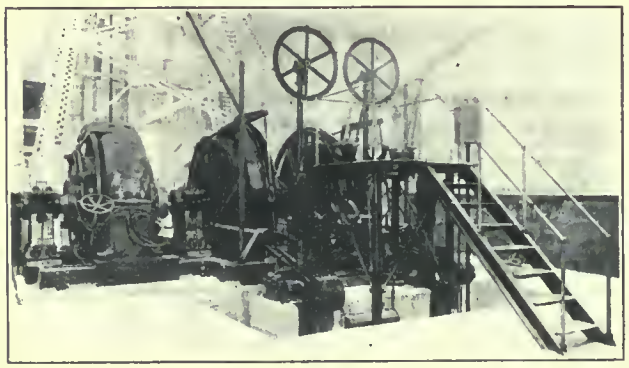
Bullion received at the San Francisco Mint in August was 222,082 oz. gold and 812,875 oz. silver, of a total value of $5,219,616. Coinage executed amounted to $4,358,950. Coin, bullion, etc., on hand at the end of the month was worth $249,880,032.79.

New Machines and Devices

First Motion Electric Hoist

The accompanying illustration shows a modern electric hoisting plant recently installed by the Silver King Coalition Mines Co. at its mines near Park City, Utah. This hoist is erected in a large concrete chamber at the inner end of a 2-mile tunnel from which point a vertical shaft connects with the lower workings of the mine which will eventually have a depth of 1200 or 1300 feet. In order to set the hoist as closely as possible to the collar of the shaft and avoid expensive rock excavation, flat ropes were decided upon as best adapted to the requirements. The hoist consists of a double-reel machine directly connected with a 200 hp., 575-volt direct current motor, which together with the controlling mechanism, was furnished by the General Electric Company.

Each reel has a capacity for 1300 ft. of 4 ft. by ⅜-in. rope,



DOUBLE REEL FIRST MOTION W-S-M ELECTRIC HOIST AT SILVER KING COALITION.

and the load on each reel consists of a double-deck cage with two cars of ore, and, including the rope, approximates 13,000 lb. While the hoisting will ordinarily be done in balance, the hoist is so arranged that either reel can be operated independently of the other, as required. The load is hoisted at an average rope speed of 1200 ft. per minute. The reels are loose on the main shaft, having removable bronze bushings, and are fitted with powerful band friction clutches and heavy post brakes, the clutches being air operated and the brakes of the gravity type, that is applied by weights and relieved by air cylinders.

An automatic slow-down device is connected with each reel so that when the cage reaches a certain distance from the collar of the shaft the hoist is slowed down by the controller lever being gradually thrown to the central position. In addition to this, should the operator fail to stop the cage at the collar of the shaft, the brakes are automatically applied by the safety stop system operated by two hatchway limit switches, one located in each shaft compartment.

All operating levers are conveniently grouped on an elevated operating platform from which the operator has a clear view of the cage as it reaches the landing point at the collar of the shaft. The hoist is placed on a substantial concrete foundation in a concrete arched room, and a heavy steel headframe is erected over the shaft, which may be seen in the accompanying illustration. The plant is most modern, and efficient. The hoist employed was manufactured by the Wellman-Seaver-Morgan Company of Cleveland, Ohio.

Commercial Paragraphs

The Malm-Wolf Company has moved its offices to First National Bank Bdg., Denver, Colorado.

Denver Quartz Mill and Crusher Company is distributing an illustrated folder devoted to the Denver quartz mill and the Denver ore crusher.

A carload of Cushman high-power gasoline engines is due in Sacramento. These little 4 hp. engines are finding many uses and proving much in demand.

General Filtration Co. Inc., Rochester, N. Y. is distributing a brochure entitled 'Filtros' which is devoted to the new porous mineral medium manufactured by this company.

Duriron Castings Co., New York. Bulletin devoted to 'Duriron' as used for plug cocks, check valves, pumps, and all kinds of castings. Duriron is claimed to be an acid, alkali, and rust-proof iron alloy.

Western Electric Co., New York, has for distribution a new publication entitled 'Magneto Telephones and Supplies.' The catalog lists the apparatus and equipment for small lines having up to 200 telephones. 'Telephone Cords' is the title of another publication of this Company.

Chicago Pneumatic Tool Co., Fisher building, Chicago, Illinois, has issued Bulletin No. 153, devoted to the 'Chicago Sinker,' a hammer-drill for which is claimed distinguishing features. The bulletin contains many illustrations showing the construction and operation of this type of drill.

Ingersoll-Rand Co., New York City, has recently issued two new catalogs, No. 3024 and 3030, on Ingersoll-Rogler air-compressors. Catalog 3024 contains a description of the Ingersoll-Rogler valve, and catalog No. 3030 describes the class ER-1 type of compressor. Both catalogs are profusely illustrated, showing the details of the machine.

Electric Weighing Co., New York, presents a bulletin devoted to the Messiter conveyor scales. The bulletin describes in detail the action of the Company's conveyor scales for belt and pan conveyors and the duplex scales for pivoted bucket carriers. The Company also manufactures automatic tonnage regulators and mixing systems.

Sutton, Steele & Steele, Denver, Colorado, is offering a screenless sizer for which many claims are made as to its adaptability to sizing any free, dry, pulverous mass containing 4 mesh or even larger down to 200 mesh, or finer in the same operation. The sizer is installed in the Denver mill of this Company, where it is being demonstrated.

Busch-Sulzer Bros.-Diesel Engine Co., St. Louis, Missouri, has for distribution Bulletin 109, containing a discussion of power economy with the Diesel engine. The bulletin contains charts illustrative of efficiency and fuel consumption, together with other interesting details regarding power-plant economy. A booklet entitled 'Evidence' contains extracts from letters regarding the performance of the Diesel engine.

H. W. Johns-Manville Co. is introducing a machine into this country which makes it practicable for anyone to manufacture ice on either a small or large scale. The machine is a French invention and was designed primarily for ice making for factories, stores, residences, mines, smelters, and the like. The machine is unique in many ways, it occupies comparatively small space, is entirely self contained, and requires no recharging.

MUCH enterprise has been shown by the United States Geological Survey in the prompt preparation and publication of *Bulletin* 599, which deals with 'Our Mineral Reserves—How to Make America Industrially Independent.' The war has disturbed many trades and cut off foreign supplies of various sorts, including many products of the mines. It has also opened neutral markets to the United States under most favorable conditions. The bulletin just issued is authoritative as well as timely and should be widely read and studied.

FIRM is the public belief that a long life and a green old age is a lapsed characteristic of our pioneer ancestors; that in the strain, rush, and hurry of modern life men are snuffed out like candles in middle age. And yet among the fifteen persons whose deaths were noted in a New York daily paper of September 2, we note such robust figures as Austin Cronin, aged 106; Almond F. Cooper, 97; Squire Fox, 86; J. S. Sands, 74; E. S. Bradford, 71; E. W. Bradley, 67; and J. S. Brockington, 66. One-third of those whose deaths are noted had passed the Biblical three score and ten. Two thousand years ago the Greeks pictured their present day as one of degeneracy; apparently human nature has not much changed since then.

"SHOULD the American people take advantage of the golden opportunity afforded them by the outbreak of the war, it will mean not diminished, but increased prosperity for the United States." This sentiment from the *Statist* of London has been expressed and repeated by many of our economists and while present trade conditions are disturbed, this feeling of optimism is to be felt in all of the industries. Even though the important German merchant marine has practically suspended operations, many of the English and French boats acting under the protection of the fleets of the allied nations in addition to the vessels flying the flag of the United States and other neutral powers are making regular trips across the Atlantic and the products of American manufacture continue to find an export market. The greatest opportunity for expansion in trade is, of course, with Mexico, Central and South America, Africa, and the colonies and nations of the Orient. In the mining industry, the gold mines of South Africa and Australia afford a large market, the silver mines of Mexico, which are beginning to resume operations, will require large investments in machinery and supplies after two years suspension of operations, and the nitrate, tin, and iron mines of South America will all afford increased markets for American machinery. There has been little if any interruption in the Latin-American steamship service; the Ward, Panama, United Fruit, American-Hawaiian, Pacific Mail, Merchants Barber, Norton, United States and Brazil, South American, and other lines are all in operation between North and South American ports, and transportation facilities have been practically unaffected. The recent opening of the Panama canal will greatly expedite the coastwise shipping between North and South America, and with an increased demand from Latin America an excellent opportunity is afforded for strengthening the existing bonds of trade and meeting the increased responsibilities and opportunities which the occasion demands. Americans would be foolish not to take full advantage of the situation.

THE CYANIDE SUPPLY

The present war in Europe is of intense interest to gold miners everywhere, because it seriously interferes with the supply of sodium cyanide, which is so absolutely essential to continuous work that the management of a cyanide plant is always nervous unless there is a considerable supply in stock. Such comfortable assurance is now quite impossible, because in the past few years more than half of the world's supply has been made in Germany, and most of the rest in England. The plants in South Africa drew their supply, in large part, from Germany, and with that source of supply cut off the Rand plants have overwhelmed the two English producers with orders. As the Rand consumption of cyanide amounts to nearly a million pounds per month, the English producers are not likely to be able to do much for the rest of the world. Some years ago three or four American firms began the manufacture of sodium cyanide, but apparently the difficulties encountered were greater and the profits smaller than expected, for the plant of Roessler & Hasslacher, at Perth Amboy, New Jersey, was the only one making any important amount of cyanide in this country at the time the Underwood tariff went into effect. With the removal of the import duty this plant also ceased operations, and since that time all the cyanide used in this country has been imported from either Germany or England. The Perth

Amboy plant was at once reopened on the breaking out of the war, but it has not sufficient capacity to supply the American demand. The owners are naturally loath to expend capital in increasing its capacity in view of the fact that by the time the increased equipment is in normal operation the European war may be over and with the resuming of normal imports it would have again to shut down. In addition, although the modern process of making sodium cyanide by passing ammonia over molten sodium in the presence of coke seems simple, it requires much skill to make a satisfactory product. The product of the reaction is not pure sodium cyanide, but a mixture of salts of varying composition, and unless great care is exercised in the operations the cyanide produced will be of varying strength, thereby causing much annoyance to the cyanide operator, who makes up his solution by weight, adding so many pounds of salt per tank of solution. If the salt is of variable purity the resulting solutions will be of varying strength and, unless tested and corrected, will disarrange the routine of the plant. There is therefore little incentive to chemical manufacturers to undertake the making of cyanide in this country unless they can reasonably hope to hold the business when business conditions again become normal. As far as raw materials go, there is an ample supply in this country, as sodium is produced at Niagara Falls, and plenty of ammonia is available at the by-product coke ovens and gas plants. The relative cost per unit of these here and abroad and the higher wages paid labor here make it unlikely that domestic manufacturers can make enough profit to make it worth while to invest their money in plants for its manufacture here.

Although practically all the cyanide now used is made by the process mentioned above, there are many ways in which cyanide salts can be made. Some of the various cyanide salts and their possibilities were discussed by Mr. D. Mosher in our issue of March 25, 1911 (see 'Cyanide Practice, 1910-1913,' page 27). Of these methods the most promising seems to be the manufacture of low-grade sodium cyanide from cyanamid, which is now manufactured on a large scale at Niagara Falls for use as fertilizer. It is made by passing nitrogen over granular calcium carbide which is heated to the proper temperature by the passage of an electric current. This yields a mixture of $CaCN_2$, free carbon, calcium oxide, and some undecomposed CaC_2. If this material is fed into a bath of molten $NaCl$, the carbon reacts with the $CaCN_2$, forming cyanide, and the resulting product consists of a mixture of $NaCN$, $Ca(CN)_2$, $CaCl_2$, and $NaCl$, which is known by the trade name of 'surrogate.' This 'surrogate' contains the cyanide equivalent of 25 to 50 per cent KCN and can be produced at a cost which enables it to be sold at a price which corresponds to 8 cents per pound of KCN equivalent. This material is not now being manufactured in this country, but arrangements to do so are being made, and it is expected that by December it will be regularly produced in quantity at Niagara Falls, providing the expected market for it can be secured. There seems to be no public records of experiments as to whether this low-grade material can be successfully used as a substitute for pure cyanide, though experience in Western Australia with impure cyanide gives every promise that it can. Where freight costs are important, the increased charges for transport of the 'surrogate' would be to its disadvantage, but as it is much cheaper than pure cyanide this will be offset in many places. It can at least be used as a makeshift until supplies of pure cyanide are again available. Quite a little cyanide is used by fruit growers for killing insects, and for this purpose the cheaper material should be more satisfactory. Cyanide is also used by electroplating plants, but for this purpose the pure salt is essential.

GOVERNMENT OWNED MERCHANT SHIPS

Advocates of government ownership of public utilities now have an excellent chance of testing their theories in practice, since Mr. J. A. Alexander, of Missouri, has introduced in the House of Representatives, with the support of the Administration, a bill to create a $10,000,000 corporation, of which the United States shall hold 51 per cent of the stock, to own and operate merchant vessels engaged in domestic and foreign trade. The corporation is to be directed by a shipping board composed of the secretaries of the Treasury and Commerce and the Postmaster General. The same bill has also been introduced in the Senate by Mr. J. P. Clarke, of Arkansas. Meanwhile Mr. John Wanamaker has proposed, in order to meet the difficulty of providing the necessary funds from an already depleted treasury, that the 30 per cent legal reserve of the $45,000,000 now on deposit in the Postal Savings Banks be invested in the corporation. Leaving aside such obvious and superficial criticism as that navigation of the troubled waters of middle Western politics is doubtless the experience on which the gentlemen mentioned have based their plan for venturing in the wider waters of the Atlantic and Pacific oceans, it will be worth while to consider the essential features of the plan proposed, since, if it is carried into effect it may perhaps serve to indicate the lines along which government ownership of other utilities may finally develop.

The American public is now wide awake to the fact that the shipping of our goods in foreign bottoms and the conduct of our international transactions through foreign banks is a serious handicap to the trade of this country, since the standstill to which our imports and export trade has been brought because of it has served to bring the matter sharply home to everyone. One reason why we do not now have the ships is that a modern steel freighter, costing $1,000,000 to build in England, costs $1,400,000 to build in American shipyards, and in addition to this greater first cost the interest on it and the increased depreciation, insurance, and taxes combine to make its overhead charges so high as to prevent the American ship from operating on an equality of rates with foreign ships. The law formerly

only admitted American built ships to American registry, but it has now been amended so that Americans can purchase ships abroad and register them in this country. This only lets down one bar, however. Our ships have been obliged to employ American officers and a large crew. According to figures given out by a well known New York firm an American vessel of 4500 gross tons burden must maintain a crew of 35 men at wages totaling $1700 per month, while a British steamer of 6000 tons only is required to have 25 men, with a wage list of $850 per month. The cost of feeding the 35 Americans is $550 per month, while the cost of feeding the British is $325 per month. Thus the smaller American ship costs $2250 per month, as compared to $1175 per month for the larger British ship, for wages and keep. It is now proposed to permit the employment of foreigners to man American ships, but as a bill before Congress increases the restrictions in regard to crews, this bar has been only partly removed. Another handicap on American shipping is our method of measurement of cargo in assessing port charges, canal tolls, and other dues. The American basis of measurement rates a ship at 30 to 35 per cent greater cargo space than does the foreign basis. Add to this the inequalities of taxation of the ships owned by American corporations and it is at once seen that the development of an American merchant marine is not a mere matter of buying ships. The Standard Oil Corporation, for example, has not heretofore maintained its large fleet under British and German registry out of mere lack of patriotism, but because the decrease of operating costs by so doing is so great that it cannot afford to do otherwise.

In proceeding to build up a merchant marine, one of two courses of action are available. The conditions under which American ships operate can be made so favorable that privately owned ships will be able to compete on an even basis with foreign ships, or conditions can be left much as they now are and government owned ships can be put in operation and maintained at a loss, if need be, in order that trade generally may have the benefit of their service. Some of the most illogical and unnecessary restrictions already have been or bid fair to be soon removed. It is obviously no more reasonable to force American shipowners to buy their ships in the United States and employ only American officers and seamen than it is to compel American cyanide plants to use American pebbles, instead of Danish, in their tube-mills, or to compel American hotels to employ only American waiters. As a matter of fact it is much less reasonable, for all the cyanide plants and hotels would operate under the same restrictions, while American ships are obliged to compete with ships free from restrictions. Regulations such as these merely indicate that the influence of certain interests at Washington have heretofore been too powerful to permit the interests of the country as a whole to be alone considered in framing legislation. A good start has been made in improving conditions, but nevertheless it may well be doubted whether it will ever be possible to put American shipping upon a basis of equal operating cost with foreign ships. In recent years the influence of labor unions at Washington has been so strong that it is hardly probable that the number of men employed on American ships, or the wage paid to them can be reduced to the basis of foreign shipping. American manufacturers, employing men paid high wages for short hours of work, can compete with European plants using cheaper men working longer hours, because the American manufacturers get a higher output per man, but a ship cannot increase its earnings a single dollar by doubling its crew; it merely increases its operating expenses. For this reason alone it seems probable that the present agitation for the building up of a privately owned merchant marine is not likely to produce much of actual results.

For the same reasons it is equally probable that a government owned merchant marine is not likely to be a source of operating profit. On the other hand, with the government system of bookkeeping, in which depreciation is charged up to capital, it would probably not show much loss. Even if it did, it may be argued that a course of action which is of so much benefit to the country as a whole is a proper field of government expenditure, as amply justifiable as the sums spent to fight insect pests, for the direct benefit of fruit growers, or for maintaining a postal service in districts where the receipts do not meet the cost. Only those who are alarmed at any new proposal, or who object to any increase in the functions of government will see any danger in the proposed plan on this score. A more serious question is whether privately owned ships will be able to continue operations in the face of the low freight charges, coupled with presumably high operating costs, that the government ships are likely to establish as a standard. Somewhat similar objections were made by the express companies when the parcel post was proposed, but so far only one express company has gone out of business, and there is at least room for suspicion that it imitated the Chinese custom of committing suicide on the doorstep of a powerful enemy. Certainly there would be no fewer privately owned ships than we now have. As to whether the service under government ownership would be satisfactory and efficient is hard to tell. There are many drawbacks to government operation of utilities; there are also advantages. A government line could carry its own insurance, at a less cost, and the Federal service has so far been able to ignore workmen's compensation laws. Certainly rates on government-owned lines could not be juggled so as to kill off small but threatening competitors of the big interests. Possibly the present marine service could take on many of the tasks connected with operating a merchant marine at a comparatively small increase of cost. The conclusion of the whole matter is, however, that it seems unlikely that a privately owned merchant marine can be called forth simply by a general public demand ignoring operating costs, and as it is generally agreed that we should now have an American merchant marine, government ownership and operation seems the most feasible way to secure it.

As It Looks in London*

By T. A. RICKARD

A distressing feature of this international war is already apparent, and that is, the natural dislike of everything German. In yesterday's *Financial Times* there was a letter by F. J. Dormer, a man of some standing in the City, urging that the German control of the big South African mines should be ended by ousting these gentlemen from the directorates. He argued that as the shares were held predominantly by English and French people, it was time to make this change. This suggestion has already caused ill feeling to rise to the surface. Of course, most of the South African directors with German names and guttural speech have become naturalized. At the same time, their German affiliation will not be denied. Naturalization is a legal, not an intellectual, process. However, my own detestation of the Potsdam war-crowd, and of the so-called 'intellectuals' that have supported it, is not inconsistent with keen sympathy for German nationals that are victimized by this war. They will suffer quite enough without my raising my hand, or my voice, against them. Among the pitiful incidents to be recorded is the haste of some German professional and business men in London to become naturalized. I don't care to look into the heart or the head of a man who disowns his country in the hour of her need. Personally, just now I am particularly glad that "in spite of all temptations to belong to other nations," despite the greatest temptation of all—to be an American—I am still an Englishman.

H. H. Knox, who was on his way from New York to the Altai, to examine the Ridder mine, has shown me a letter he had sent to the New York *Sun* pointing out that American detachment from this European war may be overdone. He argues that if the Austro-German combination should by any chance triumph, it would mean the annexation of the Dutch West Indies, and a menace not only to the Panama Canal, but to the American nation.

As you know, we have several German advertisements in *The Mining Magazine*. Having received no instructions from the firms concerned, we might assume that their contracts with us continued in force, and as they dealt with purely industrial machinery there seemed no immediate reason to discontinue the advertisements. But there is. By proclamation we are forbidden to do business with the King's enemies or to give them credit; it is high treason to do so; hence we telephoned to our printers at Rugby (90 miles from London) to cut out these German 'ads' and to insert some of our own book advertisements in their place. On trying to telephone to the London agencies of these German firms, we found that they were disconnected. By Government orders all Germans have been taken off the telephone circuit. Of course, after the war there will be a boycott of German products throughout the British Dominion, and the prejudice will extend to many regions not under our flag. I say this to you with no satisfaction, for it is one of the unlovely results of a relapse into barbarism. Whether Germany wins or loses—and I hope that as a military bureaucracy she will be smashed to smithers—it is inevitable that her people will suffer in business.

August 11.

Among the humors of the hour I may record the capture of the scientific expedition sent from Germany to the Crimea to observe the solar eclipse. It is reported that "their scientific instruments of great value have been confiscated." We may presume that the Germans would have done the same if Russian scientists had gone to the Aland islands for the same purpose. No matter, it is more evidence of the gross barbarism to which we have been pushed by the military autocrats.

A. L. Queneau, the zinc specialist, who did good work at Broken Hill, is in the French cavalry. You will find that his address is given in your professional directory as Jemeppe-sur-Meuse, in the heart of the Belgian cockpit. He is a Columbia graduate. His wife and four children are at Liége. May his sword-arm have the strength of ten! Another zinc specialist is H. M. Ridge, of London, who happened to be on the continent at the outbreak of war and is now 'detained' at Düsseldorf. We have heard from him that he is well, but under surveillance. It is a pity, for the schemes on foot for starting smelters to treat zinc-lead concentrate would gain from his knowledge in this branch of metallurgy. He speaks German fluently and likes the people, so that he will probably escape harsh treatment.

Gilman Brown has arrived from Russia. He was 8 days on the way from St. Petersburg to London, his itinerary being Raumä, in Finland, thence to Stockholm, then by train to Bergen (through Christiania) and so to Leith in Scotland, and by train to London. He underwent no hardships. The Russians, he says, are enthusiastic. Twelve million uniforms are ready for use. Even the Finns are coöperating loyally. At the big copper mines at Tanalyk, Kyshtim, Spassky, and Atbasar, the mobilization has withdrawn 30 to 40% of the employees, necessitating a cessation of development work. But production of copper continues, stimulated by the domestic demand and the import duty (equivalent to a bounty), so that the effective price for the metal is £103 per ton. The Kirghiz, being nomadic, are not called to the colors, so that they afford a valuable labor-supply. H. H. Knox and E. J. Carlyle are leaving at once, by way of Norway and Finland, to go to the Ridder and the Sissert mines, respectively.

Aug. 25.

*In this series of war letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies, but he will endeavor to be as impartial as he may.

FIG. 1. DISTILLATION BUILDING, ACID PLANT, STORE-ROOMS, AND POWER-PLANT.

The Rose Lake Smelter of the Granby Company

By E. H. LESLIE

Among those companies which have been conspicuously identified with the development and advancement of lead and zinc smelting, the Granby Mining & Smelting Company holds a most enviable and patriarchal position. Incorporated in 1865 by Henry T. Blow, Peter E. Blow, James B. Eads, the bridge builder, and Charles K. Dickson, the Granby company acquired the business and mining interests of the firm of Kennett & Blow which had been operating lead properties in Newton county, Missouri, for a long period previous to and during the Civil War; having thus laid its foundations in the beginnings of the industry, a superstructure has been raised which is both a credit and monument to the builders. The Granby company has been in active business for a period of 49 years, and application has been made to the Secretary of State of Missouri for a renewal of its charter for a period of 50 years, beginning April 5, 1915. The officers who have directed the affairs of the Company for a number of years past are president Elias S. Gatch; vice-president, Norris B. Gregg; secretary, Kennett Burnes; treasurer, Elias S. Gatch; who together with James H. Grover, and Howard O. Edmonds, comprise the board of directors.

Suitably to commemorate the 50 years of successful mining and smelting activity and meet the expansion of its business, the Company purchased 148 acres of land, just outside of the city limits of East St. Louis, and adjacent to the right-of-way of the Vandalia and Terminal tracks, for the site of a zinc smelter which would fitly characterize the stability and progress of this concern.

The Rose Lake smelter has been laid out and designed with a view of obtaining the most modern equipment and best practice which the industry affords, and toward attaining this end the Company has spared neither time nor expense in the erection of a smelter which embodies the most modern methods and mechanical equipment. Before ground was broken for the smelter, the president of the Company, Elias S. Gatch, and the chief engineer made extensive trips throughout the zinc-smelting districts of the United States and Europe to study the latest and best of the world's zinc smelters, and this, together with the Company's experience and the best engineering talent available, has resulted in the present

FIG. 2. POTTERY, POWER-PLANT, ROASTER BUILDING, AND STORAGE HOUSE

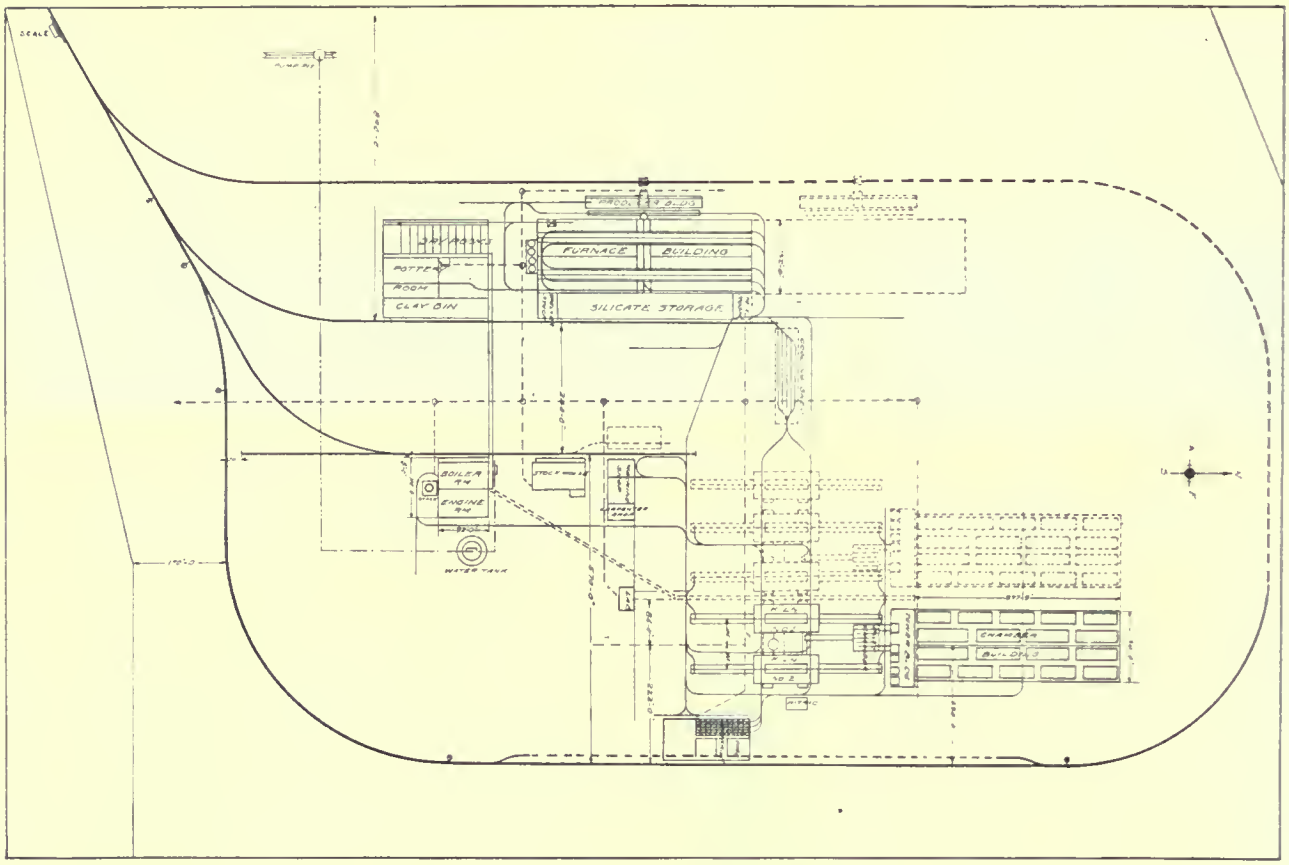

FIG. 3. PLAN OF THE ROSE LAKE SMELTER.

plant. Before deciding on the erection of this smelter, the Company purchased 10,000 acres of coal lands in Bond county, Illinois, about 50 miles distant from the smelter, which guarantees a fuel supply for many years to come. The engineering work was done largely by the firm of Ruebel & Wells in coöperation with the Company's staff. The concrete and brick work was let to the James H. Bright Contracting & Building Co., and the steelwork was supplied and erected by the American Bridge Company. While the metallurgical practice as planned for this plant is the standard practice of producer-gas smelters, there has been a number of departures in the general layout of the plant in construction, and in mechanical equipment which makes it novel in many respects.

PLAN OF THE SMELTER

The topography of the site is almost level, with a few depressions which will later be filled with retort residues as the work progresses. The plan of the buildings and grounds of the smelter is as shown in the accompanying plan, Fig. 3, solid lines indicating buildings which comprise the original plant, while the dotted lines represent buildings which will later be erected as the initial capacity of the plant is increased. Besides the standard-gage track, which is as shown in the plan, there are several miles of industrial track for the handling of furnace materials and supplies. A study of the plan cannot fail to impress one with the orderly arrangement of the various buildings and departments. The halftones, Fig. 1 and Fig. 2, show general views of the smelter and the stability and permanence of the construction, a feature in marked contrast to the natural gas smelters of the Middle West. It will be noted that the construction is entirely of concrete, brick, heavy corrugated iron, and steel. As with the new producer smelters, the excavated type of furnace structure has been abandoned, the furnace floors being elevated permits better ventilation and greater efficiency in the handling of furnaces.

CONCENTRATES TREATED

The concentrates to be treated, when the smelter is placed in operation, will be derived largely from the Company's mines in the Joplin district. These concentrates will be delivered at the plant in the standard-gage cars at the ore-storage building, which is 100 by 150 ft. in dimensions. The cars enter this building over a 5% grade and are mechanically discharged into a Bartlett & Snow rotary dryer. As the cars enter the grounds they pass over a track scale which is situated near the entrance to the smelter grounds, as shown in the plan. Here the concentrates and fuels are weighed and a check kept on all raw materials. The storage shed is equipped with Power & Mining Machinery Co.'s crushing rolls, Bartlett & Snow Co. 40-ft. rotary dryer, and two Newwaygo separator screens. The material after being dried passes to the rolls and screen, the oversize being returned and the final product which passes 2 mm. is elevated and conveyed to the storage bins by

FIG. 4. CHAMBER BUILDING, ACID TOWER, AND ROASTER BUILDING.

Stevens-Adamson machinery. The bins are of steel and suspended over industrial tracks, and have a capacity of 5000 tons.

The concentrates are drawn from the bins into industrial cars, which are of 2½ tons capacity, and top hearths. The initial roasting plant consists of two separately housed modified Hegeler roasting furnaces. The acid plant and one of the roaster buildings is shown in Fig. 4. The plant is laid out for the erection of three additional roasters when needed, which will be

trammed to the roasting furnaces. Here they are elevated to bins placed above the feed-end of the furnaces from which they are automatically discharged into the situated as shown in the plan. These furnaces are 22 ft. wide, 32 ft. high, and 84 ft. long, with 7 hearths. This type of muffle furnace has come to be recognized

as standard in zinc smelting practice where a sulphuric acid plant is a part of the equipment as an exceptionally pure and clean gas is obtained from this furnace. An idea as to the construction of a Hegeler type furnace may be obtained from the accompanying drawing, Fig. 5. The furnaces consist of seven hearths and only the lower three hearths are heated by producer gas. The hearths are arranged with muffles on each side of the centre wall, the concentrate being fed in at opposite ends of the two top hearths and discharged at the two opposite ends of the bottom hearths. The passage of the blende through the muffles is effected by means of the rabbling mechanism. Rabbling is commenced at the top hearth, the charge being moved from the feed toward the discharge end where it is dropped through a slot in the floor of the hearth upon the hearth below. It is then drawn by another rabble toward the opposite end, where it is again dropped through another slot to the next lower hearth. The ore is thus drawn through the furnace by the rabbles and discharged from the lowest hearth of the furnace. The rabble used is of the ordinary rake type, so designed as to turn over, plow, and move forward the charge as it moves through the furnace. The rabbles are supported on a stand at the end of the furnace which may be revolved from one side to the other for the rabbling of each of the two hearths on each floor level. The rakes are drawn through the furnace by detachable rods with an improved driving mechanism. The gas travels in the opposite direction, being admitted to the lowest fire muffle at one end it passes to the other, being partly burned by the admission of air at intervals. The gas then passes outside of the muffle and is admitted through a by-pass to the next muffle above, where it is further burned, the combustion being finally completed under the third muffle. The hearths are closed at the ends by sheet iron doors which are hinged at the top and automatically opened and closed by the passage of the rabbles through the furnace. These furnaces have a capacity of 50 tons per day.

Fig. 6. Acid towers.

A ten-foot Chapman gas-producer supplies gas for both the roasting furnaces. The Chapman producer is manufactured by the Chapman Engineering Co. of Cleveland, Ohio. It is a mechanically operated producer consisting of two revolving parts. These parts revolve in the same direction at different speeds, resulting in a twisting motion in the fire zone, thus keeping the fuel from clinkering. The residue is broken by the revolving action of producer, grinding it against the corrugated surface of the tuyere frame. The ashes are automatically ejected by the motion of the producer. The coal used in this producer is delivered in industrial cars and elevated to a superimposed steel bin above the producer.

Acid Plant

The sulphuric acid plant is one of the most important parts of the smelter and will be seen immediately at the rear of the roaster building, Fig. 4. The chamber building, also seen in Fig. 4, is of most modern construction, is 130 by 360 ft. in dimension, and is built entirely of structural steel, corrugated iron, and concrete. The working floor is of steel and is 15 ft. above the ground to permit of good ventilation. The truss line from which the chambers are suspended, as the lead chambers will not admit of compression, is 24 ft. above the working floor. The gases from the roasting furnaces pass through the dust chamber and into the tower building which is a part of the acid plant. This department consists of two Glover towers and three Gay-Lussac towers. A view during construction is shown in Fig. 6. From the Glover towers the gas passes through the two systems of lead chambers, and from these chambers it is returned to the three Gay-Lussac towers, through which it passes in series and is finally discharged into the air. The weak acid produced in the chambers together with a small amount of nitric acid, which is required to produce the nitrous oxides which are necessary in sulphuric acid manufacture, enters at the top of the Glover towers and passing through them is returned to the system of Gay-Lussac towers through which it passes in series. It is then returned to the two Glover towers for concentration. Here the weak acid or water which is added is

converted into steam, which when passed into the chambers supplies a part of the steam necessary for the chamber part of the process, and the acid thus concentrated is again ready for reabsorbing nitrous acid gas in the Gay-Lussac towers, while the excess which is the major part is ready for the market or further concentration. The circulation of gas through this system is accomplished by means of two fans between the Glover towers and the chamber systems, and one fan between the first and second Gay-Lussac towers. The flow of the gas and acid through the plant is shown by the accompanying diagrams, Fig. 7 and 8. The matter of ventilation, as previously mentioned, has been given particular attention in the construction of this plant. In addition to floor gratings, there are, at the top of the building, 120 sashes which are automatically controlled by the action of a wind vane and a motor. The two sets of chambers are made up of nine chambers each. These chambers are of different sizes and arranged in series.

The connection between the roasting furnaces and chamber system for the transfer of the gases has been so arranged that by the opening and closing of gates the two furnaces and the two chamber systems may be operated separately or in series. In this manner the gas supply to the acid plant can be carefully regulated. The nitric acid which is used in the manufacture of sulphuric acid at this plant, is manufactured in a separate building on the grounds by the Valentinier process, the feature of which is the distillation under a vacuum. The sulphuric acid to be produced at this plant will be of a strength of 60° Baumé which is the standard grade manufactured by the chamber process.

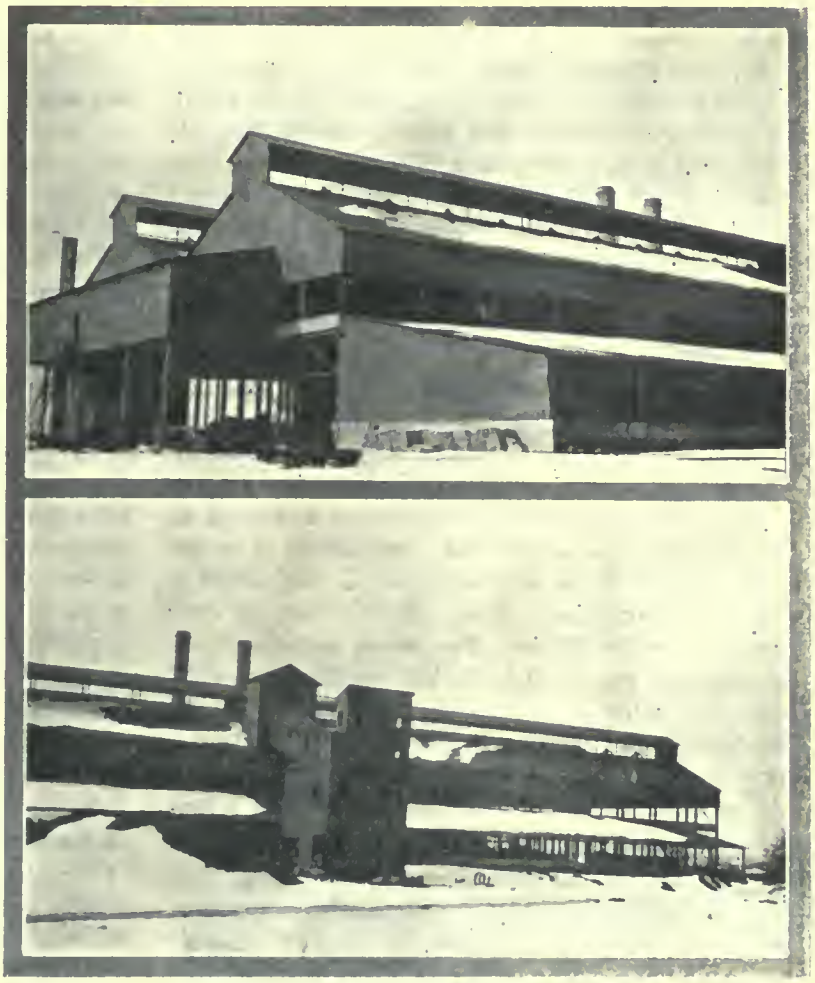

FIG. 9. DISTILLATION FURNACE BUILDING.

DISTILLATION FURNACES

The four blocks of retort furnaces are housed in one

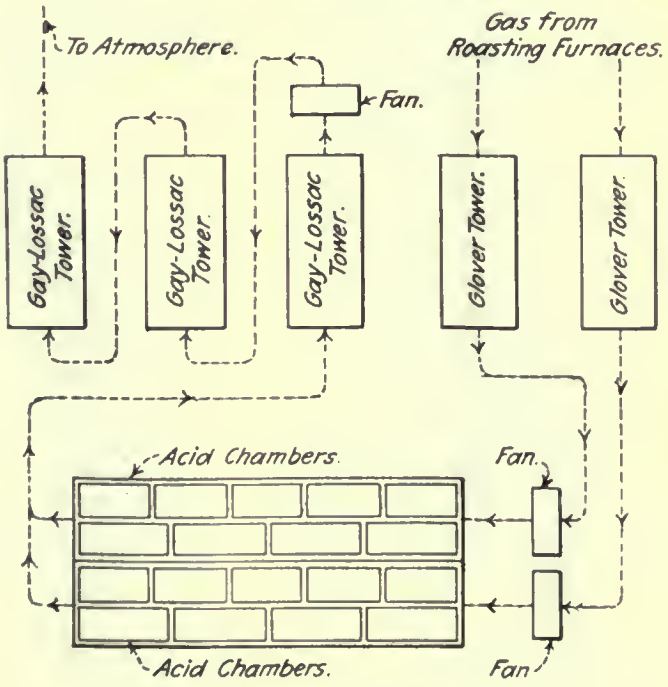

FIG. 7. FLOW OF GAS THROUGH ACID PLANT.

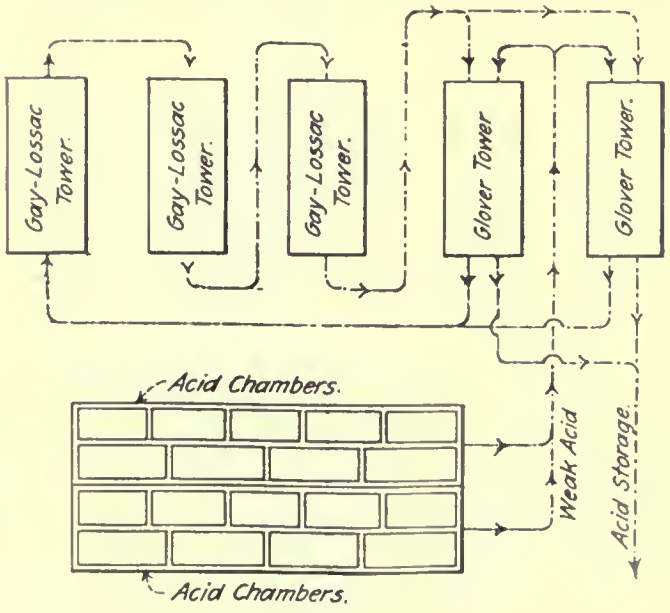

FIG. 8. FLOW OF ACID THROUGH ACID PLANT.

building which is situated to the west of the roasting kilns and acid plant and connected with it by industrial tracks. The construction and arrangement of this building is as shown in Fig. 9 and plan of the smelter. It will be noted that the elevated floor type of structure has been adopted and that every detail of construction has been carefully planned. While the initial plant will consist of four blocks of furnaces, the arrangement is such that a similar number can and will be added at some time in the future. The furnaces are fired by producer gas.

The mixing room is centrally placed at the east side of the furnace building, as shown in the plan. Here the roasted concentrate from the storage bins in the cooling shed is brought and automatically weighed. The fuel, carbonate, and roasted sulphide are mixed in an 80-ft. Milwaukee concrete mixer, from which it is discharged upon an 18-in. belt-conveyor and conducted to the charge storage bins. There are two bins for each of the four smelter blocks. The mixer is driven by a 50-hp. Sprague motor, and the belt-conveyor by a 15-hp. Sprague motor.

The fuel for the furnaces is supplied by 12 Hughes gas-producers arranged in two batteries of six each, as will be seen in Fig. 10. The coal is unloaded by a loco-

FIG. 10. PRODUCER PLANT FOR DISTILLATION FURNACES.

motive crane or dumped directly into the hoppers of an apron conveyor. This discharges into a Jeffry single-roll crusher. The crushed coal is then elevated by a bucket-elevator and discharged upon a conveyor which transfers the coal to the bins over the producers; Stevens-Adamson conveyors are used for this purpose. This reversible conveyor, for the distribution of the coal to the bins, is mounted on a carriage which moves over a track above the bins. The conveyor carriage is operated by the same motor as the 24-in. conveyor-belt, and is moved in this manner into position to discharge into any of the 12 coal bins. These bins are of the suspended steel type and are fitted with concrete divisions to take up the dead space between outlets of the bins. These bins have a capacity of 90 tons each. One man will operate the crusher and coal-distribution system. The power for handling the coal consists of one 10-hp. Sprague motor for the distributing conveyor, one 10-hp. Sprague motor on the elevator, and one 15-hp. Sprague motor to drive the coal crusher and apron conveyor.

The coal from the bins is discharged directly into the bell sealed hoppers of the Hughes gas-producers, which are connected with one main header. As previously stated, the 12 producers are divided into two batteries of 6 each and each battery is driven by a 30-hp. motor. Each producer gasifies 18 tons of coal per 24 hours.

The four blocks of regenerative distillation furnaces are arranged in rows of two each. The furnaces and the building are laid out so that charging machines may be installed without alterations. The gas and air enter ducts in the bottom of the furnace through large Swindell valves, travel the length of furnace through the ducts, and enter the furnace from these ducts through a system of checkerwork, absorbing heat therefrom, and after burning in the furnace travel to the stack through corresponding checkerwork and ducts, leaving the heat to be taken up by the air and gas on the reversal of valves at stated intervals.

The furnace blocks are 108 by 18 ft. in dimensions. The retorts are placed in five rows with 15 retorts to the section. There are 27 sections to the side of a block, thus making 405 retorts to the furnace or 810 retorts to the block. The original plant will therefore contain 3240 retorts. Each block is fitted with a Wiederholdt chimney 80 ft. high.

The charge is drawn from the storage bins into the charge cars, and moved to the front of the furnace, where it will be charged by hand into the retorts. The drawing is effected in the usual manner by means of a draw car with a ladle suspended in it and operated by a hand winch. During drawing operations the operator is protected from the heat of the furnace by means of a sheet-iron shield. The metal thus drawn is cast in molds and removed to the spelter stock room by a gasoline locomotive. The discharging of the retorts is accomplished by means of scrapers, the usual method in the Illinois field. The retorts are 52 by 9 in. inside dimensions. When in operation the plant will have a capacity of 100 tons sulphide concentrate per 24 hours.

The furnace floor is 20 ft. above ground level, which type of structure has been adopted by the more modern smelters. The hot residue falls by gravity through chutes at the front of the furnaces into hoppers in the sub-structure. The hoppers discharge into industrial cars in which the residue is removed to the dumping ground. The residue, together with cinders from the gas-producers and boiler plant, will be used for the filling of depressions in the grounds around the buildings over the entire tract, as the present surface is from 3 to 7 ft. below the established grade. At such a time as necessity demands, there is an area of several hundred acres adjoining the property on the north which is 20 ft. lower than the level of the smelter grounds and will furnish a dumping ground for many years to come.

POTTERY

The pottery plant, in which the retorts and condensers are manufactured, is complete in every detail and em-

bodies mechanical features which make it noteworthy in many respects. This building, which is seen at the left in Fig. 2, is a pressed brick and reinforced concrete structure. The clay and adobes are delivered on standard-gage cars at the plant and unloaded into bins at the side of the pottery. The crushing plant consists of a Williams hammer crusher which is driven by a 50-hp. Sprague motor. The discharge from the crusher falls upon a belt-conveyor and is conducted to the foot of a bucket-elevator by which it is elevated to a ⅛-in. Newwaygo screen. The oversize is returned to the crusher. This screen is actuated by means of a cam-shaft which gives it a vibratory movement and is fitted with a screw feed. The under-sized material from the screen falls into a reinforced concrete storage bin. The clay, adobe, and crushed retorts are stored in separate bins and drawn from them as needed into a large steel bucket which is suspended from overhead rail, and in this manner taken to the wet pan for mixing. The pan used is 9 ft. in diameter, built by the American Clay & Machinery Co. The clay, as it emerges from the wet pan, is allowed to season for several days and is again given another kneading in the pan. After this, it is passed to the W. C. Raymond ball-mill, from which it is subsequently removed to the retort press. A Wettengel hydraulic retort press is used for the moulding of retorts, pressure for which is furnished by a four-cylinder pump and accumulator. The condenser mixture and looming material for the furnaces is mixed and pugged in an American Clay & Machinery Co. combination pugging and ball-mill. This is fed direct from the bins. The condensers are made in a Garrison & Whipple, Cheeryvale, Kansas, condenser machine, which has a capacity of 1000 condensers per day. Power for the entire pottery plant is furnished by a 100-hp. Sprague motor.

Dry-Rooms

The retorts as removed from the press are taken to the 12 dry-rooms for subsequent treatment. The construction of these rooms is of a special interest and forms an important part of the pottery plant. The rooms are opened at both ends by ice-box doors which make the rooms practically air tight. In filling the rooms, the retorts are taken in through the doors on that side adjoining the pottery room. When the retorts are removed they are taken out through the doors at the rear or opposite end of the rooms. In this manner the first retorts to be placed in the drying-rooms are the first to be removed. The air used for drying is heated by exhaust steam from the power plant, it being brought from the power-plant to the pottery through pipes in a concrete conduit. At the pottery this steam circulates through coils of ¾-in. pipe which are in a steel housing, and the air is drawn through this chamber in which the steam coils are placed by means of a Siroceo fan. This fan is driven by a 7½-hp. Sprague motor. The air thus heated passes through sheet-iron conduits to the dry-rooms. It enters at the top of the rooms, passes through the retorts and out at the bottom of the rooms through another conduit. The air from the dry-rooms is conducted to the workroom of the pottery and is used for heating it in the winter time, while in the summer time it is discharged outside of the building. The pressure on the dry-rooms is kept at about 2-in water gauge. This is regulated by means of valves in the discharge air passages of each room. These valves are opened or closed from the outside of the room by means of a chain near the rear doors. The roof of the dry-room section of the building is made of hollow tile and reinforced concrete, thus affording a dead air space which has been found to be very beneficial in the prevention of condensation, especially in the winter time.

The condensers are made from a half-and-half mixture of clay and old retorts, and are dried and burned in especial kilns for this purpose. The retorts are removed from the dry-rooms on flat trucks and trammed by a gasoline locomotive to the furnace building. The tempering kilns, of which there is one for each block of furnaces, are especially designed circular beehive kilns made for down draft. These kilns are fired with coal.

Power-Plant

The power-plant is one of the features of the smelter and has embodied in its equipment and construction the most modern of machinery and appliances. The boiler plant consists of three 350-hp. Babcock & Wilcox, marine type, steam boilers. These boilers are fitted with Bayonne stoker attachments. In planning the boiler-room, provision has been made and the foundation is in for an additional boiler unit. The boiler-room equipment also includes a Sorge-Cochran water heater and purifier and two Epping & Carpenter boiler feed pumps.

The two power-units are 600-kw. Sprague generators, direct connected to Fulton-Corliss engines. Space and foundations have also been left for an additional unit as occasion requires. The switchboard is of Vermont blue marble made by the Frank Adams Electric Co. A Bowser gravity oil system and filter has also been installed. By this system all the oil is collected in a tank in the basement and pumped by air to the filter and storage tank in the engine-room above. The machine includes a water separator and oil purifier.

The fire pumping plant consists of an Alberger 2-stage 1500-gal. pump, driven by a 150-hp. motor. This pump is controlled from the engine-room. The equipment also includes a 700-ft. Chicago Pneumatic Tool Co. air-compressor. The water-supply for the smelter comes from two 90-ft. wells, and is pumped into a 120,000-gal. steel storage tank which is 140 ft. above the ground, as shown in the general views of the plant. The pumping plant consists of two 350-gal. Alberger, direct-connected, turbine pumps placed at the wells. A gauge-board in the engine-room records the height of water in this tank. Electricity is conducted to the various departments of the smelter by lead-covered cables through concrete underground tunnels. No overhead wires are anywhere in evidence about the smelter grounds. The exhaust steam from the engines and pumps is also conducted through

these tunnels to the various departments for heating purposes.

Machine Shop

The machine and carpenter shop is a pressed brick building on a siding of the standard-gage track, and is amply equipped to meet all the requirements of the smelter. The equipment includes a band-saw, a cross-cut saw, a pipe machine, a metal-breaking machine, a 16-ft. lathe with a 26-in. swing, a 30-in. planer, a shaper, a radial drill-press with 36-in. swing, a small drill-press, a combination punch and shear, a triphammer, small punches and shears, a bolt machine, a pipe-cutting machine, a set of rolls, and emery wheels. All of the machines are driven from a line shaft by a 15-hp. Sprague motor. There are also two forges operated by direct-connected blowers which are driven by small Sprague motors. The tool-room, which is a part of the machine-shop, is stocked with a complete supply of all kinds of tools for use about the smelter.

The laboratory is a small pressed-brick building completely equipped for the analysis of smelter supplies and products. For grinding samples, a small jaw crusher and Braun planetary pulverizer, which are driven by a 3-hp. motor, have been installed. There is also a steam dryer for drying samples. Water for laboratory uses is distilled in a steam still manufactured by the Stokes Machine Co. The routine laboratory is equipped with a hood, electric hot plates, and the most modern of analytical apparatus. There are two well equipped balance-rooms and a store-room for glassware and laboratory supplies. An emergency hospital room is provided in this building, where first-aid work can be administered. There is a research laboratory room in addition to the routine room, fully equipped for research and special work.

The store-room is a two-story, pressed-brick, semi-fireproof building which is 50 by 96 ft. in dimensions and is heated with exhaust steam from the engine-room. About $10,000 worth of smelter supplies are kept on hand in this building. A sewage-disposal system has been installed at the plant at a cost of $10,000. No effort has been spared to provide the most sanitary buildings and care for the comfort and health of the employees.

The plant as it stands today represents an outlay of $1,500,000, and when put into operation will represent one of the most advanced practice and complete mechanically equipped smelters in this country. As a monument to the executive ability and engineering skill of the Granby company, the Rose Lake smelter reflects great credit to this organization, and the shareholders are to be congratulated upon this latest addition to their holdings.

Mining District of Pinos Altos, New Mexico

By W. ROGERS WADE

This district is situated in the northeastern part of Grant county, New Mexico. The postoffice for the camp is Pinos Altos and is reached by an eight-mile stage drive from Silver City, which latter point is on the Atchison, Topeka & Santa Fe railroad. The town lies at the base of the Pinos Altos mountains at an elevation of 7000 ft., while the peaks themselves reach about 8050 feet.

Placer gold was the first discovery in the district, in 1860, by a Mr. Birch, a California pioneer. Lode mining commenced soon after and the first vein to be worked was the Pacific. Within the next two years several hundred men were at work in the camp and over 25 veins were developed. In 1896 the Hearst estate of California became interested, and operated the Hearst and Gillette shafts on the Pacific mine. Later, in 1903, these were sold to the Comanche Mining & Smelting Co. This latter concern built a smelter at Silver City and a narrow-gage railroad to Pinos Altos. It went into the hands of a receiver in 1908, and the property now belongs to the Savanna Copper Co. The district has produced about $5,000,000 in gold, silver, and copper. Some of the ore has been exceedingly rich.

The Pinos Altos mountains appear to be an intrusive mass several miles in diameter. The intrusive has penetrated through beds of quartzite, limestone, and sandstone, and tilted these beds sharply to the west. A part of these beds is to be seen on the western side of the mountains and strike northerly, dipping west.

The tops and eastern sides of the mountains are composed of granodiorite (locally called granite) and diorite. The granodiorite appears to be the older of the two. It shows a porphyritic structure northeast of the town. The diorite is dark greenish in color and forms the central part of the peaks. The granodiorite forms the eastern part along the base. The diorite appears to have come up through the granodiorite. Both rocks are closely related and probably of nearly the same geological age. Judging from similar formations in other parts of the state, they are early Tertiary.

The western part of the district has some extensive zinc orebodies in the limestone. This article will be confined to the gold-silver-copper veins in the igneous rocks.

The oldest vein system which I observed strikes east and west, and is very indistinct, being really a series of crush zones, generally narrow. Next followed a north-south faulting with a dip from 65 to 75° to the west. This faulting opened channels for mineralization, and quartz, chalcopyrite, pyrite, zinc-blende, galena, gold, and silver ores fill the fissures. The Langston, Pacific No. 2, and Pinos Altos workings are on one of this

series. This system was then faulted by two series of faults, one striking N. 60 to 65° E., and the other northwest. The N. 60° E. faults throw the north-south veins from 6 to 20 ft. horizontally. In several cases these N. 60° E. faults have opened fissures which have been mineralized with gold, silver, copper, lead, and zinc ores in a quartz gangue. The Gillette and Hearst workings are on one of these N. 60° E. series.

In other cases, parallel faults of this series are not mineralized. These N. 60° E. faults and veins either are vertical or dip about 80° to the northwest. Lastly, there has occurred the northwest-southeast faulting mentioned before. I have not observed any mineralization along this system and believe the faulting occurred after the mineralizing activity had ceased.

Mineralization

Mineralization in the district was caused by ascending solutions. Most of the veins were apparently open fissures. Quartz was first deposited on each wall with the tips of the crystals well formed and pointing inward. Next the deposition was more rapid, and a mixture of quartz and metallic sulphides filled up the remaining space. The upper portions of the veins are now oxidized, with the result that the zinc is leached out and the gold enriched. This oxidation extends from 50 to 150 ft. below the surface.

There seems to have been considerable enrichment at points on the veins where they are cut by cross-faults. In the case of the Pinos Altos lode in the Pacific No. 2 claim, this north-south vein is cut by a N. 65° E. fault. The displacement of the lode is 17 ft. on the first level and 6 ft. on the second. The fault dips vertically, or practically so. At the point where it crosses the vein there seem to be the remains of an east-west fissure, so that three breaks meet at a common point. The east-west vein has been displaced by the north-south fissure and the latter faulted by the N. 65° E. fault. The result is that the only evidence of the ancient east-west vein is a quartz and copper sulphide filling, the crystallization and banding of which is at right angles to that in the north-south vein. I observed this filling on the 130-ft. level in the Bell and Wright workings at the intersection of the fault and the vein. It was only about a foot wide, both ends being cut off by the foot and hanging walls of the north-south vein.

As a result of the faulting, a notable enrichment has occurred on the intersection, the ore having risen in value from $30 to ore so full of gold that it assays up to $25,000 per ton. The ore was many times above the general mine average for distances of 20 to 25 ft. from the fault on the south side, all the way from near the surface down to the 230-ft. level, at which point the ore at the fault became shot full of free gold. A winze sunk on the vein for a distance of 30 ft. below the 230-ft. level is said to have produced $40,000 in high-grade ore. This winze is 3 by 5 ft. in size. The rich ore was found on the 230-ft. level about two feet above the floor, and was reported to me to be three feet long, eight inches wide, and to extend to the bottom.

The veins in this camp being all practically similar in character, the various mines operate about the same way. I will describe the practice as I observed it in the Pacific No. 2, or Bell and Wright lease.

The main hoisting shaft is an incline sunk on the vein. It is timbered on the hanging wall and the two ends. It is of one compartment only. Hoisting is done in buckets with a friction geared hoist belted to a two-cylinder, two-cycle, Gray gasoline motor. Levels are turned about every 100 ft. as measured down the incline. The vein dips 66° and averages 10 in. wide. The walls are diorite, much shattered next to the vein, considerably altered, and full of gouge. All drifts are generally timbered. Stoping is done overhand, stulls being put along the top of the drift and no pillars left above the level. These stulls are placed close together and covered with lagging. Chutes are carried up through the stopes every 50 ft. and provided with a gate at the bottom to draw the ore.

The hanging wall rock is first shot down and left to fill the stope. After exposing the vein for 10 to 15 ft. along the roof and about 3 ft. high, canvas is laid on the waste and the vein is then mined out. It is then shoveled from the canvas into the ore chutes. By keeping the stope narrow so that, say, two and a half feet of hanging wall waste is broken to ten inches of vein mined, the waste left in the stope can be adjusted (due to the greater volume of the rock when broken) to just fill the space mined and be kept up to the working back without hoisting any waste.

The ore is drawn from the chutes and hoisted to the surface, where it is sorted into different grades, the idea being to get out the zinc if possible.

The cost of mining and sorting is about $4 per ton. The cost of development runs about $1 per ton. The wagon haul to the railroad at Silver City is $2 per ton, and the freight to the El Paso smelter is $1. The treatment charges average $7 per ton. Gold is paid for at $19.50 per ounce; silver, 95% assay at New York price; copper at 2½c. below New York price, to allow for costs. Over 12% zinc is penalized.

Future of the District

Operations of recent years have been small and mostly by lessees. The only available ores have been those high grade enough to ship direct to the smelter. The rich find recently made by Bell and Wright has encouraged much activity, and nearly all the properties are now being worked by small companies or by lessees. The real future of the camp is dependent on concentration. The ore below 200 ft. is all sulphide and contains generally less gold and increased amounts of zinc. The great difficulty is to separate the lead, copper, and iron sulphides from the zinc sulphide. The gold seems to be associated with the iron pyrite. Operators at present believe from test runs that this can be done with the Huff separator with success. If this works out commercially, the district will enjoy a long life.

Prospecting on the Upper Magdalena

By C. S. HALEY

Recent developments on the Cauca river, chiefly due to the operations of Oroville Dredging, Ltd., but also in part to the work of a few smaller companies, have attracted the attention of mining people to Colombia, with the result that in the last year several parties have been sent out, from both sides of the Atlantic, with the object of investigating dredging ground.

Early Conditions

It is, of course, from the latter standpoint that Colombia is interesting to gold miners. While in the early days of Spanish colonization the workable surface placers were numerous and in some places very rich, everything that was at all accessible to water in a country which is noted for the abundance of its rivers and the frequency of its rains, was ground-sluiced on a large working scale as soon as its value was discovered. As labor was fairly abundant and under the Spanish system cost nothing; food for the peons grew in a naturally prepared state on the grounds; and working tools for ditching and mining could be manufactured by hand from the heavier woods, with the use of a little iron, it is rather difficult to see just how the working cost could be calculated. Probably the most important element consisted in expenditure for powder and ball shot to be used against the cheerful English buccaneers.

At any rate, working conditions being so ideal from the operators standpoint, and the demand for gold being so acute in the mother country it is little wonder that all of the placers which could be handled were worked, and that right rapidly. However, there remained the deeper bars of the larger rivers, which were absolutely impossible to work by hand, and which were foreordained to retain their value (when they had it) until the introduction of modern machinery.

While the chief centre for gold during colonial times was probably on the Cauca and its tributaries, as well as the rivers of the west coast, nevertheless the upper portion of the Magdalena, lying directly east of what is known as the Cordillera Central, contributed its share, as well as a larger proportion of silver than its neighbors on the west. It is this area that is shown on the accompanying map, and historically it is perhaps of greater interest than any other portion of Colombia. Here it was that the knighted pirates of the Caribbean penetrated in their search for the Castilian goose that was monthly furnishing the golden egg for the treasure trains of Bogota; sailing their little cockle shells up the wide and muddy bosom of the Magdalena, and flaunting their black and white flag of death and destruction under the very faces of the Spanish slave drivers in the heart of their own country.

The rough and truculent business methods of those times have passed away; the spirit of modernity has so far encompassed this, as most other of the far corners of the earth, that where one boatload of swarthy pirates levied their toll upon the land at monthly intervals, whole squadrons of steamers plying up and down the river every week now exact dividends of 50% and more per annum.

As everybody knows, Barranquilla, near the mouth of the Magdalena, is reached by railroad from Puerto Colombia, some twenty miles west, which is the port of entry for the former town. The Hamburg American, the Royal Mail, and the United Fruit companies all make connections there, as well as several European boats. So far as I know, the service from New York is excellent on all three, and food and comfort are all that could be desired. The trip from New York to Puerto Colombia requires about eleven days.

Arrived at Barranquilla, the first thing to be attended to is the passing of luggage and personal effects through the customs. Accommodations here are much better than down in the west coast ports of Peru and Chile, and, so far from meeting with hostility from the Colombian officials, I have found them to be thoroughly courteous, expediting matters as far as lay in their power. In general throughout the country, in fact, I was agreeably surprised, after what I had heard, to notice that the attitude of the people was decidedly friendly. In talking with several of the younger generation, from 20 to 30 years old, I frequently found them expressing a desire to go to the United States and see for themselves the results of an enterprise for which they express the most sincere admiration. It seems to be the idea of many of the leading business men to send their children here, after learning English in the Colombian schools. The result is that there is a great demand for English teachers.

Transfer to Steamer

After getting everything through the customs, your effects are transported on two wheeled carts over to your steamer on the 'dique.' This latter, named from the dock built upon it, is a small bayou or arm which runs from the Magdalena up to the city, and is deep enough for the passage of all river steamers. It is usually full of flat bottomed river boats of all sizes and conditions, loading and unloading coffee and merchandise of all sorts, hides, live stock, sugar, corn, and a multitude of other things, including the omnipresent banana, the staple food article of the country. Swarms of swarthy *cargadores* are scurrying here and there with their heavy loads upon their backs, and one can with difficulty walk without stepping on their bare feet.

The first question that confronts you is that of which boat you want to take. The express boats, sailing with the mail weekly for La Dorada, Girardot, and Bogota,

leave every Friday. Being ready to leave on a Monday, say, the average man prefers to take an intermediate steamer of that date, not caring to waste his time in waiting. As a result of his haste, especially if the river is low, he will find himself loafing leisurely along the lower river, stopping every mile or two to take on a few cattle, or an old woman with a basket of eggs, and may eventually find himself stuck on a mudbank with his heavily cargoed boat, watching the express boat, which, though leaving four days later, comes direct stopping only when necessary to take on wood or deliver mail, flaunt merrily past him. For all upriver destinations, especially above La Dorada, it is much better to wait and take the express boats, as it saves time in the long run, and makes the trip even more comfortable.

River Travel

The river steamers themselves are rather surprisingly comfortable, even the intermediates. The food, prepared in Colombian style, is appetizing, though of course one should keep away from the kitchen. Beds are simply canvas cots occupying about half of each stateroom. In addition to bedding, the traveller should always provide himself with a mosquito net to place over his cot; otherwise, sleep is wellnigh impossible on certain parts of the river. As the climate is so mild, bedding consists merely of two sheets.

The fuel supply on the lower river service is wood, cut by natives and piled along the banks at convenient intervals. Every boat carries a crew of cargo handlers, who bring the wood down the bank and across the gangplank on their shoulders, piling it up close to the boilers and fire box.

The interest attracted by one's fellow passengers is varied. There may be a bevy of convent bred girls accompanied by two or three sober faced sisters in their demure uniform of white and black; sombre robed priests with their flat crowned hats and well nourished bodies amble about the boat; young Colombian gallants, generously supplied with necktie and gorgeously arrayed of hosiery, twirl their inevitable mustaches with abandon. French, Spanish, and English are spoken on all sides, as well as a good deal of German, and the traveller who has even the rudiments of these languages at his command, can find plenty of opportunities to practice them.

We will suppose that the object of the expedition is to prospect one of the areas of dredgeable ground (of which, omitting discussion of gold content, there appear to be many) lying adjacent to one of the tributaries of the upper Magdalena. The most promising of these tributaries appear to flow east from the Cordillera Central toward the Magdalena. As most of them have small villages at their junction with the Magdalena, the method of procedure is about the same for any of them. The steamer will disembark you at any hour of the day or night that you happen to arrive, and the *cargadores* will unload your personal effects and your equipment, including your drill (in our case an Empire.)

You will then hunt up the principal merchant of the village (if you are wise, you will have a letter to him) and make arrangements to have yourself supplied with canoes and *vogas* (native boat handlers) to transport your expedition up the river. Before making the trip with all hands and the cook, however, you will of course want to make a preliminary voyage to inspect the deposit generally and to pick out a camp site. This being done on the first day, or the first two or three days, if you have to go far up the river, you will, if you are wise, make a binding agreement with the aforesaid local dignitary as to just how much he is going to charge you for men, canoes, and whatever supplies he may furnish you with. Then you are prepared to start up river and make your camp.

The native Colombian canoe is a very convenient institution. It is a log dugout, tapering at both ends, and varying in diameter, or rather, width, from eighteen inches to three feet. It is propelled by from one to three natives (and, in the case of the larger canoes, or *champanas*, many more), with the use of long steel-shod poles, by means of which, keeping close to the banks, they propel the boat forward against the current alternately, the steering being done by one man with a paddle seated in the stern. When on account of creepers it becomes impossible to get close enough to the bank to use poles conveniently, or the flow of the current becomes too strong, the bow men drop their poles in the boat, and pick up paddles, crossing to the other side of the river and resume their poling.

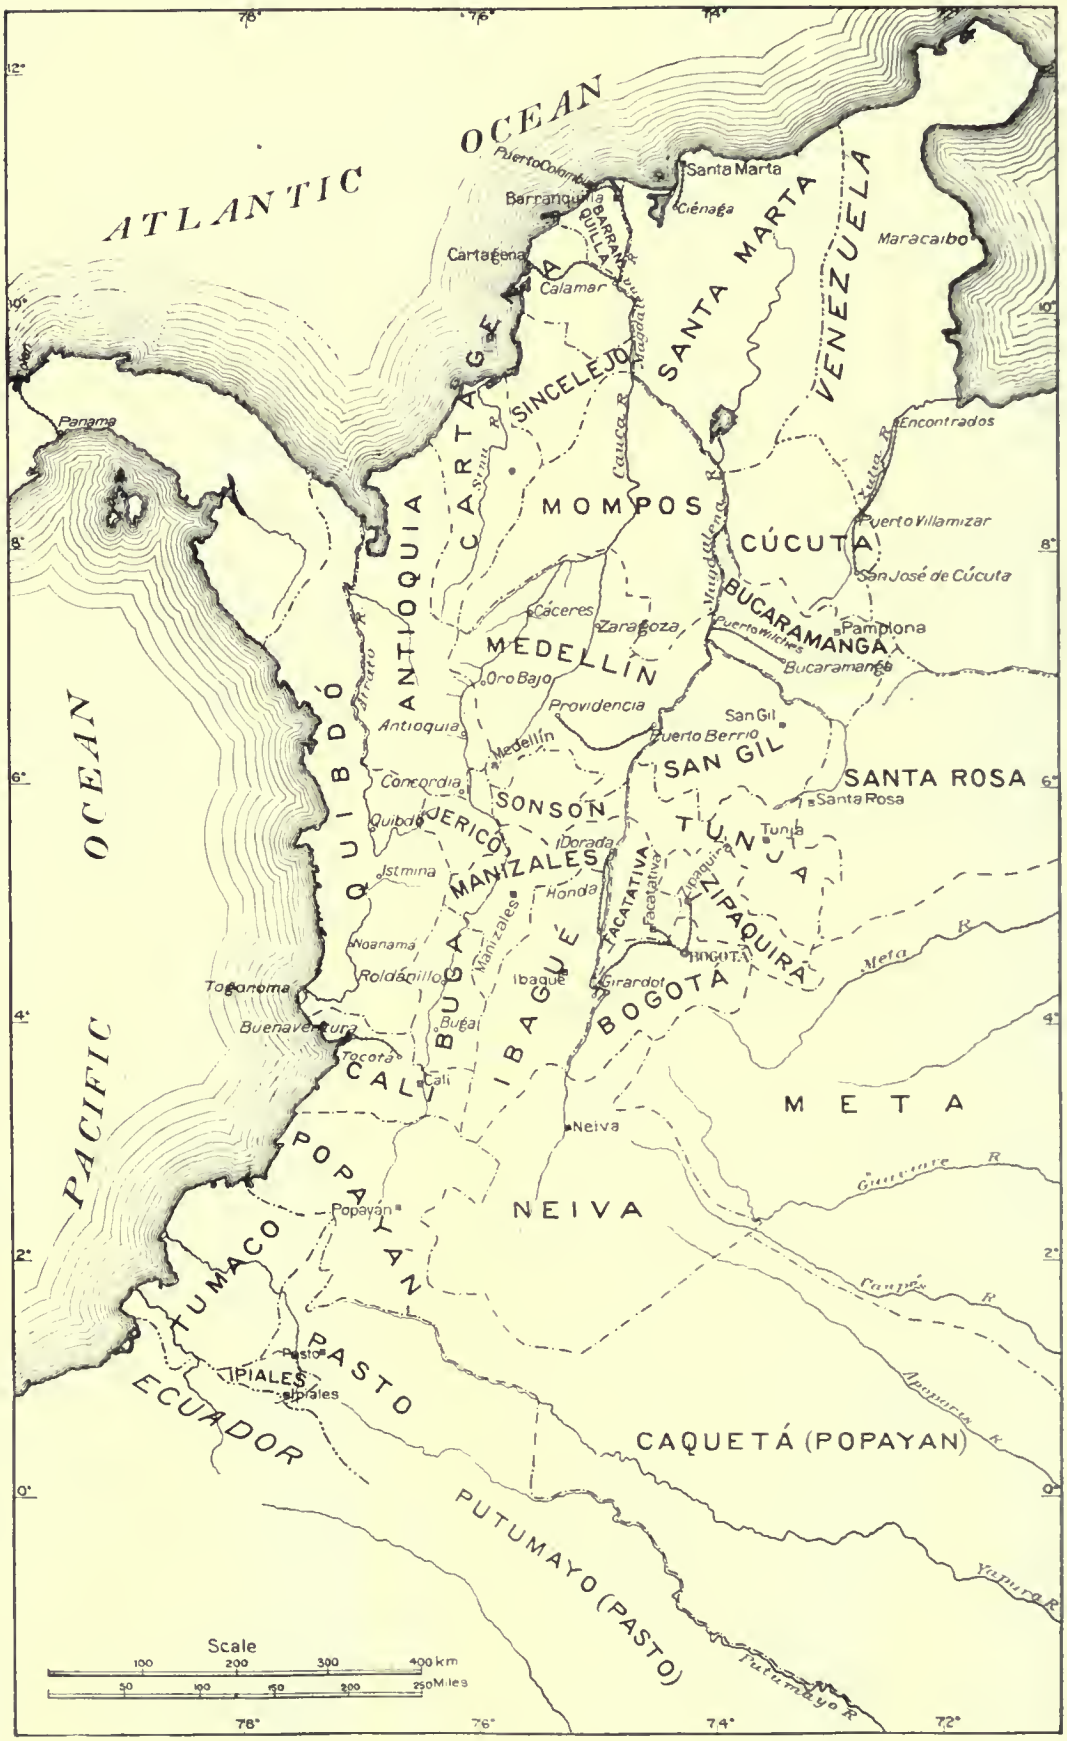
All cargo is placed well down in the boat, to prevent capsizing (for these craft are, to say the least, cranky), and a surprising amount, for such frail craft, may be so stowed. A dugout canoe about 25 ft. long and $2\frac{1}{2}$ ft. wide will easily hold a ton of freight as well as passengers, and will require three men to work it. The result is that camp supplies and a hand drill can be carried readily up all but the most torrential streams. After mule back trips through the Andes the Colombian canoe on the rivers is a welcome, if somewhat torrid, method of transportation.

Selecting a Camp Site

Arrived at the locality where you desire to start operations, you are confronted with the problem of where to place your camp. You will naturally desire to be in the shade of trees; yet if you get too far back from the river you will be bothered with vermin, ants, and insects of all kinds. The closer down to the river, the easier to get your water for all camp purposes; and yet, with a heavy rainstorm and a ten-foot raise in the river your whole camp may be flooded out. So it is merely a question of judgment and experience, after all. But it is while clearing a space for your camp, and stirring up a lot of aged leaf mold and rotted tropical wood, as well as cutting a way through the jungle for your drill, that you will begin to realize what a well populated country Colombia is—from the insect standpoint. Ants, small flies with a poisonous bite much larger than them-

selves (*aliens*), and mosquitoes, will hail your coming with joy and hasten to greet you. To all of this you will in time become accustomed, however.

Your camp once established and made livable, and your drill assembled for work, the first question to which you must turn your mind is labor. Being several miles away from the main highway of the Magdalena, it might seem that your difficulties would be increased; and, in a way, they are, as far as getting together a sufficient working force is concerned. On the other hand, this difficulty is more than compensated by the quality of the men that you do get. The cargo handlers that you will get from the little villages along the Magdalena are not accustomed to the steady grind of daily labor, and are mostly too lazy to make good workmen. In the little clearings in the interior, and among the ivory nut gatherers, who are mostly Antioquanians, you will find a hardier stock, much more trustworthy and teachable, and above the average South American laborer in intelligence. Furthermore, although all of them seem to be infected with malaria (a condition in which, if you are not unsparing in dosing yourself with quinine, the mosquitoes will soon put you yourself) it only attacks them intermittently, and is soon over with. A good supply of quinine and of purgatives is essential if you wish to keep them in good condition. Of course, in a place of this kind, remote from villages, it will be necessary for you to run a special camp for the purpose of boarding them.



MAP OF COLOMBIA.

Food and Supplies

Bananas and yucca are abundant in the little clearings up and down the river from you, and form the staple articles of diet. *Panela* (caked crude brown sugar), beans, rice, and tobacco you will have to bring up from the river. A meat ration, though rather costly, will help to keep your men with you; something of great advantage after you get them broken into the work. A camp of the sort described will cost about 30c. per day per man; and in addition, in this part of the country, wages will be 40 to 50c. gold per day, making the total cost for labor about 75 to 80c. per man.

Horses are hard to obtain in a country where all freighting is done by canoe; and furthermore they are absolutely unused to any kind of traction when you do get them, as they are used solely for packing. The result is that you will probably have to use man power for turning your drill. In deep holes this necessitates 8 men on the sweeps, whom you can interchange at intervals during the day with the 4 men on top of the drill, thus rendering the work a little easier and expediting it not a little. The Antioquanian is a fair mechanic, for a native, and soon learns just what you want him to do. He is usually cheerful and when he is not joking with his neighbor, tries to do the right thing. In handling this, as all labor in South America, one should continually remember that he is dealing with the intellects of children, and not expect too much. However, the engineer is not continually exasperated with the inefficiency and helplessness, as well as incorrigible laziness, of these people as he is, say, with the cheaper Peruvian labor of the Andes.

Cutting Trails

The country itself, at first sight, seems to be an impenetrable jungle. On commencing clearing operations, however, and cutting a way through for the drill, it does not look so formidable, and it is surprising how much ground can be cleared in a short time by a few natives, armed with their inevitable *machetes*. This latter tool, and the skill and speed with which they use it for every purpose imaginable, from building thatched huts to digging holes, is something of a revelation to one who has never seen it.

The larger trees are not too thick to interfere with the work, and their shade is often very grateful during the operation of drilling. For the most part their roots are all on top of the ground, which facilitates clearing immensely. Their interlocking branches are used as roads by the monkeys, who usually become very much interested in operations. Whole swarms of them will hang around the drill, scolding and roaring the while the men are working, and their actions are often very amusing.

These monkeys, especially the smaller ones (*micos*) are regarded among the natives as quite a delicacy, but naturally do not greatly appeal to a student of evolution. On the other hand, parrots and guacomayos are abundant and tough wild turkeys may be had if one cares to make the effort of hunting them—an effort which is well repaid in the enrichment of the bill of fare, and forms a welcome diversion for a few hours from the exacting work of careful drilling.

From a geological standpoint, this country is very simple. The underlying country rock is for the most part a very fine grained sandstone with limited areas of hard limestone which occasionally crops out in the rolling hills which divide the different river systems from one another in anticlinal folding. The meandering rivers turn forward and backward from one range of hills to another. There are few large boulders of country rock in the gravel, and a considerable proportion of soft sand and clay, especially in the lower reaches near the Magdalena. The gravel itself is rather easily worked from the dredging standpoint, being small and loose, with a very small proportion of clay except, as stated, within a mile or two of the main river.

Native Stream Testing

In many of these streams there is a small amount of flood gold on the surface which is yearly worked out by the natives with *bateas* whereupon another crop is deposited by the next season's floods. This gives rise to the idea that the gravel itself is rich enough for extensive working on a large mechanical scale; but this impression is apt to be misleading. Only careful prospecting will show whether the ground is worth while, and no attention should be paid to surface showings.

In considering operation in this country, the freight rates present a serious problem. Aside from the rehandling charges at Puerto Colombia and Barranquilla, and the excess rate of from 100 to 200% that is charged by the New York steamers and the Colombian railway for all pieces of machinery of great weight, there is a similar excess rate all the way up the Magdalena. If the property be above La Dorada, extra rehandling and excess on the railway will be charged. Aside from this, in case of operations on the upper reaches of any of these rivers, lighters and launches would have to be used. Present methods are expensive for operations on a large scale.

Proceeding up the Magdalena to La Dorada, the end of the lower river steamer line, the passenger transfers to the Ferrocarril de La Dorada, which runs almost parallel with the river to Ambalema, the principal towns on its line being Honda and Mariquita. These latter towns are very ancient, dating from colonial days, and derive most of their support from being the shipping points from the Magdalena over the Manizales trail to the Cauca River valley. A great deal of freight goes over this trail every day, the chief freight carriers, besides mules, horses, and burros, being steers. Looking back on the trail from the hills above Mariquita, the traveler sees an apparently never ending procession of these oxen, heavily laden with German packing cases, toiling patiently up the hill, urged on continually by the sharp cries of the drivers, but moving painfully slow.

An aerial tramway is now being constructed by an English company from Mariquita to Manizales, a distance of some 90 miles, which will upon its completion greatly expedite the handling of freight. The towers are of steel on concrete base, and will presumably be operated on the same system as the Bleichert.

Geology of the Country

A sharp change in the geological character of the country may be noticed immediately after leaving La Dorada. This change is probably responsible for the existence of the railway, as it renders the Magdalena more difficult of navigation. Flows of lava, dikes, and sills of porphyry (chiefly andesite and basalt), and batholiths of granite and diorite make sharp ridges where formerly there were low rolling hills. Also, the character of the vegetation changes accordingly. Where formerly there was nothing but thick jungle growth, now long plains of luxuriant grass are visible on all sides, and many little cultivated ranchos appear.

To the west of Mariquita rise the lower slopes of the Cordillera Central, which have been so heavily eroded that there is almost nothing left on top of the granodiorite which seems to be the chief underlying plutonic of the country. In this range, at Bocaneme, Fresno, and numerous other small settlements, there are small mines, chiefly of silver, with rather base ore. Although not what would be called a free gold country, there are nevertheless some placer mines, notably along the Rio Sucio, which empties into the Magdalena at Honda. In this connection one thing is apparent to the hydraulic miner. The granitic bedrock is so far decomposed underneath the gravel that if there is any heavy bedrock gold at all, it is necessary to wash from 5 to 12 ft. of absolutely worthless soft granite through the boxes in order to get it. This is a condition which I believe obtains only in tropical countries subject to violent atmospheric action and weathering.

Labor conditions here are even better from the operators' standpoint than they are farther down the river. The regular rate of pay is from 50 to 60c. per day, without board. And in this area I found the best, most efficient and industrious workers that I have yet seen in South America. How long this state of affairs will continue after the ropeways have opened up the country, and labor is more in demand I do not know; but at present a chance to work and make a little money seems to make a strong appeal to these people, and they work well.

While stopping at Mariquita, a party of young men from the Canal was encountered, who were engaged in preparing a 52-ton steam-shovel for a trip into the interior, where it was to be used for placer mining. What the prospects may have been for successful operation were of course unknown; but this machine, bought second-hand on the Zone for $4000 or $5000, by the time it was set up and ready to move into the interior, cost them two to three times that much. This is mentioned as corroborative evidence that early-day methods of the buccaneers of obtaining money have been improved by modern enterprise.

Leaving Mariquita, one takes the railroad again to Beltran or Ambalema, where connection is made with the smaller steamers of the upper river service on the Magdalena. In 24 hours one arrives at Girardot, a thriving little town of about 20,000 inhabitants, and the port of entry for Bogota, a day's journey away by railroad. A great deal of trading in hides and coffee is done from this point.

Here again the geological and physical characteristics of the country change. On the east, the mountains rise sharply for several thousand feet; but on the west side of the river is a wide, rolling plain, which grows more dry and arid as it extends from the Magdalena. Vegetation grows less and less, till, over on the tributaries of the Soldano river, one sees nothing but the parched dry grass of certain parts of the western United States. The country rock has changed from porphyry and granite to a very hard, indurated sandstone which is close to the surface and crops out in many spots, at times intermingled with a fresh water conglomerate.

Suddenly, however, you come to the sharp depression of the Soldano and its tributaries the Cucuana and the Ortega, which flow down from the now rolling foothills of the Cordillera Central. On either side of the former river the brown, dry hills give place to broad and verdant flats, covered with tropical vegetation. These flats have been worked by the Indians for hundreds of years with *bateas;* and more especially the higher ones of bench gravel, which run back into the hills. The gravel here appears more shallow than that lower down the Magdalena, however. It is also a little heavier.

Character of the Labor

The labor available is abundant, cheap, and of exasperatingly poor quality. Wages are 50 to 60c. per day. The natives are apparently less accustomed to hard work than the Antioquanians, and not anxious to become too accustomed. They are chiefly agricultural in their habits, raising a great deal of corn, bananas, and coffee. The principal means of transportation in getting their products to the market is by means of *balsas*, or light rafts, which they load heavily and manipulate by paddles down the river. Surprisingly large loads are handled this way; I having taken a complete Empire drill (previously packed in on muleback), two tents and a complete camp outfit, as well as five men, down the Soldano and Magdalena to Girardot on a raft which was far from being the largest procurable. It requires a fairly skilled pilot to handle one of these craft, as the river is narrow and swift in many places, as well as having many riffles. Several times on our trip down we passed whole groups of natives on the bank, engaged in repairing a wrecked *balsa* which had bumped against a point of rock and collapsed.

As yet, it is hard to make any definite statement as to the mining possibilities of this region, especially with regard to alluvial ground. As a whole, there are too

many silver and silver-lead mines in the region to characterize the country as a free gold country, as may be done in the portion farther west, just over the Cordillera Central, and also still farther over, in the valley of the Atrato. On the other hand, the proportion of galena and copper sulphides is not high enough to characterize the country as base, the greater portion of the silver coming from stephanite and pyrargyrite ores, containing a considerable proportion of gold. Also, as more concrete evidence, there are, and have been for many centuries, alluvial mines in operation, with varying success. For this reason, until the country has been more thoroughly examined, and possibly developed, any statements of a wide general nature as to its possibilities should be avoided as far as possible.

With a light hand drill prospecting operations can be carried on under what are, for the tropics, rather favorable conditions, both with regard to labor and comparative freedom from fever. The gravel is for the most part light, the jungle growth is in no way a serious obstacle, and communication between one area and another is greatly facilitated by the abundance of waterways.

However, conditions for operation on a scale of any magnitude, especially from the standpoint of freight rates and rehandling as well as transportation up the shallower rivers, are such as to make it especially incumbent upon prospective operators to be sure of their ground first by thorough preliminary examination. The presence of a considerable quantity of fine gold near the surface of the gravel, which feathers out to nothing at depth, has been responsible for the wasting of a good deal of valuable time and money in tropical countries, and doubtless will continue to be. It should always be borne in mind that countries subject to sudden and extensive floods are deceptive in this regard. On the other hand, where the ground has been systematically and properly drilled by competent engineers, there is not much danger. Costs, even though excessive, can be figured beforehand; and recent figures on the output of the companies mentioned at the beginning of this article will give an idea as to their possibilities.

Something of the possibilities of placer mining in Colombia is indicated by the success of the Pato dredge which, after much delay, has now begun to make regular and satisfactory returns. The San Francisco property adjoining has been prospected and a second dredge is about to built on it.

FLINT PEBBLES worth $320,000 were imported into the United States from Denmark and France in 1913. In these countries the flint occurs as irregular nodules in chalk cliffs of the coasts. They are used for pottery work and in tube-mills. The supply is now interrupted on account of the war. Flints, which would have to be artificially rounded, occur near Austin, Texas; also rounded quartz pebbles in the valleys of many rivers draining regions of crystalline rock—for example, the Potomac near Washington, D. C.

Origin of the Diamond

Before the South African Association for the Advancement of Science, W. Johnson read a thoughtful paper on the origin and formation of the diamond, a subject that has often been discussed in the past, but one possessed of so much scientific interest that further examination of the problem is always worth recording. Mr. Johnson is reported in the *South African Mining Journal* as follows:

"My view of the matter is that graphite probably took no part in the formation of the diamonds at all, but that they were formed from another carbonaceous material before it had reached the stage of graphite. The factors determining whether a certain carbonaceous material should undergo a change to graphite or to diamond were a high pressure and a certain temperature, probably not very high, not higher, perhaps, than a low red heat. This view quite accords with the opinion expressed by Sir William Crookes years ago when he declared that the difference between graphite and diamond was probably a difference of pressure at the time of formation; that is to say, that other conditions being favorable certain carbonaceous substances undergoing metamorphosis might, if the pressure were sufficiently high, be transformed into diamond, whereas at a lower pressure they would be changed only into graphite. Such a view dispenses with a high temperature, and all the difficulties that attend the theory of the high-temperature formation of the diamond. It also accords with the fact that when the graphite that is found in the blue ground is examined it is seen to have the character of natural graphite. It still contains a small proportion of oxide of iron and silica like natural graphite, and reacts with strong sulphuric acid just as natural graphite does. * * * Regarding the different character of the diamonds, not only in different pipes and dikes, but also in different parts of one and the same pipe, the geologists up to and including Mr. Wagner very fully, and properly, have called special attention to it, and yet it does not seem to occur to them that it would be a very difficult matter to reconcile the fact that there are in some pipes, for instance, four or five different columns of kimberlite, each with different diamonds, with the supposition that all those columns came from a presumably white hot common centre of molten rock. Such differences are surely more likely to arise under conditions of igneous metamorphism than if all this vast rock magma in a white hot molten condition, and extending over hundreds of miles, were the proximate source of the materials filling the pipes."

MINERAL PRODUCTION of Maryland in 1913 was valued at $11,292,723, compared with $10,851,671 in 1912. Coal mining accounts for over 50%; clay products, 1.7%; and quarries, 9% of the total.

COKE OVENS in the state of New York number 555, supplied by coal from Pennsylvania.

Gold Mining in Mongolia

A curious feature about the gold deposits of China is that they seem to occur mostly along her northern border. Gold occurs in limited amounts in many places throughout the Empire, but the most widespread and rich deposits occur along the Amur river, and on the west of it in Mongolia. The workings along the Amur river are very well known, as many English and American engineers have visited them and described the deposits and the methods of work pursued. One of the best of these descriptions is that by Chester W. Purington, which appeared in *The Mining Magazine*, January 1911.

An important district of which almost nothing is known is in north central Mongolia. Throughout this area there is a certain amount of native work, but the only large individual enterprise is that of the Mongolyor company. This is a Russian company which was organized by Baron von Grote, which has secured from the Chinese government a concession to prospect for a mine all the gold found in the two *aimaks*, or districts, of Tuschetu-khan and Tsetsen-khan. The directing of the work in Mongolia is now in the hands of I. V. Pokrovski. Some of the early development work was done by American engineers. The original proposal to use dredges and similar large scale work has proved impracticable and it is now being carried out along the lines familiar to Americans of an earlier generation. The log cabins of the native workmen are indeed strongly reminiscent of the old mining districts in the West. A lieutenant in the British army, C. G. Binsteed, has recently visited the district and the following is taken from his account of the work of the Company, published in the *Far Eastern Review*.

"The Company now works the following fields in the Iro River basin: Iro, Tologoika, Mogoi, Harganati, Narin-Harganati, Yalbik, Ulentoi, and Nikho, while outside the Iro basin work is carried on in the valleys of the Kudara, a tributary of the Chikoi in Mongolia, Tereltzi, tributary to the upper Kerulen, and Hera Gol at Tzo Modo. Prospecting, which is chiefly carried on during the winter, is being further extended in the Kerulen and Onon basins and southwest of Urga. Mr. Pokrovski himself hopes next year to reconnoitre the Onon and Uldza areas. The administration headquarters and head offices of the Company have just been moved to the Iro goldfield. These are connected by telephone with the other fields in the Iro basin, but the projected plan for a telephone line to Urga has not yet been realized. A map of the area from Kiakhta to Urga has already been partly made and is being completed. This survey will later be extended to the new areas in which it is hoped that gold will be found. A postal service connects the Iro headquarters with Urga. All the gold obtained by the Company is sent *via* Kiakhta and Russia to Belgian and French firms. The Russian government is a somewhat unsatisfactory purchaser for the reason that it refuses to pay on delivery for the total amount received; only consenting to pay for the nearest round number quantity in weight below what is actually delivered. As gold is very expensive compared to its weight, it often happens that large sums of money are left owing to the vendor until the next consignment of gold arrives. The Belgian and French firms, on the other hand, pay at once the exact price, and even at a somewhat higher rate than the Russian government, for the total amount delivered at each consignment.

"The Mongolyor company uses three methods for obtaining its gold. These are: (1) work by the Company

PART OF MONGOLIA.

itself by means of laborers hired by the day; (2) the lease of whole areas to capitalized organizations, who find all the necessary capital for exploitation, pay no rent, but are bound to sell all gold obtained to the Mongolyor company at rates from 24 to 27 rubles per Chinese liang of weight ($10 to $12.50 per troy ounce); (3) lease of small areas to minor combinations of laborers who are provided by the Company with the necessary equipment and are bound to sell all gold to it for about 24 rubles per liang ($10 per ounce). To its own day laborers the Company pays a daily wage of 1 ruble (51½c.) to Russians, and 0.80 rubles (41¼c.) to Chinese. The Company is now instituting more modern methods with machinery and horse traction for the earth carts. Inspectors are appointed to prevent any stealing of gold by day laborers or by the minor lessees of areas. Sealed dredges are also used for the purpose. All workers on the mines pay to the Mongol government

a tax of 1 ruble per head per month for the right to work in the fields, in exchange for which they receive a form of passport.

"On the whole, Chinese still predominate somewhat in the goldfields, though large numbers have departed recently, partly owing to the disabilities imposed upon them by the Mongol government, partly because of new regulations by the Company, whereby, instead of receiving a modicum of food during the winter, they are now left to find a livelihood for themselves, and partly owing to the great recrudescence of brigandage in the neighborhood. The latter circumstance accounts for the departure of very large numbers not only of Chinese but also of Russian workers from the goldfields. This summer brigandage became so bad that about 100 Russian soldiers from Kiakhta were sent into the area and were distributed from the Khangai range northwest of Kornakovka eastward to the Iro goldfield. The increase of brigandage is itself chiefly due to the fact that now numbers of Chinese are left without means of livelihood during the winter."

The following figures give the approximate yearly find of gold in the Mongolyor fields:

1901-1908	average	$120,000
1908-1909	"	773,000
1910	"	1,306,300
1911	"	1,306,300

The yearly profits of the Company were as follows:

1907-1908	$8,000
1908-1909	88,000
1910	192,000
1911	175,000

Auto-Reduction in the Precipitation of Metallic Gold

By VICTOR LENHER

*In the various studies which have been made on the precipitation of gold from solution, attention has been directed for the most part to the action of various reducing agents on gold solutions. The general chemical inactivity of gold enables us to deposit the metal in elementary form by most of the metals, the metallic sulphides, ferrous salts, various organic compounds, and, in fact, in the ordinary sense of the word, gold compounds are readily reduced to metal by the mildest of reducing agents. On the other hand, very little attention has been directed to the precipitation of gold in the metallic condition by oxidizing agents. A few isolated cases of the auto-reduction of gold from its compounds by certain oxidizing agents have been recorded, but the general principle of the auto-reduction of gold compounds has not received systematic study from the standpoint of the deposition of gold.

It has been known for a long time that hydrogen peroxide, when brought in contact with oxide of gold or oxide of silver, will reduce either of these metallic oxides to metal; water and oxygen being formed simultaneously.

$$Au_2O_3 + 3H_2O_2 = 2Au + 3H_2O + 3O_2.$$
$$Ag_2O + H_2O_2 = 2Ag + H_2O + O_2$$

In a similar manner, gold solutions in contact with hydrogen peroxide yield metallic gold, oxygen being evolved at the same time. This reaction of hydrogen peroxide with gold compounds takes place in either acid or alkaline solution. Sodium peroxide and sodium perborate precipitate metallic gold immediately from gold solutions. Barium peroxide and calcium peroxide act toward gold solutions in exactly the same way, precipitating metallic gold at once. These compounds are perhaps closely related to hydrogen peroxide and, as a consequence, act similarly toward gold solutions. Osmium tetroxide, or the so-called osmic acid (OsO_4), when dissolved in water will not reduce gold solutions, but when the free acid is neutralized, or when the solution is made alkaline with sodium hydroxide, sodium carbonate, or calcium carbonate, metallic gold is precipitated. The higher oxides of nickel and cobalt, prepared by the action of an alkaline hypobromite on solutions of nickel and cobalt chloride, when brought in contact with a solution of gold which has been rendered alkaline, precipitate metallic gold.

Lead peroxide, as well as red lead, precipitates metallic gold from either neutral or alkaline gold solutions. Ceric oxide, prepared in the hydrated form by rendering ceric chloride alkaline, precipitates metallic gold at once from a gold solution which has been rendered alkaline. The compounds of manganese present interesting deportment along this same general line of auto-reduction. Manganese dioxide, prepared by the action of bromine on a manganese acetate solution, precipitates gold from its solution either under slightly acid, neutral, or alkaline conditions. Potassium permanganate, on being allowed to stand for some time with auric chloride, causes metallic gold to be precipitated along with manganese dioxide. The minerals pyrolusite, wad, braunite, and manganite, when brought in contact with a gold solution, which is either acid, alkaline, or neutral, slowly cause gold to deposit.

Recently Brokaw[1] has shown that manganese salts, when made alkaline, or even manganese carbonate will precipitate gold from solution. The direction of the reaction between manganous salts and gold chloride is considered by Brokaw to be largely due to hydrolysis of gold chloride solutions, although the equations, as given, show that gold chloride and manganous salts react in neutral solution to form manganese dioxide and metallic gold. All of the reactions recorded by Brokaw have been

*From the *Jour.* Amer. Chem. Society.

[1] *Jour. Eng. Ind. Chem.*, 5, 560 (1913).

studied and corroborated. That manganese can be of considerable importance in the deposition of gold is unquestionably true, and its function may be that which Brokaw has suggested; but, in addition, manganese may play the rôle of a reducing agent, acting solely through auto-reduction.

Auric compounds, as is well known, are easily reduced to metallic gold, and, hence, can be considered as oxidizing agents and can, obviously, oxidize manganous hydroxide to manganese dioxide. It can therefore be considered that the mutual precipitation of gold and manganese dioxide by calcite, as cited by Brokaw, is simply the neutralization of the excess of acid, whereupon the oxidation of the manganese by the gold solution results in the precipitation of both manganese dioxide and metallic gold.

That this is the direction of the reaction is evidenced by the duplication of the phenomenon by replacing manganese salts with cerium compounds. Cerous hydroxide precipitates metallic gold in alkaline solution; the cerium being at the same time oxidized to cerium dioxide. Similarly, when a piece of calcite is introduced into a solution of cerium chloride and gold chloride, as the free acid is neutralized by the calcium carbonate a deposit of cerium dioxide containing metallic gold begins to form on the calcite.

The presence of gold in the manganese deposits, which has been studied by Emmons,[2] may be due to the fact that manganese is a significant agent in the superficial transportation of gold; but such is by no means necessarily the case. Two distinctly different kinds of reactions may be going on. In one case a chloride solution, containing free acid, on coming in contact with an oxidized manganese deposit will produce free chlorine, or its equivalent. This chlorine solution can then dissolve gold and cause the production of a gold-bearing manganese solution, which, so long as it contains considerable free acid, is quite permanent; but, when it comes in contact with any neutralizing agency, for example, limestone, metallic gold and manganese dioxide would be at once precipitated. This accords with experiments which have been reproduced in the laboratory, and which do not, as indicated by Emmons, require such a reducing agent as ferrous sulphate or other reducing agents as indicated by Wells,[3] to produce a precipitate. On the other hand, the gold present in the manganese deposits adjacent to other gold deposits may be due wholly to the fact that gold solutions in contact with manganese dioxide yield metallic gold, by virtue of the principle of auto-reduction shown by other peroxides with gold solutions. The auto-reduction of gold solutions to metallic gold has apparently, thus far, not been considered as an important geological factor in the secondary deposition of gold, but it is doubtless possible that in many instances one can conceive of the oxygen of the air as being the real agent which causes the gold to be reduced in presence of a manganese or similar compound which acts as a catalytic agent.

Estimating Arsenic in Ores

By BASIL G. DUNSTAN

This may be termed a general method, and is as follows: Weigh out from 1 to 5 gm. of ore, add 10 c.c. of tartaric acid solution and 15 c.c. strong nitric acid, cover the beaker and heat until the ore is decomposed, add 20 c.c. 1:1 sulphuric acid, cover and boil until all nitric acid is driven off. This is evidenced by a sudden rush of red fume toward the finish. When this occurs heat for half a minute longer. No charring of the tartaric acid should take place. Allow to cool, and dilute to about 50 c.c. with warm water, cool, filter, and wash the precipitate twice with warm water.

To the filtrate add about half a gram of sodium sulphite, and boil down to 50 c.c.; this completely reduces the arsenic and expels all sulphur dioxide.

To the cold solution in the flask add 100 c.c. strong hydrochloric acid, and saturate with sulphuretted hydrogen, usually about 5 to 10 minutes. Filter off the precipitated sulphides and wash twice with cold 1:1 hydrochloric acid, and twice with cold water.

Wash the precipitated sulphides off the filter paper into a small beaker, decanting back through the filter any excess of water. Dissolve the portion adhering to the filter with the mixture of one part strong ammonia and one part hydrogen peroxide, allowing it to run through into the beaker containing the rest of the precipitate. Boil the solution to effect complete solution and oxidation of the arsenious sulphide, filter if necessary, and boil down to 10 to 20 c.c. Cool, and add 10 c.c. strong ammonia. Cool and add gradually 5 to 10 c.c. magnesia mixture, stirring continually for about 5 minutes; and allow to stand over night.

The precipitated ammonium magnesium arsenate is filtered off through a previously ignited and weighed alundum filtering crucible, and washed three times with ammonia water (3 parts water to 1 part ammonia). Dry in water oven and ignite over the blowpipe for 10 minutes, cool and weigh as $Mg_2As_2O_7$.

The tartaric acid solution is made by dissolving 400 gm. tartaric acid in 400 c.c. water, and adding 400 c.c. strong nitric acid.

Magnesia mixture: take 110 gm. magnesium chloride and 140 gm. ammonium chloride and dissolve in 1300 c.c. water.—*The Chemist Analyst.*

UNDEVELOPED DEPOSITS of barytes occur in Mariposa county, California; Clark, Elko, Mineral, and Nye counties, Nevada; Blaine county, Idaho; and in Alaska. In 1913 the output of the United States was 45,298 tons worth $3.45 per ton. Imports were 35,840 tons worth $1.71 per ton. The European war has cut off foreign supplies, which should direct attention to domestic sources of this mineral.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply to E. T. Mellor's Discussion

I was much interested to learn that E. T. Mellor had commenced his geological survey of the Witwatersrand district with inclinations toward the infiltration theory of the origin of the gold in the banket; but, that after four years' study he considers his investigations have not furnished any evidence in favor of that view, and that he claims to have met with much evidence in favor of a placer origin, in addition to that already advanced by advocates of this latter theory.

This is the opposite of what occurred in my own case. I was at first impressed with the seeming simplicity of the placer theory; but, my study of the deposits during my underground work in the mines and my comparison of them with deposits with which I was familiar in other parts of the world soon led me to abandon this theory as untenable, and after more than ten years' study, I consider that these auriferous conglomerates are merely an abnormal type of lode deposit.

Being acquainted with the silver-lead deposits of Przibram in Bohemia, I am able to appreciate Posepny's words in regard to them, and as I think these also apply in a great measure to the Rand, I quoted them in my paper; and it may not be amiss to do so again now. Posepny remarked,[1] "If we imagine ourselves standing in the deep region in front of the profile of an ore lode like the Adalbert at Przibram, for instance, 1110 m. (3600 ft.) below the surface and 564 m. (1850 ft.) below sea-level, we perceive a fissure-space of diseission, filled with symmetric mineral crusts, chiefly argentiferous lead sulphide. Remembering that this filling has been stoped continuously to the surface we can find no other satisfactory explanation than the hypothesis that it was brought up from still greater depths, and, in view of the comparative insolubility and the large quantity of the metallic sulphide here accumulated, it must have been deposited from perpetually renewed, and, therefore, from *ascending*, mineral solutions. Whoever has had opportunity to study an ore lode in the deep regions can conceive no other explanation. The miners themselves have always held this opinion, they have all been *ascensionists*."

I arrived at my conclusions as to the origin of the gold in the bankets by inductive reasoning from my study and observations, underground, of the lodes themselves. To the geologist, doing his work almost entirely above ground, the placer theory is doubtless attractive; but, to the mining engineer studying these deposits in the mines the lode theory certainly seems the more rational one.

As stated in my paper, De Launay emphasized the fact that in a placer deposit a fall in the gold contents was to be expected as distance was gained from the former shore line; and, T. A. Rickard in his discussion pointed out that in the case of the Nome placer deposit the total distance, at right angles to the old shore line, over which the gold occurred, was at most only 100 ft. It will need a vast amount of ingenuity on the part of the placer theorist to reconcile merely this one fact with the wonderful persistence in depth of the mineralization of the banket.

I quite agree with Mr. Mellor that there has been considerable local re-distribution of the gold contents of the reefs. I pointed out that the zone of secondary enrichment extended beyond the bottom of the oxidized zone. Such secondary enrichment is a common feature of lodes.

As regards the influence of dikes, it seems to me to be no argument against the important part that they have played, that there are many which do not appear to be associated with specially rich portions of the banket; nor does it detract from the important significance of the fact that the big longitudinal, or strike, dikes contain gold.

I shall await with great interest the arguments that Mr. Mellor shortly intends to advance in favor of the placer theory of the origin of the gold.

C. B. Horwood.

Application of Flotation to Gold Ores

The Editor:

Sir—I have just seen the reference to this subject in your issue of June 27. As a matter of record, your readers may be interested to know that the 'Elmore' flotation process has been at work on this mine for about 12 or 13 years. Both the original process of Messrs. Elmore and their later improvement, the vacuum process, have given highly satisfactory results. The vacuum process has been in continuous operation for a number of years and is still being used. The average value of the ore treated is about: copper, 1 to 1.25%; gold, 1.5 to 2 dwt. per ton of 2240 lb.; silver, 0.5 to 0.75 oz. per ton of 2240 lb. It will be recognized what excellent

work is being done by the Elmore process when I say that profits are made on treating ore of the above grade, after paying mining, development, milling, road transport of five miles, rail transport of about 100 miles to smelter, smelting charges, debenture interest, administration charges, London office, and all other expenses. There is milled about 80 tons per day of 24 hours.

The working costs of the Elmore process are low because coarse crushing (about 20 mesh), compared to the 80 to 100 mesh required by other flotation processes, is permissible, and the Elmore concentrate being granular and coarse, does not require any filter press or other artificial means of drying, and is not liable to be carried into the furnace flues in subsequent smelting. This is certainly the earliest application of flotation concentration to auriferous and argentiferous copper ores, and antedates by several years those mentioned in your note.

Dolgelley, Wales, July 17. JOHN BEVAN.

Juga Estimates

The Editor:

Sir—I notice in your issue of May 30 certain comments by your London correspondent concerning the estimates of engineers connected with the Juga (Nigeria) Tin and Power Co., Ltd., and a closing remark that they may have some explanation or answer to give in regard to the discrepaneies between the reports.

In November 1912 I furnished the Company with a report giving the total tin content of the areas at one-fifth of that estimated by their consulting engineer, C. G. Lush, but they ignored the discrepaney. In faet, they considered my report pessimistic and relieved me of the management, stating at the time that they considered the areas required an expert in gravel pumping, and that they could then secure one. They have not stated the result of that expert's term of office, nor have they informed the shareholders that the sampler on whose work the greater part of my estimate is founded, had offered to return to Nigeria at his own expense and re-sample the mine provided the Company sent an independent engineer to view the work. I reminded the chairman of this fact two days before the general meeting, but still it was left unmentioned, and they did not avail themselves of it. Neither did they pursue an intention of twelve months earlier sending one of their own board, himself a mining engineer, to examine the mine. In expectation of this latter visit, I have refrained from making any comment. The differenee between the reports of the consulting engineer and myself was ample justification for the board to call in other advice two years ago.

I gave what I consider the contents of the ground, and at the same time advised the directors that they could not run the machinery more than five months of the year. The output for the remainder of the year would have to depend on 'calabashing.' Much was made by the chairman of the fact that I did not accept an invitation to visit the mine when Mr. Hunter was there. I was prepared to return and justify my report in February 1913, but could not do so nearly a year later when I was in the service of another company and unable to get away.

Naraguta, Nigeria, July 25. A. W. HOOKE.

[We are glad to give publicity to this explanation. Our sympathies are strongly with the engineer whose estimates are withheld because they do not confirm those of the promoters, and we are confirmed in our belief that choosing a client, like picking your grandfather, is a delicate matter.—EDITOR.]

Real Estate in London

The Editor:

Sir—Your story in the issue of August 1 about the American visitor who was astonished at the Englishman being willing to maintain a little-visited museum in the heart of a district where land is valuable can be more than matched by an example visible from the office of *The Mining Magazine*. The American in your anecdote wondered that we could afford to devote land in a central district to the Museum of Practical Geology in Piecadilly, seeing that the galleries are as a rule absolutely deserted. But the Museum fills its functions. If it is not always crowded with sightseers, it affords the much-cherished opportunity to the genuine student, and the staff renders invaluable aid to all genuine enquirers on mineralogical and petrological subjects. The museum may therefore be said to fully earn its rent.

Now for my own example of London liberality. Salisbury House forms one of the quadrants of Finsbury Circus. The adjoining quadrant consists of London Wall Buildings. On the northern side is the building of the Institution of Mining and Metallurgy, the London Institution, and Broad Street Place. In the centre of the Circus is a garden of oval shape and covering exactly two acres. Here we find plane-trees, sycamores, aspens, fig-trees, lilacs, and hawthorns, flanking a velvety lawn of the greenest grass, in which are flower beds containing masses of fuchsias and scarlet geraniums, with wild flowers such as iris and willow-herb. The western corner is reserved for the use of children. Here is a playground and a sand-pit. Though in the centre of the richest city of the world, there are no rich children to play in this sand-pit. It is occupied by and is for the benefit of children in poor circumstances, the children from the humble streets adjoining City Road, and the children of the housekeepers who protect the mighty palaces of commerce during the night time and the week-end. Here is a quarter of an acre of ground worth I don't know how many millions devoted exclusively to poor children. Many a time have I drawn the American visitor to my window and shown him the merry crowd of shouting children in the sand-pit under the trees, and have told him the story as I am telling it to you now. The invariable comment is: "Gee! but it's a great country, is England!"

London, August 17. EDWARD WALKER.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE FINENESS of the Mexicon peso is 902.7 parts per thousand, as against 900 for the American dollar, and 925 for the English shilling.

BULLION SCALES are not always available. To convert avoirdupois pounds into troy ounces, multiply by 14.585. To convert kilos into troy ounces, multiply by 32.154.

SILVER may be alloyed with aluminum to produce a white mixture capable of taking a high polish, and of offering considerable resistance to the oxidizing effects of the atmosphere.

THE INTERNATIONAL LEAD REFINERY at East Chicago has a capacity of 5000 tons of metal in 25 days per month, producing common lead, corroding lead, antimonial lead, and doré bullion.

RHODESIA is essentially a country for the small owner. Out of about one hundred and eighty producing mines, over one hundred are milling an average of less than five hundred tons per month.

A MANAGER of a dry-crushing mill has the men sweep the plant with brooms every morning. He states that it costs him nothing in the way of wages, as it requires only a few minutes' time on the part of each man to clean up his particular department. This manager says it not only helps to keep down the dust, but improves working conditions, and results in greater accomplishments on the part of the men. He says they are more energetic and more careful when working in fairly clean surroundings.

RACKS should be provided for the storage of slings and other hoisting accessories about mines. The equipment can thus be more readily located, floor space is saved, and stumbling accidents prevented. In foundries, molten metal is apt to spill on slings if they lie about; this has a tendency to erode and weaken them, and further damage is done in the attempt to forcibly remove the spilled metal. Moreover, they are likely to be bruised, hard to find, and are more susceptible to rust when lying upon the floor.

CELESTITE, strontium sulphide, has at present no market. A very small amount of this material is used in connection with fireworks, but the quantity is so limited that it is not important. Celestite is used in connection with sugar making, and the supply comes from England. American plants, however, arrange to use lime instead, and unless some sugar company could be persuaded to take up the matter and change its process, it is difficult to see how miners could get into the trade. Lime, of course, is very cheap and they would have to be prepared to meet competition at low prices.

SINKING DRIVING, AND RAISING proved that the value of ore indicated by diamond-drilling at Ajo, Arizona, was very accurate. The channel samples of test pits in carbonate ore averaged 0.005% lower than corresponding diamond-drill samples; the test pits and raises in sulphide ore averaged 0.05% lower than corresponding diamond-drill samples; and the drifts in sulphide ore averaged 0.26% higher than the assay value of blocks of ore through which the drifts were driven, as indicated by drill holes at the corners of the blocks. In making the ore estimate, diamond-drill samples were accepted wherever drilling was done, and channel samples of test pits were accepted where sinking was done in advance of drilling.

THE BEST RATIO OF FLUXES to be used with any particular cyanide precipitate is best determined by taking a number of assay crucibles and packing these in the melting furnace, as for assaying. Several weighings of equal amounts of precipitate are then made and fluxed with varying proportions of fluxes and oxidizers. These are then wrapped in thin paper cones and melted in the ordinary way. The time taken for complete fusion should be noticed in each case. After pouring, the slag should be examined, and if necessary assayed for beads of shot, the fluidity of the charge having been noted in each case at the time of pouring. The metal produced from the several tests is weighed and roughly assayed, the fluxes used to obtain the best results being noted for future reference.

THE INACCESSIBILITY of a large number of mining properties complicates the engineering side of the question of mill design. Where mules are the only means of transport, the weight of machinery parts must be restricted to a minimum, and must be sectionalized almost every piece of mine equipment. In some cases this means nothing more than an increase in the initial cost of the machinery. In other cases it means a considerable loss in efficiency when the machine is in operation. Some machines sectionalize well and are thoroughly efficient when erected; others are failures. Again, some machines sectionalize so that freight charges are normal, and the parts make convenient *cargas;* others sectionalize badly and transport costs are out of all proportion to the increase in weight of individual pieces. The weight and shape of wearing parts sometimes make running costs abnormally high.

MINING IN THE FAR NORTH*

The Koyukuk Mining District

By EMIL EDWARD HURJA

With a position farther north than any of the other northern mining districts, the Koyukuk has a higher per capita gold output than any other camp in Alaska. Recent finds made on Hammond river, in deeper gravels than any worked heretofore, have drawn the attention of prospectors and mining men throughout the North to it. There is a natural tendency among the men of the Koyukuk to look with disfavor upon any influx of outsiders. Because of its remoteness and difficulty of access, the district has had an even population for many years. Gold dust still is largely the medium of exchange.

Placer gold was first found in the Koyukuk between 1885 and 1890, when prospectors from the Yukon did some work on smaller tributaries. Gold to the extent of $4000 was mined on Hughes and Florence bars. Nearly all of the tributaries of the Koyukuk in the headwaters have been partly prospected, but on the tributaries of the middle fork the most work has been done. Placer mining is most uncertain in the Koyukuk, because of the character of the ground. Hammond river, in particular, is of interest because of the recent discoveries there. Big boulders offer the greatest hindrance to underground mining, drifts on bedrock being run according to the position and size of the boulders. The high cost of transportation has been the greatest factor in the slow development of the district.

The Koyukuk district is considered to embrace all the land drained by the north, middle, and south forks of the Koyukuk river, lying approximately between 65 and 68° north latitude and 149 and 150° 50′ west longitude, and covering an area of about 4000 square miles. On Chapman creek, tributary to the middle fork, considerable work has been done in years gone by. The stream empties into the middle fork about one-fourth mile above Tramway bar, one of the earliest sources of placer gold in the district. Twelvemile, Rose, Porcupine, Slate, and Myrtle creeks, all tributary to the middle fork, have been prospected, and some of them have even produced some gold. Myrtle creek, with its wide deposit of shallow gravels, has been worked nearly every summer. A small hydraulic plant operated there for a year or two. Emma creek is said to have produced nearly $200,000 from 1900 to 1910, but very little work has been done since that time. Des-

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29. Mr. Hurja in subsequent letters will give full accounts of present conditions in each of the great producing districts of the Far North.—EDITOR.]

SCOWING ON THE KOYUKUK.

uitory prospecting has been carried on during the past few years. On Wiseman creek, a tributary of the middle fork above the town of Coldfoot, what are probably the deepeat placer shafts in Alaska have been put down without succeas. One is 280 and another 335 ft. in depth. Nolan creek has produced many thousands in gold, but very little work is being done there now.

Hammond creek or river is 45 miles long. it is a tributary of the middle fork from the northweat. The first rush to the Koyukuk because of the Hammond River finds was in 1900, and the second and iesser one in 1911. John Boman and S. Sehofield, on 4 Above, last winter mined a dump estimated at $40,000. During a short space of time early this spring, they picked up in the bottom of their shaft $24,000 more in coarse gold. The 'pay' is from seven to eight feet in height, and $100 pans are not uncommon. Redmond, Murray, & Kinney have a lay on the ground above, but are having some trouble prospecting it because of the water. It is costing the laymen $30 per foot to work the ground. The Haiser ground, farther downstream, is being worked by Knute Ellingsen, F. Wilson, and Jack Haiser. An average of $100 per day was picked up in nuggets on bedrock this spring. Vernon Watts, on his property, found gold in his second hole and in one day picked up $400. Cassiar Jim has found pay-dirt in a prospect hole back of Hasting's messhouse. Plummer has purchased the interest of Harry Foley in the Peter Dow ground, downstream from the Bowker brothers' holdings. Plummer lost $8000 by his season's work.

On Vermont creek, some work is going on. Gold creek is somewhat active, Johnson & Latimore, and Thompson & Buttovich having found workable 'pay' during the winter. They were starting to sluice their dumps early in July. Hughes and associates have found 'pay' on Linda creek. A shaft sunk by James Brandon and partners on Jim Pup, a tributary of California creek, yielded $559 from the bottom. Collins & Dingei sank a ho'e at Wiseman and reached bedrock at a depth of 267 ft. At the 235-ft. depth, they found 5 ft. of sc. gravel and have now started a level there with the intention of working this. James Tobin put down a 227-ft. hole on Bettles river, an eastern branch of the middle fork, but found no bedrock. Gold bench, of the south fork of the river, is deserted now. It has produced about $150,000. Prospecting on the north fork of the Koyukuk is centred on Mascot creek, Wild river, and John river. Nothing of great import has been found so far. Coldfoot, at the mouth of Slate creek, until 1904 was the supply centre of the mining district. Then it was moved upstream 16 miles to Wiseman, where the United States commissioner's, deputy marshal's offices, the postoffice, and stores are.

Bettles is the head of navigation on the Koyukuk river, 515 miles from the Yukon. At a high stage of water steamboats travel with freight and passengers as far as Bettles. From there to Wiseman, 85 miles farther upstream, the stream is narrow and shallow, and horses are necessary to pull the loaded barges over the bars. There is some agriculture near Coldfoot and Wiseman, despite the fact that it is from 60 to 75 miles north of the Arctic Circle.

The Koyukuk district has been assisted less by outside capital than any district of Alaska. Its population is kept down because every person in the district has to work, and there is work for but a very limited number of men. There are probably 200 miners in the district now. The production in 1913 is estimated at $200,000; the season was backward because of the late winter and the consequent lack of water for sluicing purposes. The total production of the camp from 1900 to date is estimated at $2,894,300. The gold is of a very high grade, being worth from $18 to $20. Nuggets are common, chunks weighing from $50 to $1500 having been found. About 50% of the total output has been paid out in production costs. Equipment in the Koyukuk is nearly all of the patchwork variety, made up of odds and ends of machinery. Ordinary manual labor is paid from $4 to $6 per day, with food, which costs from $3 to $5 per day per man, depending upon the district. The annual outfit for a miner in the Koyukuk district is estimated to cost $1000. Steamers of the White Pass company make two trips to Bettles each summer. In winter, two trails are used, one by way of the Chandlar and the other by the Tanana. Freight rates from Seattle to Bettles are from 4 to 6 cents per pound, and from Bettles to Wiseman from 6 to 8c. per pound, or a through rate from the outside of from $200 to $280 per ton.

The Koyukuk region has been described by A. G. Maddren in *Bulletin* 532 of the United States Geological Survey. The first studies made in the district were those of F. C. Schrader, whose report was published in 1899. The northern part extends into the Endicott mountains, which form the watershed between the Yukon and the Arctic drainage. The southern part consists of the Koyukuk flats, a broad basin lowland. The crest line of the mountains is about 6000 ft. above sea-level, but peaks rise to 9000 ft. The mountains consist of altered Paleozoic limestones and Argillites.

HAMMOND RIVER GOLD CLAIMS.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

HOUGHTON, MICHIGAN

CURTAILMENT OF OPERATIONS AND REDUCTION IN WAGES AND SALARIES.—TAMARACK REGRINDING PLANT.—WHITE PINE PROPERTY.—TAILING TREATMENT.—CENTRAL PORTION OF DISTRICT.

The effects of the European war upon the Michigan copper industry are now beginning to be more seriously felt. If the war is continued for any length of time, Michigan miners will face a graver situation this coming winter than they experienced during the strike of last year. A great many of the men have not recovered from their losses of that period, and with the additional curtailment of operations in the district, they certainly have before them a most serious situation. While suspensions and curtailments of operations were announced early in August, Michigan so far has not suffered as seriously as the western districts. On August 6 the Winona property was shut down. That this action was necessitated was deeply regretted by the people of the copper country, in view of the fact that successful experiments have recently been completed with a new regrinding machine, and a leaching process was also under consideration. The following day operations were temporarily suspended at the Hancock Consolidated. This property had just reached a point where it was paying expenses, and work will be resumed as soon as possible. On August 15 the Baltic, Champion, and Trimountain mines, of the Copper Range Consolidated, were closed. It was announced at that time that the properties would reopen September 1, and continue operating on full time until September 15, when they would suspend work again until October 1. It was also stated that the pay of miners and trammers and all other employees would be reduced. A curtailment of the production of the Calumet & Hecla properties has been expected for some time. Beginning September 1, all the mines, mills, and smelters of this company will be operated three-quarter time, and the rate of wages existing immediately prior to May 1, 1912, when an increase of 10% was given the men, will become effective. A reduction of 15% in the pay of the officers and all those not affected by the increase of May 1, 1912, will be made. A similar reduction will be made in the pay of all officers and employees of the Boston and New York offices. Work on the leaching plant and the new regrinding mill for the stamp sand has been suspended, but the dredge is nearly ready for operation. It is expected that on September 1, the Quincy will order a 50% curtailment of production. A decrease in pay of 12½%, beginning on the above date, has been announced. The Tamarack has suspended work at its two operating shafts, but work on the new regrinding plant at Hubbell is being continued.

In the latter part of April, directors of the Tamarack voted to proceed immediately with the construction of a regrinding and leaching plant for the treatment of the large pile of stamp sand at the mill on Torch lake. The construction of the concrete foundation of this plant is now under way. The Tamarack sand has been accumulating for about 30 years and represents a tonnage of about 11,000,000. It contains about 12½ lb. copper per ton. It has been estimated that by the new process of regrinding and leaching, 9 lb. per ton can be recovered at a cost of about 6c. per pound. This shows a total profit of about $8,000,000. Until recently all the Calumet & Hecla smelter product that was treated electrolytically had to be shipped to its plant at Buffalo, New York. This eastern plant has been disposed of and the copper is now treated at a recently erected model electrolytic refinery at Hubbell.

At the extreme southern end of the district, the C. & H.'s White Pine claims are now making a success of mining the Nonesuch sandstone on property which was tested over 30 years ago. Ever since the C. & H. took up this property some five years ago, successful exploration work has been carried on. Four shafts have been sunk and three are being operated. About 100 acres of land has been cleared on which the Company has erected more than 30 buildings. A sawmill is in operation which turns out 12,000 ft. of lumber per day. Within a year the Company expects to have completed a modern and well equipped mill on the Mineral river. An electric generator will furnish power for 2 gyratory crushers, 64 Wilfley tables, and 12 conical mills. The water for the mill will be supplied by an electric pump a mile west on Iron river. The success of the White Pine is of great interest to the people of the copper country in that it opens up for profitable development a large area of unexplored land at the southern end of the district. At the northern end of the district, near Phoenix, the Keweenaw Copper Co. is actively exploring by diamond-drilling and shaft sinking, the old Ashbed lode. The shaft is now being sunk on the site of an old hole put down some 50 years ago. If, as a result of this revived interest, the Ashbed lode should prove profitable on deeper exploration, the two sections of the district where copper was first mined, one at the north and the other at the south, will again be producing.

Regrinding Hardinge conical mills have been in successful operation for some time at the Copper Range Consolidated mines. Electric haulage was adopted in the Champion mine after proving a success at the Baltic. A sand-filling system is in operation at the Champion. This saves the cost of blasting down poor rock to give the miners a footing in the stopes, and also disposes of the waste stamp sand. The sand is carried from the mills by rail to a small shaft at the bottom of which is a large pipe leading to various parts of the mine. At the end of the pipe the sand is blown out into the openings by compressed air. At the Winona, regrinding mills were installed and proved a success in handling the mill tailing. However, a considerable amount of the copper was still not recovered, so a series of experiments was made with the Lovett grinder. The Winona rock averages about 20 lb. of copper per ton, but because of the flaky character of the copper, only about 12½ lb. per ton has been recovered. By the Lovett process the copper is rolled into minute balls and slugs, which are more easily recovered on the concentrating tables. The experiments show that about 80% of the copper in the Winona rock, or about 16 lb. per ton, can be recovered by this process. Two leaching processes for Winona mill tailing have also been considered by the management.

In the central part of the district extensive exploration work has been going on at several properties. Large rockhouses for storage purposes have been built at a number of the mines. The Hancock Consolidated reached a point this summer where it was paying expenses and last winter the Isle Royale paid its first dividend of $1 per share after 50 years of operation. Over this active and producing mining district the great European war has cast its shadow. The Hancock and Winona have suspended operations, the Copper Range mines are running half time and practically all new construction work has stopped.

LONDON

REVIEW OF THE METAL SITUATION, ESPECIALLY SPELTER, TIN, AND TUNGSTEN; SOME INTERESTING 'INSIDE' INFORMATION ON THESE METALS.

The metal markets of the world have, of course, been badly disorganized by the war in Europe. Much has been said in the *Press* on the subject, but it is probable that I shall be able to supplement that information in the case of zinc, tin, and tungsten.

As regards zinc, the most important interest in the British Empire is that centred at Broken Hill. The zinc concentrate produced there is almost entirely sold to Continental buyers, who distribute it, in a way impossible to follow here, among Belgian and German smelters. As mentioned in the last letter, the efforts of Broken Hill producers to treat their concentrate have ended in comparative failure. At the present time Broken Hill has no outlet. Welsh firms are not prepared to increase their plant to cope with the now plentiful supply. We do not know how long the war will last. Moreover, whether Germany loses or wins, she will eventually be in an improved position for handling all the zinc material offered. Thus the Swansea people are inclined to go slow. Perhaps the Broken Hill groups, Zinc Corporation and North and South mines, may be able to combine and complete a long-cherished scheme by erecting a smelter in South Wales. The Burma Corporation would join them in evolving a scheme for smelting complex zinc-lead sulphides. In reviewing the present position of zinc smelting in South Wales, it is of interest to note that the German firm of Aron Hirsch & Son acquired the works of the Swansea Vale Spelter Co. two years ago and has spent large amounts of money in erecting modern plant. This move would tend to show that the conditions as regards labor and fuel in South Wales do not suffer by comparison with conditions on the Continent, so that the establishment of works in Swansea district for the treatment of Australian concentrate is well within the bounds of possibility. But a large expenditure would be required, and there are few people with both sufficient knowledge and funds. Undoubtedly, H. C. Hoover is the man to do it. Some people have proposed that Broken Hill sulphides should be shipped to the United States for treatment, but surely the cost of freight would be prohibitive, and the extra output of metal could not be absorbed or shipped to Europe at a profit. It is of interest to note that the two German zinc districts are at the opposite ends of the empire and are in the two theatres of war. The Prussian zinc industry centres round Aix-la-Chapelle, and the ores treated belong to the same mineral region that provides material for the Liége smelters over the borders in Belgium. The Silesian industry is situated at the far southeast corner of Germany abutting on Po and and Galicia. This country is inhabited by Poles and in fact is called German Poland. Part of the military scheme of Russia is to capture the whole of this territory. Roughly speaking, a line drawn from Danzig to Posen and from Posen to Oderberg encloses the Polish part of Germany that is desired by Russia.

The tin-smelting industry of this country has been utterly disorganized by the war, owing almost entirely to closing of the Metal Exchange. It is commonly supposed that this Exchange exists for the purpose of bringing together the producer and consumer. Unfortunately this is a myth. Its present function is to enable middlemen to fight each other, and incidentally to damage the mines and the users of the metals. When the Cornish mines offer their tin concentrate at the 'fortnightly ticketing' at Redruth, the price at which the contract is settled depends on the quotation at the London Metal Exchange. Since the declaration of war the Exchange has been shut, so there are no quotations, and a deadlock exists in Cornwall. It is true that the Exchange has been open in a restricted sense, for the purpose of squaring old commitments among members. But the Exchange has such cosmopolitan interests, with members representing buyers and sellers in all countries ranged on one side or other of the present war, that it is difficult to bring settlement out of chaos. It was of little use trying to arrange a price for Cornish contracts, and it was obvious that smelters were not inclined to make any offers for purchase except at a speculatively low price. The mines have so far rejected the bids, and the concentrates are accumulating. The firm of Bolitho, once bankers but now merged in Barclays, and until recently tin smelters at Penzance, have offered to advance money on the security of the concentrates, in order to enable the mines to keep working. It might be supposed that the closing of the German market for tin would induce other buyers to go ahead, but the South Wales tin plate makers have been holding back, and the American shipments from England are effectually checked by the stringent terms imposed by the British Government to prevent the reshipment of metal to Germany. As regards the supplies of tin for Germany, comparatively little is produced locally, chiefly in Saxony. Of imported ores most has come from Bolivia. It is probable that some of this Bolivian ore may be offered to Cornish smelters who have works at Liverpool, but at the present time these smelters are averse to entering into new contracts.

As regards tungsten, wolfram ores have always gone to Germany for treatment. There has never been a large enough home supply of wolframite to make it worth while for English metallurgists to take the trouble, and if a German firm was willing to do the work, the Englishman was content to let it be so. Tungsten is largely used for tool steel at Sheffield. The most interesting, though restricted, application is for producing the filaments for incandescent lamps. It has been a long and tedious business to make a tough and well-cohering wire of tungsten out of the fine powdered precipitate produced in the chemical reaction, and it is to the credit of the laborious German chemists that a satisfactory wire has been manufactured. It is not probable that English firms will undertake the production of tungsten products. More probably they will adopt alternative methods of obtaining the same results in steel and light.

NEW YORK

RESUMPTION OF WORK AT SEVERAL MINES IN MEXICO.—COPPER MINES AND OPERATIONS.

Mining conditions in Mexico seem to be rapidly improving. The American Smelting & Refining Co. re-started its plants at Chihuahua and Monterey about three weeks ago, and now has them running at about one-third capacity, or 150 and 100 tons per day, respectively. The chief trouble is the one which has been most serious for the past two years, namely, that transportation can not be depended upon. Another difficulty is that many of the former employees have left the district, so that when operations reach full scale it will be necessary to take on men new to the work. The Mines Company of America now has both its Creston-Colorado and El Rayo mines working, and when railroad conditions are better the Dolores and La Dura may resume. Epes Randolph is reported as expressing the belief that the Southern Pacific lines in Mexico would soon resume operations, Charles Hoyle now being manager. It is reported that the Mexico Mines of El Oro and the Dos Estrellas will be working again by the end of the month. Political conditions in Mexico are completely obscured by the European catastrophe. There is also very little mining news available in New York now. The stock market is the great cause for getting news here promptly, so that the supply of news has gradually dwindled away.

The copper situation is surprisingly good, considering the

possibilities that it exhibited a month ago. Most of the statistics which can be suppressed have been withheld, but the Custom House figures for August show that 38,302,000 lb. copper was exported last month. As this is more than half of the average for recent months, and is two-thirds of the monthly average last year, it is decidedly encouraging, as the difficulties of carrying on ordinary business have been almost insuperable. Correspondents abroad cannot be reached by cable in many instances, and it is impossible to obtain exchange at reasonable rates or even at any rate at all, while freight and insurance rates are equally prohibitive. It is impossible to learn how much copper domestic consumers

NEW MILL AT INSPIRATION AS SEEN FROM TRESTLE OF RAILWAY BETWEEN MINE AND MILL.

are taking, but the American Brass Co. is said to be operating at three-fourths normal capacity. It has all along been expected that a further reduction in output of the mines would be necessary, but if conditions continue as favorable it may be avoided. Several of the large companies have passed their dividends, and in other cases there was not a quorum at the company meeting, so that action was postponed. The Wolverine has declared a dividend of $2 per share, but most of the other companies are keeping their cash. The mines and mills of the Calumet & Hecla company are now being operated three-fourths time, and the wage scale of 1912 has been restored, while the pay of all the officers of the Company has been cut 15%. The No. 5 shaft of the Osceola has been stopped, and the La Salle has shut down. The Quincy has made a 12½% reduction in its wage scale and a corresponding reduction in its output. Reports from eastern Canada are somewhat depressing.

LEADVILLE, COLORADO

EFFECT OF THE METAL MARKET ON THE DISTRICT.—OPERATIONS AT THE WOLFTONE, LITTLE JONNY, NEW MONARCH, IRON & SILVER, AND YAK TUNNEL PROPERTIES.—NEW MILLING PROCESS.

The recent depression in the metal market affected mining in Leadville and the surrounding district as it did in many other parts of the country. A large proportion of the value in the ore here is in the silver, and when there was no regular market a number of the mines were compelled to reduce production or close. The Dinero tunnel, which is one of the most extensive silver producers of the district, was shut down, as were the Louisville and Virginius. This state of affairs is only temporary, and since silver prices have showed a tendency to rise steadily, and the smelters are again settling for ore at the full amount of quotations, a number of mines have resumed their regular output, with others to follow soon. Mining and smelting men of the district are enthusiastic in their belief that the price of silver is going to reach a high mark, and many of them are optimistic enough to assert that the white metal will be selling for $1 per ounce before the end of the year. In connection with the future price of silver a strong move is being made by the most influential men of the state to have silver placed on a basis of a 22 to 1 ratio with gold, and this price made the standard.

The zinc-producing properties of the district continued their operations in a rather uncertain manner for some time, but none of them in any way reduced their output. The new zinc oxide plant was closed down as mentioned in 'The Mining Summary' of recent issues of the *Press*.

In the Wolftone property of the Western Mining Co., the largest producer of zinc carbonate in the state, has been opened another great body of that ore. A drift has been driven over 200 ft. in carbonate, and the body averages 60 ft. in height. The mine has been shipping 500 tons per day for several years, and many people thought that it was about worked out. This new development adds to the already remarkable history of the famous mine, and it is now assured of two years of activity at its present rate of production. All of the ore that has been produced to date has averaged nearly 30% zinc. By the time this new body is mined there will be a market for the immense deposits of low-grade material which still remains in the property.

Lessees of the Little Jonny mine of the Ibex Mining Co. are making a great deal of money from gold ore, as shown in 'The Mining Summary' of the *Press* from time to time. The property as a unit is producing more ore than any other one concern in the district. About 200 men are working on the property, all of them being lessees or in the employ of lessees.

The New Monarch Mining Co., which is being operated on a plan similar to that used on the Jonny, is also producing a large tonnage of good ore. The property recently adopted the leasing system, and several good orebodies have been uncovered. Considerable high-grade ore is being produced in this mine, along with a large output of lower-grade material.

The Iron & Silver Mining Co., which is one of the largest operating companies, continues to produce its regular 200 tons per day, mostly of silver, lead, and zinc sulphide ores. The Company has opened many new veins of ore, and it still has a large tract of new ground to develop as operations proceed. The manager, George Argall, made no changes in his schedule during the time that the silver prices were at such a low mark, and smelters were settling for 25c. per ounce.

The great Yak tunnel is operating at full capacity. It has been advanced well into Mosquito range, but owing to inability to secure leases on the adjoining claims, progress in the breast has been suspended. Many of the claims which have been undermined by the tunnel are now being worked through this new and handy means of approach. It is one of the largest concerns now operating here and employs several hundred men.

The newest thing in the mining industry of the district came to light just this week when William J. Candlish, a Leadville man prominent in mining and political circles in the state, made known his invention of a milling process which will treat the low-grade sulphide ores. His process is a combination of gravity elimination and the pulsating jig. It will treat zinc, iron, and lead ores, and Mr. Candlish states that he is assured of 80% efficiency in separating these from each other. He has erected a mill which will be ready to begin the actual grinding of ore within 30 days. The mill has a good arrangement. From the time that the ore is unloaded from the railroad cars into the receiving bins until the product is discharged into the shipping cars, it is not handled once. The system of chutes, conveyors, and elevators which Mr. Candlish has installed carries the ore through without trouble. There is also an unexpected lack of intricate machinery and driving belts such as are usually to be found in a plant of this type. Everything is based upon simplicity and economy, and for that reason a much lower grade of ore than has heretofore been handled will be sought. The first unit of the plant, which is about complete, will have a capacity of 100 tons per

day and will have 10 separating machines. Other units will follow rapidly, and several mills will probably be erected on many of the mining properties where suitable ore is being mined. The Lackawanna district is producing a good tonnage of high-grade gold ore. No milling is being done there now.

WASHINGTON, D. C.

PROPOSED BUREAU OF LABOR SAFETY AND EFFECT OF ITS WORK ON THE BUREAU OF MINES.—MINING MAN ON THE INTERSTATE TRADES COMMISSION.

The uneasy feeling over the possibility of the passage by Congress of the bill to create a Bureau of Labor Safety in the Department of Commerce is quite warranted from the looks of things; but inquiry at the Capitol discloses that the movement back of the bill has no other force at present than a little play on the part of Senator Shively of Indiana, for political effect at home. He is a candidate for reëlection, and the labor forces are strong in votes in his state. They must be tickled. He has reported the bill out of the Committee on Education and Labor of the Senate and placed it on the calendar of the Senate, but it is being said that the bill will repose there for some time. In the present stage of legislation the bill can only be passed by unanimous consent, and as the bill is opposed in the Senate and so would occasion discussion, its prospects of immediate passage seem remote. It is admitted by those who are disposed to oppose any legislation which would take from the Bureau of Mines its own management of the direction of safety work in the mines that it understands the Shively movement to have no other design than to make a political play, which is not to extend so far as the enactment of the bill. The Labor Department is ambitious. It is now one of the smallest of the departments in Washington, and a bureau of safety with a good deal of the activity of the Bureau of Mines in its control would suit its appetite admirably. The Bureau of Mines fears that it may be transferred entirely to the Department of Labor from the Department of the Interior; and indeed a bill to that effect has already been introduced in the House by Congressman Casey of Pennsylvania, with quite a screaming interview in support of the bill. The Bureau of Mines feels, and most mine owners and operators with it, that the proper place for this department, the value of whose work they recognize, is in the Department of the Interior rather than in the Department of labor, which is recognized as an adjunct of organized labor rather than a scientific branch of the Government of the United States. It is feared that under such control the Bureau would be operated in favor of the miners rather than for mining in general as a scientific and business proposition. It is indeed conceived that such control would be intolerable.

As has been stated, there can be no denial that the general principle behind the idea to create a Bureau of Labor Safety in the Department of Labor is admirable, and the probabilities are that in the long run such a bureau would be created, but inasmuch as the Bureau of Mines already exists, and gives its attention and operates safety devices in the mines for exemplification purposes, and by force of law if necessary, it would be better if the Bureau of Mines were excepted from the proposed law. This might in a sense be duplicating work, but it is one way of reaching a practical result. Both needs and desires could thus be most satisfactorily met. Probably this will be done. Meanwhile attention will have to be directed to the Casey bill, so that it may be thwarted.

The idea broached that a mining man should be on the Interstate Trades Commission which Congress is to create, should be given impetus. The greatness of the mining industry has been set forth and needs no repetition. However, the mining world has not been disposed to blow its horn very much except on the labor side, and so it has not been felt as an influence that should or must be consulted. If the mining world really wants to be represented on the trades commission it must make itself heard in a substantial way; but the energy must be directed not in support of some particular man to represent the mining world, but in support of the idea that the mining world should be represented on the board. That would be more than half the battle, if established. President Wilson is adverse to having men pushed upon him for appointment. He likes to do his own consulting and choosing, and he can be depended upon to look in the right direction for advice. If there is any campaigning at all it must be done for a group of desirable men, not for one man only. It is proposed to absolve mines from assessment work this year; the usual attempt made on the least excuse.

TORONTO, ONTARIO

FURTHER NOTES ON THE SILVER SITUATION AT COBALT.—CITY OF COBALT AND CROWN RESERVE MINES.—MINERS OFF TO WAR.—PORCUPINE NOTES.—CANADIAN IRON AND STEEL PLANTS CLOSED.

In addition to others, the Buffalo, Kerr Lake, and Drummond Fraction mines of Cobalt have closed down owing to the state of the silver market and the action of the American Smelting & Refining Co. in only advancing 25c. per ounce on silver. Other companies are curtailing their output considerably. The Cobalt Mine Managers' Association is taking active steps to bring about some arrangement under which sufficient money can be advanced to keep producing companies in operation. The matter has been taken up with the Hon. W. T. White, Canadian finance minister. The proposition is made that the Government should accept silver bullion as collateral and empower the banks to pay the companies the cost of operations in cash, which would enable them to meet current liabilities. As soon as the silver can be marketed to advantage, the mining companies will sell and repay the loans. It is probable that this scheme will be adopted. A favorable change in the situation has taken place with the resumption of bullion shipments, the express companies now accepting consignments for trans-Atlantic shipment at the same insurance rates as before the war.

Shareholders of the City of Cobalt Mining Co. have adopted a resolution providing for the voluntary winding-up of the Company, which has been merged in the Mining Corporation of Canada.——The Crown Reserve has cut a vein containing high-grade ore. The management has no present intention of curtailing operations. The usual monthly 2% dividend has been declared.

Many miners and prospectors of Cobalt and other silver districts have joined the Canadian contingent which will shortly leave for the seat of war. Those of them who have assessment work on claims falling due have been assured by the Ontario Government that all necessary extensions of time to enable them to secure their titles will be granted. A general extension of three months for assessment work on all Ontario mining claims on account of the prevalent financial stringency is being asked for, and will probably be accorded.

The Rea company has been reorganized as the Porcupine Aurum, with an authorized capitalization of 1,000,000 $1 shares. It retains 50,000 shares in the treasury and has also $40,000 in cash. Bush fires have been ravaging the country around Porcupine, and the plants of the Foley and Little Pet were destroyed.

The iron and steel industry has been paralyzed by the war, and the plants of the Dominion Steel Co. and Nova Scotia Steel & Coal Co. have been closed. The latter Company has also curtailed ore-mining operations at Wabana, Newfoundland. The works of the Algoma Steel Corporation at Sault Ste. Marie will run at half time beginning September 1.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

The discharge of the Yukon river at Eagle, which is just on the boundary of Alaska and the Yukon territory, is discussed in Water-Supply Paper 345-F of the U. S. Geological Survey, by E. A. Porter and R. W. Davenport. The Yukon is the fifth longest and has the fifth largest drainage area in North America, being 2300 miles long with a drainage area of 330,000 square miles. It rises in the northeastern part of British Columbia, flowing northwest and then southwest to the Bering sea. Up to Eagle the drainage area is 122,000 square miles. The mean annual temperature here is 23.7°F., varying from −23.6 to 59.6°. The mean rainfall of the Yukon basin is about 11.5 in. The break-up of ice at Eagle is during the first two weeks of May, and the freeze-up in the first three weeks of November. The average monthly discharge there in 1913 was 73,500 second-feet, ranging from 11,000 to

MAP OF ALASKA.

199,000 ft. The greatest discharge recorded was on May 22, 1911, when over a width of 1645 ft., and a depth of 28.7 ft., a surface velocity of 8.55 ft. per second, or 5.8 miles per hour, was 253,000 second-feet. This publication is interesting and valuable to Alaskan people.

The marble resources of Juneau, Skagway, and Sitka districts of the territory are described in *Bulletin* 592-C of the U. S. Geological Survey, by Ernest F. Burchard. The publication discusses the types and distribution of the rock, topographic and commercial relations, geologic relations, and the deposits of Limestone inlet, Glacier bay, Chichagof island, and Admiralty island.

Fairbanks

According to Frank Cook, agent for Wells, Fargo & Co., the output of gold from the immediate Fairbanks district for May, June, and July was 16,630, 41,031, and 23,853 oz., respectively, worth $1,462,931. The yield for the same period of 1913 was 17,758, 49,140, and 31,596 oz., worth $1,776,117. Sluicing and clean-ups have been started later this year, and a certain amount of gold has been sent out by parcel post. This season's yield is estimated to be equal to last.

Gold from clean-ups on Pedro creek are now going to Fairbanks. The two best returns so far are from Julius and C. P. Gins, who recovered about $18,000 each.——J. McPike, C. A. Deruchia, Mudge & Co., H. Atwood, and others are sluicing.——Good reports come from the Hot Springs district, the largest operator being A. Bock, on Woodchopper creek.——He is working rich ground, and the season's output will be about $200,000.——A. Hilty is clearing muck off his gravel with a Bagley scraper, which is one of the largest in the territory. Preliminary work has been under way for about two years. There is four years' ground ready for washing.

Iditarod

In the suit for possession of the Chicago bench, on Flat creek, which was jumped last winter by Adams and Knox, which ended in the District Court on July 27, Judge Fuller instructed the jury to return a verdict for the defendant, the Yukon Gold Co. The court ruled that the defendant was in rightful possession of the ground and that plaintiffs, Adams and Knox, could not acquire rights by wrongful entry.

Juneau

July returns from the mines on Douglas island were as follows:

Mine.	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Ore crushed, tons	19,803	81,340	37,954
Concentrate treated, tons	347	1,813	912
Total realizable value of gold	$37,939	$224,837	$74,999
Net profit	15,884	133,740	16,347
Development, feet	131	322	1,023
Broken ore in stopes, decrease or increase, tons	—5,013	—57,403	2,698

In the 700-Ft. Claim of the Treadwell company there was completed 403 ft. of work.

Nome

A fierce gale, nearly as severe as that of last year, was raging at Nome at the end of last week. Three steamers managed to put out to sea.

ARIZONA

Gila County

The Calumet & Arizona company has suspended development of the property under option at Globe. A large quantity of machinery was installed for the work, including a transmission line 18 miles long, between Ray and Superior. Everything is to be removed. No reason is given for this move.

Greenlee County

At the Arizona Copper Co.'s smelter only one reverberatory furnace is in operation and the output of metal is only 50% of normal. The mines at Morenci and Coronado are being worked with reduced force. About 1000 men have been laid off. Copper is being stacked at the new smelter.——A feeling of uncertainty prevails at the Shannon mine.

CALIFORNIA

Eldorado County

After a temporary shut-down of two-weeks the Oro Fino mine at Big Canyon has resumed work. This property is owned by English people, and C. H. James is in charge. ——Good asbestos is said to have been opened near Garden Valley by W. H. Leverone.——Rich ore has been cut in the Bumgardner mine near Eldorado. A small mill is working.

Nevada County

A good tonnage of ore has been opened in the Meister, near

Washington, and machinery is to be installed. E. C. Klinker is manager.——Los Angeles people have bonded the Eagle Bird, and are about to start development.

Placer County

Some activity is reported in districts adjacent to Georgetown and Cool. Good gravel has been opened at the Goggins. B. Rymal and W. Young propose to install a mill on their claim at Pilot Hill.

Shasta County

Redding people, comprising the American Mining Co., are preparing to work the old American mine in the French Gulch district. The property consists of 11 quartz claims adjoining the Gladstone, where 30 stamps are working. Ore worth $8 to $23 has been developed by lessees between No. 4 and 5 levels. A 10-stamp mill is on the ground, but must be overhauled.——The United States Smelting company has sent 11 men from Kennett to its property at Juneau, Alaska. These men will be employed largely for diamond-drilling, and include G. A. Little, W. F. Rucker, and G. A. Wommer, of the Mammoth mine.

Sierra County

It is planned to consolidate several properties in Sailor ravine, near Downieville, and to prospect for the Alleghany mineral zone. The claims so joined will have a total length of 12,000 ft., from the base of the mountain at Downieville to the ridge on the south slopes of Monte Cristo peak. They are all in serpentine contact formation. A 12,000 ft. double-track adit is proposed. Fred Bosch, a well-known Downieville miner, is arranging the consolidation. The mines will cost $150,000, of which $50,000 goes to Bosch Bros., and a similar amount to the Jason Frye interests in the Standard mine. A total outlay of $250,000 is estimated. John Hughes proposed this consolidation and had already driven several hundred feet.

COLORADO

Ouray County

The Camp Bird company reports as follows for the quarter ended June 30:

Development, feet	1177
Stoping, cubic feet	76,520
Broken ore in stopes, tons	16,911
Ore treated, tons	7352
Bullion sold	$124,920
Concentrate sold	66,253
Total yield	$191,173
All working expenses	71,038
Operating profit	$120,135
Profit from Santa Gertrudis (Mexico)	19,100

On No. 6 level east No. 2, work at raise A631 east has opened 6 to 7 ft. of profitable ore. In other stopes from 11 to 14 ft. of fair hematite ore was disclosed. Raise above No. 7 level is up 52 ft. showing 3 ft. of ore. On No. 8 level the east heading is out 285 ft. Up to 70 ft. the ground was barren, then fair ore was followed for 60 ft. varying from 18 in. to 10 ft. wide.

San Miguel County

The American Rapid Cyaniding Co. of Detroit, reports that it has installed a D. C. Reinohl 'rapid cyaniding apparatus' at the Suffolk mill, Ophir, operated by the Ophir Gold Mines, Milling & Power Co., of which George B. Pickett is vice-president and general manager.

Ore is run through crushers, then to a stamp-mill where it is further crushed in a cyanide solution and conducted through a tube-mill and reduced to about 200 mesh. The pulp is then delivered to a Reinohl apparatus, comprising a launder and a lixiviator, where the pulp is heated, additional cyanide supplied progressively to maintain its strength, and the pulp continuously agitated in the open. From the end of the lixiviator the pulp is conducted to settling tanks, clarified solution containing the gold and silver content decanted, filtered, and conducted through zinc boxes in the usual manner. A complete cycle of treatment from the ore-bins to the gold solution returned to the stock tank, is said to have been made in 11 minutes. Recoveries indicated 96% of the gold and 98% of the silver in the ores, at a loss of 5% of the strength of the solution. Demonstrations of the process were in charge of A. J. Weinig, metallurgical engineer of the Liberty Bell; while Walter L. Reid, metallurgist of the Smuggler Union, witnessed the plant in operation.

Teller County (Cripple Creek)

The estimated output of the district in August is as follows:

Plants.	Tons.	Average Value.	Gross Value.
Smelters	3,950	$55.00	$ 217,250
Golden Cycle	30,000	20.00	600,000
Portland (Colorado City)	10,000	20.00	200,000
Portland (Cripple Creek)	21,200	2.08	44,096
Stratton's Independence	11,200	2.72	30,464
Colburn-Ajax	4,400	6.75	29,700
Wild Horse	1,300	3.09	4,017
Kavanaugh-Joe Dandy	2,000	2.00	4,000
Gaylord-Dante	1,500	2.50	3,750
Isabella	1,000	2.10	2,100
Total	86,550		$1,135,377

During 1913 the Lexington Gold Mining Co. mined 641 tons averaging $15.22 per ton worth $9771, of which the net return to the Company after paying lessees, was $1385. Assets are worth $5308.

On company and lessees' account, the Vindicator mine produced approximately 3000 tons of ore in August, valued at $98,500. Development is most promising.——Work is to be resumed at the Last Dollar mine, now controlled by the Lews Gold Mining Co., by sinking the main shaft from 1300 to 1500 ft., and 200 ft. of driving. J. B. Page will be in charge of mining operations, while Robert E. Cranston is consulting engineer. The output to date is about $2,500,000.——Lessees at the United mines produced 350 tons in August. Prospecting at 175 ft. in the Fortuna, under George Harris, is encouraging.——The Acacia shaft is to be sunk from 1110 ft. to 1260 ft. Rich ore is being opened on No. 11 level. The August yield was 175 bars. Kenneth MacKenzie is manager. ——The Dillon shaft of the Granite company is down 1260 ft. Seepage water in the Gold Coin shaft is under control.

San Juan—La Plata—Mineral—Park Counties

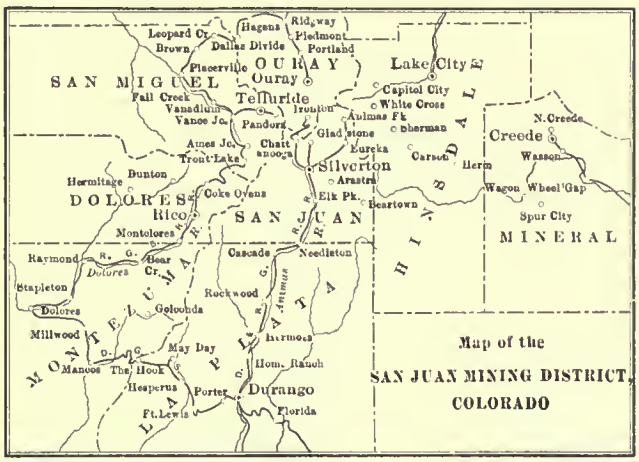
During a recent trip to Silverton and Creede, our correspondent made the following notes:

There seems to be quite a little going on in Silverton, although the people there are complaining of dull times, as everywhere else.——The Gold King, Sunnyside, Iowa-Tiger, Silver Lake, Highland Mary, Shenandoah, and several smaller properties are producing right along.——The Buffalo Boy group is under option to somebody, presumably the Tonopah people, and the general local impression is that the deal is going through, which will mean another comparatively large producer before long, if it turns out as well as is expected. ——The slime plant which is treating old tailing that is being pumped out of Silver lake and piped down to the river is said to be working well, but the officials hope to improve it by adding flotation methods to those already in use.—— The electrostatic plant at the Sunnyside is also said to be doing good work, and it is said that the owners were experimenting with the Plumb jig, as shown in the *Press* of May 23, with a view to using it instead of the present method.—— People in Silverton are somewhat wrought up by the proposal of the postoffice authorities to discontinue the mail

route to Ouray. This would mean that if the railroad to Durango is out of commission, which it is for some period nearly every winter, they would be without mail facilities. Naturally they are doing everything they can to have the service to Ouray continued.

Nothing could be found out about the alleged new discoveries at Cave Basin, east of Durango, and presumably there was nothing but 'hot air' to the excitement of last spring.

Creede is about the same as usual. Everybody there seemed afraid and stopped shipping ore when the smelters stopped paying for silver, but they are at it again now, just as if nothing had happened, and were grumbling because they did not have cars enough. I saw a number going in as I came out, so no doubt they are all right now. There are about 150 men working in the mines there, and the three properties that are working, the Commodore, Del Monte, and Amethyst, are producing about 1000 tons per month each.——The Creede Mines Co. is getting ready to start the Humphreys mill early in September.——The Equity mine, which is seven or eight miles from Creede, on the extreme north end of the Amethyst vein, is said to have some good ore and to be preparing to build a tram to get it down to the railroad. The Equity company had a stockholders' meeting there, a week or so



ago, which seems to have been a 'knockdown and drag out' affair, from which several of the participants emerged looking the worse for wear.——The fluorspar mine at Wagon Wheel Gap has been equipped with a short tram to get the material down to the valley, and it is expected that it will be started again soon. It has not shipped anything for several months.

At the 'radium' mine near Garo, in South Park county, the owners certainly have some carnotite, but have not done enough work to show whether it amounts to anything or not. The mineral is in two different strata of sandstone (Jura-Trias), which there strikes nearly northwest and dips about 50° to the northeast. They have gone down about 25 ft. and struck water, and have 8 or 10 tons sacked, but have not shipped any ore to date. There is considerable copper in with the carnotite, some specimens showing chalcocite and others only green stains.

Denver, September 1.

IDAHO

Shoshone County

Connection has been made in the Hypotheek mine near Wallace, with the shaft being sunk from surface, and raise being driven from 700 ft. to meet it. The new shaft affords a much better outlet for the workings than the old one. The survey of this difficult work was done by F. Cushing Moore, and the connection was made at 156 ft. from surface and 550 ft. from the 700-ft. level. P. F. Rodgers is manager.——Cross-cutting in the Silver Cable, near Mullan, has opened 30 ft. of 30% zinc ore.——Patrick Burke, managing owner of the Virginia mine, near Wallace, is to increase shipments of zinc ore from the property.——Prospecting and development on smaller properties in the Coeur d'Alenes have not diminished, and the Cedar Creek, Giant, Snowshoe, Sonora, and Liquidator companies are levying assessments.

The Ontario Mining Co. is suing the Stewart Mining Co. for $40,000 as damages for ore alleged to have been knowingly extracted from the Ontario claim. Stewart officials say that the Ontario company is mistaken.——The Morning mine of the Federal company has been shut down, and 250 out of 375 to 400 men will be laid off.

MICHIGAN

Houghton County

Work has been resumed at the Baltic, Champion, and Trimountain mines for two weeks.

MONTANA

Silverbow County

The Butte district has been fairly quiet during the past week, it being under martial law. Several arrests of union agitators were made, and 'Muckie' McDonald was finally captured. The Anaconda company has about 5000 men at work at 11 of its mines, which employ 7105 in normal times, as follows: Original, 605; West Stewart, 500; Anaconda, 730; St. Lawrence, 600; Leonard, 950; Berkeley, 400; Tramway, 900; West Colusa, 800; West Gray Rock, 600; J. I. C., 400; and Moonlight, 620 men. The Anaconda company's Diamond, High Ore, Pennsylvania, Badger State, Poulin, Silver Bow, East Colusa, Mountain View, Mountain Con., Neversweat, and Belmont mines are temporarily closed down. The Butte & Superior and Elm Orlu zinc mines are employing 1000 and 250 men respectively. Over 3300 men have been laid off on account of the copper market.——The boiler-house of the Pilot Butte mine was burned on September 1.

NEVADA

The output of gold, silver, copper, lead, and zinc from Nevada ores sold or treated in 1913, according to V. G. Heikes, of the U. S. Geological Survey, was valued at $37,097,710, against $38,358,732 in 1912. This is a decrease of $1,261,022, or nearly 3.3 per cent.

The total recoverable production of gold from Nevada ore sold or treated in 1913 was 570,589 oz., valued at $11,795,130, a decrease of $1,661,050, or 12.2%, from the production in 1912. Placer mines yielded 14,776 oz., of which 12,600 oz. came from the placers in Nye county. Dry or silicious ores contained 511,402 oz.; copper ores, 39,110 oz; and lead, zinc, and copper-lead ores 5301 oz. The dry or silicious ores yielded over 89% of the entire production of gold. Bullion from gold and silver mills contained 467,550 oz; concentrate, 49,127 oz.; and crude ore shipped to smelters, 37,899 oz. of gold. The mines of Esmeralda county continue to be the largest producers of gold, yielding $5,721,077 in 1913, against $7,014,559 in 1912. Of this amount, the Goldfield district yielded $5,019,419, a decrease of $1,220,328, or nearly 20% less than in 1912. Nye county produced $3,537,799 in gold in 1913, against $3,123,935 in 1912. Mines at Tonopah yielded $2,613,844 in gold, an increase of $389,966, or more than 17%, over 1912. The mines of the Comstock lode produced $853,564 in gold, against $855,494 in 1912. White Pine, Churchill, and Humboldt counties, mentioned in the order of output, each produced more than 15,000 oz. of gold in 1913.

In the past three years the output of silver from Nevada's mines has been steadily increasing, from 13,184,601 oz. in 1911 to 14,369,063 oz. in 1912, and to 16,090,083 oz., valued at $9,718,410, in 1913. Of the 1913 output, 15,245,541 oz., or over 94%, was credited to silicious ores, 313,779 oz. to lead ores, 241,756 oz. to copper ores, and 176,411 oz. to lead-zinc ores. Ores treated at gold and silver mills were credited with 11,-

MINE PRODUCTION OF GOLD, SILVER, LEAD, AND ZINC IN NEVADA, IN 1913, BY COUNTIES

County.	Number of producers.	Ore treated, short tons.	Gold,* fine oz.	Silver,* fine oz.	Copper, pounds.	Lead, pounds.	Zinc (spelter), pounds.	Total value.
Churchill	12	83,901	15,630.15	1,383,257	4,292	162	.....	$1,159,263
Clark	47	36,355	6,970.35	198,922	351,855	6,265,783	14,369,709	1,399,174

Total 1912	704	4,763,965	650,942.71	14,369,063	86,477,494	19,500,100	13,322,988	38,358,732

*Includes placer production.

923,597 oz; concentrate, 2,135,714 oz.; and crude ore sent to smelters, 1,902,528 oz. Nye county produced 11,634,033 oz. in 1913, against 10,210,296 oz. in 1912. The Tonopah district yielded 11,563,457 oz., or 71.8% of the entire silver production of Nevada in 1913. This district yielded 10,144,987 oz. in 1912. The mines on the Comstock lode in Storey county produced 729,972 oz., against 806,853 oz. in 1912, and 618,006 oz. in 1911.

Since July 1, E. Steidle and George W. Riggs of the Bureau of Mines rescue-car have trained 224 men in various mining districts in rescue work and first aid to the injured. There are 41 self-contained oxygen-breathing apparatus at these camps. A total of 5200 people has visited the rescue-car while in Nevada.

ESMERALDA COUNTY

The Goldfield Consolidated company's estimated production for August is as follows: Ore mined, 27,210 tons; gross extraction, $297,500; operating expenses, $168,000; and net realization, $129,500.

The Jumbo Extension mine produced an average of 100 tons of ore daily in August, which was sent to the Goldfield Consolidated mill; also a total of 100 tons of $75 ore to smelters.——Six-inch pipe for the Meiger shaft has arrived, and the pumps are on their way from Dayton, Ohio.——Work on a full scale is to be resumed at the Silver Pick.——Some rich ore has been cut in the Talmage.——In a winze of the old Wheeler lease of the Florence company, 3½ ft. of good ore has been cut.

HUMBOLDT COUNTY

Orders for lumber to build a cyanide plant, and pipe for water supply of the new mill at Rochester have been given, according to John F. Cowan of the Rochester Mines Co. Most of the excavation is finished.——At a depth of 425 ft. from the surface, an 8-ft. vein of $15 ore has been cut in the Codd lease. Lessees in the Big Four are cross-cutting to get this ore.——Since January 1913 the district's output has been $700,000 of silver bullion, of which $600,000 was from the Rochester Mines property.

The new electric pump at the Seven Troughs Coalition mine does splendid work. Ventilation in the mine has been bad, due to recent changes in temperature. A 6-ft. exhaust fan of 236,000 cu. ft. capacity has been ordered for the 1000-ft. level. Profit from the mine in July was $26,000, the present profit being $1000 per day from the 5-stamp mill. The ore averages $200, and tailing $6 to $7 per ton.

NYE COUNTY

Seven mines at Tonopah produced 10,816 tons of ore, valued at $200,100, last week.——The Belmont company will pay 25c. per share or $375,000, on October 1. The new orebody at 900 ft. is 9 ft. wide.——The Extension will pay 7½c. per share, or $70,750, on October 1. Development at 950, 1020, and 1170 ft. is excellent.——The new shoot in the Jim Butler is 4 ft. wide. This Company has filed a reply to the West End company over the apex suit, and generally denies the latter's statement. The West End mill treated an average of 202 tons per day last week, of which 40 tons was from the Halifax.——The Halifax company may build a 100-ton mill.

WHITE PINE COUNTY

Mining claims, railways, dwellings, concentrator, smelting plant, etc., of the Steptoe Valley Smelting & Mining Co. have been transferred to the parent company, the Nevada Consolidated Copper Co. Strictly speaking, this is only a matter of bookkeeping.

UTAH

GRAND COUNTY

According to Samuel McGraw, an old prospector, La Salle Mountain mining district is promising, and about 50 men are employed. Gold-silver-copper ore of good value is being extracted at the Green Mountain mine, owned by R. S. Milbee of Milwaukee.

JUAB COUNTY

A large tonnage of low-grade ore exists in the mines at Tintic, and local milling is expected to make large strides. The Chief Consolidated has started the erection of a 100-ton test plant. This Company's dump contains about 10,000 tons of ore for the new mill.——Some high-grade silver-lead ore has been opened by lessees in the May Day, which extends into Chief Consolidated ground, so the May Day company has secured a lease of the latter's area containing this shoot. A night shift has been added to the Victoria mine.——The manganese deposit of the Homansville Mining Co. has been examined by George Kirby for Eastern people.

SALT LAKE COUNTY

Two feet of sulphide assaying up to 191.6 oz. silver, 7% copper, 5.5% lead, and 40c. gold, is now showing in the west face of the Alta Consolidated. Two faces in the ore-shoot are 65 ft. apart. A carload has been shipped.

SUMMIT COUNTY

Progress in the Snake Creek tunnel in August was 419 ft., for a cross-section of 6½ by 7½ ft., and a ditch 3½ by 4 ft. at one side. The J. A. McIlwee Contracting Co. is doing the work.

TOOELE COUNTY

Mines in the Dry Canyon district, near Stockton, continue to produce ore. The Hidden Treasure, at Gisborn, is shipping 1000 tons of zinc ore per month. D. W. Lynch and Lee Travis are in charge. Prospecting is being done at the Mono, Brooklyn, and Dry Canyon Consolidated.

CANADA

BRITISH COLUMBIA

Work has been restarted at the Josie claims at Rossland, and the output is to be 1500 tons per month.——The Consolidated Mining & Smelting Co. is trying to keep its smelter going, although so many mines are shut down in several districts.——The Standard company has paid 1½c. per share, or $25,000, to its shareholders. As the Trail smelter is not receiving custom ore at present, Standard silver-lead ore is being stored at its mill, and some zinc ore sent to Bartlesville, Oklahoma.

ONTARIO

Business has been resumed at the Standard Stock Exchange at Toronto, and the market shows that Cobalt and Porcupine shares are not in bad condition.

The Dome Lake mill is to start again in October, as development at 180 and 300 ft. has been good. Drills are working in three faces of ore.——Ore production at the Tough-Oakes is being accelerated, both to the mill and smelters.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai province, reports the following results for August:

Stamps working	40
Time, days	26.25
Ore crushed, tons	5,765
Total recovery	$51,000
Operating expenses	22,500
Net earnings	28,500

The Oriental Consolidated output in August was $119,200.

MEXICO

CHIHUAHUA

The Batopilas Mining Co. states that its American staff left El Paso, Texas, for the mine on September 3. John R. Harbottle is general manager. Mexicans have been looking after the property for about a year.

HIDALGO

The Santa Gertrudis has published a report covering the term April 1 to June 30. Owing to the trouble at Vera Cruz the mill only worked to April 21, and treated 22,726 tons of ore yielding $200,327. Total expenses were $174,681, leaving a profit at the mine of $25,646. The interior 'Counter' shaft was sunk 129 ft. to a point 221 ft. below No. 20 level. In the upper part of the mine 1440 ft. of work was done. No noteworthy developments were made. All ore hoisted after the mill closed was stored on the surface, the dump containing 25,000 tons at the end of the quarter. Ore treatment was resumed at a reduced scale on July 6, the dump supplying 25%.

SONORA

The North Sonora Copper Co. has commenced operations on its property in the northern part of the state, 20 miles from Douglas, Arizona. New machinery has been installed, and a development scheme extending over 18 months is planned. The Company's offices are at Douglas, and Dallas, Texas.

Insurgent troops of Governor Maytorena are reported about to attack Cananea.

PERSONAL

J. W. RICHARDS is at Munich.

Address of N. S. KELSEY is wanted.

ROBERT A. KINZIE is in San Francisco.

MORTON WEBBER has returned to New York.

R. E. CRANSTON has returned from Colorado.

FREDERICK COOK, of Joplin, Missouri, was in San Francisco recently.

FRANK LAWRENCE, who has been in Nevada, has returned to San Francisco.

WILLIAM C. RALSTON, president of the United Comstock Pumping Association, visited the Comstock recently.

C. H. MUNRO, who was operated upon recently for appendicitis, is still in the hospital, but is recovering rapidly.

LUIS JACQUESSEN, manager of the Costa Rica mine, Nicaragua, has been ordered to France to join his regiment and has left for Europe.

GEORGE M. ICARD, lately of Grass Valley, California, will return to the Philippine Islands. He was one of the pioneer mining men of the Islands.

H. W. HARDINGE is in Porcupine and will return to New York on September 13. He had just returned from an extended western trip which took him as far as Dawson.

BYRON O. PICKARD has returned to Phoenix, Arizona, from an extensive examination of the properties of the North Sonora Copper Co., for which he is consulting engineer.

R. G. MCCONNELL has been appointed director of the Geological Survey of Canada, succeeding R. W. BROCK, who accepted the position of dean of applied science in the University of British Columbia.

D. L. H. FORBES has been made chief construction engineer for the Chile Exploration Co. at Chuquicamata, Chile. He has been consulting engineer for the Trethewey mine at Cobalt for many years.

EMMET BOYLE has resigned from the Nevada Tax Commission to accept the Democratic nomination for governor. F. N. FLETCHER, of Reno, has been appointed by the governor, T. L. Oddie, to fill the vacancy on the Tax Commission.

E. B. PRESTON celebrated last Wednesday the close of 25 years of service as determinative mineralogist for the California State Mining Bureau. It had been planned to mark the day with a dinner to the staff, but Mr. Preston is unfortunately in the hospital at Santa Rosa. He is one of the best known mining men on the Coast, a Freiberger, a classmate of Louis Janin and others of the famous group of men who brought technology to the mines of the West, and his numerous friends will join in wishing him many years of usefulness.

Obituary

FRANCIS VYVER, a native of London, owner of the Paun mine, Santo Domingo, Nicaragua, died early in July at La Libertad, Nicaragua. Mr. Vyver came to Nicaragua over 28 years ago and has been owner of various properties in the district at one time or another. The property will now be managed by Henry Killig.

HARRY J. HUBBARD, who died of appendicitis July 31 on board the cruiser *California* at Mazatlan, was at the time of his death acting superintendent of the Minas del Tajo. Born in South Dakota in 1882, he graduated from the New Mexico School of Mines and took service at Divisadero in Salvador. After ten years there he joined George W. Tweddy in Sinaloa and remained at his post through all the Mexican troubles. He leaves a wife and two children.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, September 10.

Antimony	15 —15¾
Electrolytic copper	14 —14¼
Pig lead	4.15— 5.10
Quicksilver (flask)	$75
Tin	41 —42½
Spelter	7¾
Zinc dust, 100-kg. zinc-lined cases	20

Quicksilver varies considerably from day to day, but the above quotation may give an idea of the trend of prices, last week being from $75 to $85.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 10.—Copper still has no regular market; lead and spelter are both easier at 3.85 and 5.50c. respectively. Iron ore shipments on the Great Lakes in August were a little above those of July, but in the season to September, the movement is 10,710,000 tons less than the same period of 1913. The U. S. Steel Corporation is again selling ferromanganese, prices being around $85 per ton. The Standard Stock and Mining Exchange of Toronto reopened on August 24, and is holding daily morning sessions from 10 a.m. to 12:30 p.m. Only cash trading is permitted and minimum prices have been adopted by the Exchange Committee. The embargo on export potash from the Netherlands has been temporarily removed, and supplies can now come through from Germany. Imports of these salts into the United States in the past fiscal year were 1,086,243 tons worth $15,160,123.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	....
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	

Prices in New York have been around 53½c., and in London 24d. per ounce, business being restricted in the latter centre. It is reported that the Secretary of the Treasury, W. G. McAdoo, has spoken against the Smoot bill, which passed the Senate, to purchase 15,000,000 oz. He said that the foreign demand is good, so there is no justification for the measure. Under the existing law he will exercise authority to purchase metal. The needs of the Treasury for coinage are well supplied at present.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per pound more. Prices are in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	....
Mch.	14.72	14.11	Sept.	16.23	....
Apr.	15.22	14.19	Oct.	16.31	....
May	15.12	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

The copper market is steadier despite the failure to carry through plans for a pool. This was under discussion for some days, but Washington officials proved deaf to all appeals for help and would not even make a definite statement as to their attitude in event of the pool being formed. This is the more striking in view of the various proposals for government aid to other industries disturbed by the war. The attempt in itself operated beneficial, as the exchange of information among producers steadied those who might have precipitated market trouble, and, considering the dangerous possibilities, the situation is remarkably good. Banks are showing an accommodating disposition, and are not calling loans. While there is still no general or free market for copper, any more than there is for securities, such demand as exists is being supplied at normal prices and if restraint continues to be exercised by producers, it now seems unlikely that prices will go to pieces.

August copper production of several mines is as follows, that for July being in parenthesis: Mammoth, 1,575,000 lb. (1,725,000); Mohawk, 1,110,000 lb. (1,120,000); and Wolverine, 5,300,000 lb. (5,800,000). An official statement regarding the porphyry mines was published on September 4, and showed the following preliminary output for August, curtailment to a 50% basis not being ordered until August 6:

	July.	August.
Utah Copper	13,768,958	8,225,000
Chino	5,087,750	3,139,322
Ray Consolidated	6,008,061	3,300,000
Nevada Consolidated	5,477,313	3,200,000

Exports of copper for the first three days of September were 1265 tons, a decrease of 2289 tons. Prices range from 12.15 to 12.75c. per pound.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Sept. 3	3.85	July 29	3.90
" 4	3.85	Aug. 5	3.85
" 5	3.85	" 12	3.85

June	5.00	4.84	Dec.	5.07	....

There has been a temporary lull in the zinc ore market of the Missouri-Kansas-Oklahoma district, and highest prices are $48 per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Aug. 13	85.00	Aug. 27	80.00
" 20	No quotes	Sept. 3	75.00-85.00
		" 10	75.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	..
Mch.	40.20	39.00	Sept.	39.70	.
Apr.	41.00	38.90	Oct.	39.37	. .
May	40.25	39.00	Nov.	39.40	. .
June	41.00	38.60	Dec.	40.00	. .

Prices are easier in New York, where they are from $70 to $75 per flask.

TIN

Straits tin is quoted in New York at 36c. per pound. With shipments to arrive, September will have enough metal for all requirements.

MINING DECISIONS

Taxation—Mineral Interests

It has been well decided in Minnesota that the owner of land may segregate the mineral estate from the rest of the land, and convey either interest without the other. It follows that where such estate has been so separated, and held by an owner different from the owner of the surface, it may be taxed separately.

Washburn *v.* Gregory County (Minnesota), 147 Northwestern, 706. May 29, 1914.

Adverse Claim—Sufficiency of Title

Where the plaintiff filed an adverse claim against defendant's application for a patent to a mining claim, as in conflict with the plaintiff's claim, and brought suit to support the same, and defendant conceded the overlapping of claims but proved that plaintiff's claim equitably belonged to defendant, a nonsuit was properly granted, although the evidence at the trial might not be sufficient to support defendant's title in its application for patent. The adverse claim was waived by transfer of plaintiff's interests to defendant, and that was the only showing necessary for the latter to make.

Cuenin *v.* Chloride Mining & Prospecting Co. (Colorado), 141 Pacific, 463. June 1, 1914.

Coal Mines—Encroachment on Dividing Line

A deed conveying coal underlying a tract of land described by metes and bounds, giving the grantee "all the usual mining privileges for the removal of the same and every part thereof," does not authorize the grantee to mine coal within five feet of the dividing line between the grantor and the grantee as prohibited by law. A coal mining company is liable for a violation of such a statute by its employees, independent of any knowledge of such violation by its officers. Each separate encroachment within five feet constitutes a separate violation.

Darby *v.* Davis Coal & Coke Co. (West Virginia), 81 Southeastern, 1124. May 5, 1914.

Lodes Within Placers—Degree of Proof

In a suit to quiet title to a placer patented claim against certain lode claimants, the latter alleged as a defense that the placer ground contained known lodes at the time it was patented and that such lodes were excepted from the patent. Held, first that no sufficient discovery of a lode or vein was proved by the evidence to support the alleged lode locations; second, that the lode claimants were concluded as to their claims by a judgment rendered in an adverse suit filed by them prior to the placer patent, wherein the placer claimants were upheld. While such judgment was conclusive only as between the parties, and did not conclude the Government, the latter found the final proof adduced by the placer claimant sufficient to grant the patent. Known lodes, in order to be excluded from the operation of a placer patent covering the ground in which they are situated, must be clearly ascertained to be of such extent as to render the land more valuable on that account and justify their exploitation, and evidence of a vein which might be sufficient to sustain a lode location as against a conflicting placer claim is not sufficient to establish the existence of a known vein or lode within the meaning of the statute. Decree quieting title in placer claimant affirmed.

Mason *v.* Washington-Butte Mining Co. (Montana), 214 Federal, 32. May 4, 1914.

MINERAL STATISTICS

The following data, supplied by the U. S. Geological Survey, covers the year 1913:

Lime production amounted to 3,595,390 tons, valued at $14,648,362, an increase of 65,928 tons and $678,248 in value over 1912.

Mineral-water production was 58,000,000 gal., worth $5,600,000, a decrease of 7 and 15% respectively compared with 1912.

The marketed production of salt in the United States, including Hawaii and Porto Rico, in 1913 reached the record-breaking total of 34,399,298 bbl. of 280 lb. each, or 4,815,902 short tons. The value of the product was $10,132,139. These figures are the greatest yet recorded by the Survey for the salt industry in the United States.

Pennsylvania mined more coal in 1913, both anthracite and bituminous, than in any previous year in the history of the industry, according to E. W. Parker in coöperation with state officials. The production reached the enormous total of 265,306,139 short tons, valued at the mines at $388,220,933. Of this, 91,524,927 tons was anthracite, valued at $195,181,127, and 173,781,217 tons was bituminous or soft coal, valued at $193,039,806. The total tonnage broke the previous record for 1912 by 19,079,053 short tons, or nearly 8%, the proportionate increase being about the same for both anthracite and bituminous. The gain in the value of anthracite, however, was $17,558,501, or about 10%, over 1912, and in bituminous coal $23,669,309, or 14%. The total gain over 1912 was $41,227,810, or nearly 12%. The magnitude of the coal-mining industry in Pennsylvania, as represented by the output of the anthracite and bituminous mines, is probably little realized. The combined production of 265,306,139 short tons in 1913 exceeded by more than 20% the total production of the United States in 1898, only 15 years previous. It exceeded that of any other country in the world, except Great Britain and Germany, and approached within less than 10% of Germany's output. It was nearly five times the production of the Austro-Hungarian empire, nearly six times that of France, nine times that of Russia and Finland, and ten times that of Belgium. It was equal to nearly 20% of the world's total production, and exceeded the combined output of all the countries of the world other than Great Britain, Germany, and the United States. From 1829 to and including 1900, Pennsylvania contributed over 50% of the total coal production of the United States, and the state still produces between 45 and 50% of the total.

There was a decided gain in 1913 in the number of working days made by the employees in Pennsylvania in both the anthracite and bituminous mines, the former making an average of 257 days, compared with 231 days in 1912, and the latter 267 days, compared with 252 days in 1912. The anthracite mines gave employment to 175,745 men and the bituminous mines to 172,196 men

It is pretty generally conceded by those interested in the production of anthracite that the limit of annual production has about been reached and that the yearly output will remain fairly constant until the period of decline begins. Anthracite as a manufacturing fuel has been eliminated, and the increasing use of coke and gas for domestic purposes in the territory supplied by anthracite coal is approximately keeping step with the increase in population. Anthracite mining began between 1790 and 1800, when a small quantity was produced for local consumption. To the close of 1913 the production of anthracite had amounted to 2,184,550,000 long tons, or 2,446,696,010 short tons.

BOOK REVIEWS

MEMORIALS OF HENRY FORBES JULIAN. By Hester Julian. P. 310, portrait, and ill. Published by Charles Griffin & Co. For sale by the *Mining and Scientific Press*. Price $2.50.

When the *Titanic* went down it carried into the sea, among others whom the world could ill spare, one of the foremost authorities on cyanidation—Henry Forbes Julian. His loss has been widely felt among metallurgists and by none more keenly than the *Mining and Scientific Press*, of which he was a special contributor at the time of his death. His personal work has stopped, but he was among the fortunate ones in that he had cultivated the habit of committing to writing the results of his observations and researches, so that the profession has still the benefit of those of his investigations which were completed at the time of his death. Others, unfortunately, are in part at least lost.

There is, however, another side to the work of all those men who make the world move forward, and in that class Julian was well entitled to place. The cold results of scientific experiment are often warmed and vivified by the personality of the experimenter, and influence flows from example and personal contact as well as from formal writing. Julian was a man of strong personality. His life touched many men in many lands, and influence followed contact. So far as such a thing may be done, Mrs. Julian has put into her book Julian as a man—it is his personality she has preserved for his friends. His boyhood at Cork, his early life in his father's works in Lancashire, his technical work in South Africa and Germany, and his travels in Central Africa, Eastern Europe, Italy, Canada, the United States, and Mexico, all these throw interesting side lights upon his career. His comment upon New York, San Francisco, and other of our cities is keen but kindly, and his constant association with the significant men of the times lends an especial interest to what he has to say. One feature of his life that may well be noted by his American confrères was his continued interest in pure science. He traveled to Winnipeg to attend a meeting of the British Association for Advancement of Science and he was a constant contributor to the proceedings of several of the great English scientific societies. We can hardly imagine any American cyanider, equally busy with matters directly touching the commercial phases of his work, interrupting the latter to prepare a paper on physics for the American Association and then traveling to a prairie capital to read it in person. And if any American cyanider of first rank has an intelligent interest in the work of the Geological Society, we have failed to note it. In that they but reflect the attitude of American technical men in general. They are so centred upon their work that they have neither time nor energy for interest in pure science in related lines, whether amateur or professional. We have frequently mentioned the desirability of our engineers broadening out and having 'hobbies,' if that word may be used. It is one of the things the English do better, and it is worth noting that not only did the German *Gold and Silver Scheide-Anstalt* call upon Julian, an Irishman, for advice, but Charles Butters, our American friend who has made for himself so enviable a place among cyanIders, had recourse to the same Irishman for help in preparation of the great patent suit with which his name is associated. Deep scientific insight and broad culture count in technology as in other lines, and that is one of the lessons of Julian's life. That, and the further lesson that life is worth living as one goes along, is one we may take to heart.

Mrs. Julian's chapters are preceded by tributes to Julian from the Rev. J. O. Bevan, who writes of him as a personal friend, and from H. L. Sulman, who, in no less friendly tone, discusses his technical work and associations. It is not necessary to repeat to readers of the *Press* the details of Julian's professional career. His text 'Cyaniding Gold and Silver Ores,' written with Edgar Smart, was not only timely, it is of permanent value; and all because it got down to the fundamental principles underlying the practice of the times. It was that feature which characterized the work of this genial Scotch-Irishman, who crowned a busy career by giving his life that some other might be saved. H. F. B.

THE IRON ORES OF LAKE SUPERIOR. By Benedict Crowell and C. B. Murray. P. 262. Ill., maps, index. Penton Publishing Co. (*Iron Trade Review*), Cleveland, Ohio, 1914. For sale by the *Mining and Scientific Press*. Price $3.50.

Few mining districts of the world have received as much attention as the iron ranges of Minnesota and Wisconsin near Lake Superior, which are of the utmost importance to the American iron industry. The general operations of prospecting, mining, and ore shipments have provided a fund of information for writers in technical journals, mining institute meetings, and books. The volume under review is in its second edition, being prepared by the heads of an organization of 40 experts connected with the iron industry of the district discussed. The chapters cover the following: early history of the region, geology, mineralogy, ore production, dock equipment, classification of ores, beneficiation of ores, methods of analysis, fuel engineering, location and description of mines, and a complete index of mines and ores. Since about 1850 the 10 ranges have produced a total of 626,353,084 tons of iron ore, the Mesabi leading with 313,105,968 tons. In describing mines, the location, character of ore, owner, officials, and shipments are given. The maps are new, and the whole compilation forms interesting and valuable reading.

CHEMICAL REAGENTS. Their purity and tests. Authorized translation of 'Prufung Der Chemischen Reagenzien Auf Reinheit.' Von E. Merck. By Henry Schenck. P. 199. Index. D. Van Nostrand Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price $1.

As its name implies, this work describes the composition and means of testing the purity of reagents used in chemical work. This is the second edition, and is generally similar in treatment to the previous one; but changes have been made, and 36 entirely new subjects have been added. There is also included references of important new contributions on the uses and methods of testing reagent chemicals. Standards to the needs of American chemists have been adopted in several cases. A parenthetical statement is appended to each test, giving in terms of percentage the minimum amount of the impurity which would be recognized by the test, with certain exceptions. The book must be considered useful to all laboratory workers.

MINING WORLD INDEX OF CURRENT LITERATURE. By George E. Sisley. Volume V for first half of 1914. P. 237, with author's and subject index of 29 pages. Mining World Co., Chicago, 1914. For sale by the *Mining and Scientific Press*. Price, $2.

The editor of the *Mining World* goes to a lot of trouble in compiling this volume each half-year, and in spite of the so-called depression throughout the mining world he has abstracted from 345 technical journals, and increased the size of the work by 47 pages compared with the last issue. There is little to add to previous reviews on this regular publication. It covers all of the English-speaking and foreign papers, and will be found useful to editors, libraries, societies, engineers, and those who have use for a bibliography of technical articles. Instead of the 6-point type in former volumes, this one appears in the larger 8-point size, making reading easier.

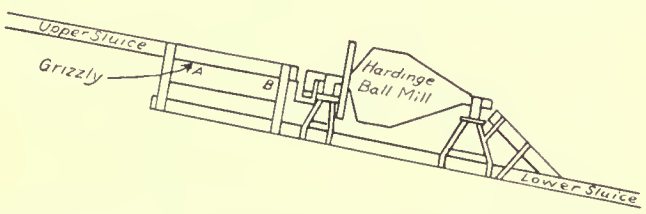
New Machines and Devices

Hardinge Ball-Mills and Cemented Gravel

By V. A. Stout

The usual method of treating cemented gravel from the drift and hydraulic mines of California and the West is to expose the lumps to the disintegrating effects of the weather and to wash it in the sluices. Some few attempts have been made to crush it with light stamps, but without a great deal of success because of the necessity of crushing the hard quartz boulders in the gravel. These boulders having been worn round by the action of the depositing waters, are extremely difficult to crush with stamps and contain no gold. Their reduction merely hinders the disintegration of the gravel, yet there is no means of getting rid of them economically except crushing them along with the lumps of gravel.

With the use of the Hardinge ball-mill for disintegration, this problem seems to be overcome. The hard boulders are not crushed in the mill, but aid the steel balls in their work. Any excess in the mill will take care of itself, and the boulders will be discharged with the disintegrated gravel. In



this way the cemented gravel, when brought to the surface in a drift mine, may be broken up and run through the sluices with an immediate recovery of its gold content. The use of the Hardinge ball-mill in drift mining should present no problems, mechanical or otherwise. In hydraulic mining, due to the quantity of material handled, some problems may arise. These will be dealt with later

While these mills have never been tried as yet in this special field, there are no apparent reasons why they should not be successful. Their large capacity and small horse-power consumption should make them instant favorites among mining men having the problem of cemented gravel to meet. By utilizing the boulders, which cause so much trouble in crushing with stamps, to aid in the disintegration, they overcome a very difficult problem. In this way, too, the cost of wear of the steel balls is greatly reduced. It seems that some steel balls must be used, but it may be discovered in practice that the boulders alone will be all that is required. Because the mills have no screens, the rapid discharge of the disintegrated gravel and the excess of boulders is easily accomplished, and repairs are reduced to a minimum.

In drift mines the use of the ball-mill would be a simple matter. Output is comparatively small and limited in amount. One of the three sizes of the mill with its rated capacity known could be counted on to do the work, but in hydraulic mining there are the problems of capacity and installation to be considered, the last of which seems to be the most difficult. In the accompanying sketch, a possible method is illustrated. The only requisite is a drop in the sluice of five feet at the place of installation. At *A-B* a grizzly with any desired width between the bars is placed. All the fine material would then pass through the grizzly and continue on down the lower sluice, and the pieces of cemented gravel and boulders which could not pass through the grizzly would roll down into the feed-box of the mill or directly into the mill itself. Nothing larger than five inches in diameter could pass through the hollow trunnion of the largest size mill. An attendant might be necessary to pick out the boulders larger than this and to break down with a sledge the larger chunks of cemented gravel. The disintegrated gravel and the excess of boulders would discharge from the mill into the lower sluice. Here the gold content of the gravel would be caught in the riffles and the material discharged in the usual way at the end of the line of sluices.

Rivet Set Retainer

What is claimed to be one of the most novel rivet set retainers is that now put out with the Little David pneumatic riveter, manufactured by the Ingersoll-Rand Co., New York. The retainer consists of a single piece of heavy spring steel, closely wound into a spiral form. One end of this spring fits over the outside of the hammer nozzle and hooks over a projection integral with the nozzle. The other end is wound to a smaller diameter. The device is so effective, it is said to positively prevent the rivet set or piston from being driven out, even when the hammer is run free. There is but a single ground joint between handle and barrel, and these parts are securely held together by two bolts, one on either side of the barrel, which construction eliminates the need of a vise in taking the tool apart for inspection. There are no threaded joints on the barrel. The valve chamber is placed beside and parallel to, instead of in line with the cylinder, for the purpose of obviating the possibility of injury to the valve by the piston, which construction also gives a shorter tool.

Commercial Paragraphs

Busch-Sulzer Bros.-Diesel Engine Co., St. Louis, Mo., has recently published a small attractive bulletin which describes with illustrations the Diesel installations in ice and refrigeration plants in New York and Chicago.

Two Diesel engines for the Burro Mountain Copper Co., Tyrone, New Mexico, have been constructed by Carels Freres, of Ghent, Belgium. These engines will operate at an elevation of 6700 ft., and will develop 1000 hp. each.

Alberger Pump and Condenser Co., New York, has recently published Catalog E, devoted to Alberger centrifugal pumps and steam turbines. The catalog is fully illustrated and contains a large amount of valuable information and tables regarding the construction and operation of turbines and pumps.

The National Tube Co., of Pittsburgh, *Bulletin* 7D deals with regrinding valves. These are made at the same works as 'Kewanee' unions, testing machines for which were tried on 'N. T. C.' valves. Several of these $\frac{1}{4}$-in. valves were taken from stock, and on one testing machine the regrinding valve was opened and closed 3,046,280 times. Construction of the valve is described.

The Wellman-Seaver-Morgan Co., of Cleveland, Ohio, *Circular* No. GP-2 deals with Hughes continuous gas producers. Claims for this machine are elimination of labor in poking, better distribution of coal, better distribution of ash, better quality and more uniform supply of gas, and more gas produced per square foot of producer area. Illustrations in the publication show the producers in detail.

AMONG Belgian firms temporarily suffering from the war is Carels Frères, makers of Diesel engines near Ghent. This concern was just building up a thriving trade in the United States.

SPANISH sources of potash seem likely to become more important, in part due to the temporary withdrawal of German producers from the market. A French syndicate has been drilling near Barcelona, and last year it was announced that irregular but probably important deposits of carnallite, sylvite, kieserite, and rock salt had been found. It is now stated that reserves equal to 200,000,000 tons have been proved and that production may be expected within a year. American production, from Searles Lake, will begin early in 1915.

PHOSPHATE deposits near the Red Sea, according to a recent consular quotation from the *Egyptian Gazette*, have during the past few years assumed importance and the output has increased from 700 tons in 1908 to over 100,000 tons in 1913. Such deposits have been known on both sides of the Nile valley for a number of years, but those on the Red Sea afford the only mines of commercial importance and are responsible for practically the whole output. A movement is said to be under way at the present time for the manufacture of super-phosphates at Alexandria.

COUNTRY smelter management receives consideration in this issue by Mr. Herbert Lang, who through years of experience is enabled to present the managers' viewpoint in an instructive manner. In former years local smelters were common; but, as our readers are aware, changed conditions have brought about the concentration of smelting in the larger centres, bringing to an end the activities of many of the isolated plants which were once so numerous. With modern methods of construction and power equipment it seems possible that the smaller works have a new chance for life and usefulness. In one respect at least local smelters have the advantage over their great competitors. The fume difficulty, which weighs more heavily upon the large smelters, by reason of their usual location in settled districts, must favor the local concerns, in their isolated and sterile situations. Unless the fume question be settled effectively, the tendency of the future may be to conduct smelting operations at the place of production.

BUTTE copper mining companies have issued a general notice to the effect that they will no longer recognize either the Western Federation or the Butte Mine Workers Union. While existing wages, hours, and conditions of labor will be maintained, the companies refuse to compel employees to join either union or to permit representatives of either organization to visit the mines to inspect cards, buttons, or other evidences of membership. In effect this opens the mines of Butte to non-union labor, and it is easy to foresee that in time the absurd prices and conditions foisted upon the community by unions in the other trades will be seriously modified. The miner at Butte has carried the other workers on his back till the burden has become like that of Sindbad. As we pointed out recently, the operators at Butte have been wonderfully patient with their men. We believe that in the end both men and companies will be the better for the change now made.

NOW that the tumult and shouting of various primary elections have died down, it is possible to survey the field at leisure. In California, Mr. W. C. Ralston and Mr. C. M. Belshaw, both well and favorably known among mining men, after a gallant fight for nomination for governor on the Republican ticket, went down to defeat. In Nevada, on the other hand, Mr. Emmett Boyle was chosen as Democratic candidate for the office mentioned. In Iowa, Mr. Charles R. Keyes, among those mentioned some weeks ago, decided not to be a formal candidate in the Democratic primaries. Among nominations to minor offices may be mentioned that of Mr. J. Nelson Nevius for senator in the Thirty-sixth California district. We are glad to see mining men taking part with other citizens in political affairs. While in Colorado, Montana, and other Western States there have always been a few men from the mines in the legislature, they have seldom been engineers. Usually, with some honorable exceptions, they have been 'hired men,' legal or otherwise. We must confess to a feeling that the country has suffered from too general a disposition to let 'some lawyer do it,' when it came to spending time in the routine work of making and enforcing laws. To the young lawyer, whose practice has not yet become a burden to him, experience in the legislature is valuable, and in view of the disposition of others, including mining men, to shirk, it is not surprising that the lawyers have predominated in the public service. If, however, best results are to be achieved,

the legislature should be made in fact as well as in name an assemblage of representative men in all lines of industry. Our sympathies therefore are with the mining men, without regard to party, who have made or are making races in politics. It is a public service that deserves support.

AMERICAN DREDGES FOR FOREIGN COUNTRIES

The article on dredge construction in Portuguese East Africa, by Mr. Charles Janin, which appeared in the *Mining and Scientific Press* of August 1, has awakened considerable interest among those concerned in dredge construction. Mr. Janin called attention to the fact that the American dredge was slowly but surely invading the foreign field, that nearly all the American dredge builders were successfully represented, and that there was a good future abroad for the American-built dredge.

While the first modern California-type dredge in operation in a foreign country was built by the New York Engineering Company in Eastern Siberia in 1911, an earlier type of the California gold dredge was shipped to Siberia in 1900 by the Bucyrus Company. This dredge was equipped with 5-foot buckets. A similar Bucyrus dredge was shipped about the same time to the Magdalena river in Colombia. The old Risdon company, which was bought out by the Union Iron Works in 1910, sent dredges to Mexico, Tierra del Fuego, and West Africa about 1903, and to the Philippine Islands a little later. The New York Engineering Company also shipped some earlier dredges, one to Brazil and another to Colombia. Among the first American-built dredges were some for New Zealand built by an iron works in New York about 1900.

Of the modern California-type dredge shipped abroad, the Bucyrus Company, in addition to the one described in our issue of August 1, sent one to Burma about 1910. This dredge, however, was not erected. The New York Engineering Company built a 5-foot dredge for the Guamos company in the Philippine Islands in 1913. The Yuba Construction Company built the Pato dredge for Colombia, which started in January 1913, a 5-foot dredge for the Malaguit Gold Dredging Company in the Philippine Islands in 1914, and supplied the machinery for converting the Pokrovsky scow of the Orsk company in Siberia to a three-foot close-connected bucket dredge. The Marion Steam Shovel Company has supplied the machinery for a 7-foot dredge for the Ural district in Siberia this year.

The Union Construction Company designed a dredge for the recovery of tin in Portugal. This dredge was built by Fraser & Chalmers of London, and is the first American-type dredge built for tin recovery in a foreign country. It is perhaps the work of this dredge, and that built several years earlier by the Union Construction Company for Cape York district, Alaska, that has encouraged American dredge companies to investigate the foreign tinfields with an idea of supplying dredges. Several of the larger companies have sent or are contemplating sending representatives to the Far East, and a fact of considerable interest is that Mr. E. A. Peacock, who is interested in tin dredging operations in the Malay States, when in California a few weeks ago was so impressed by the progress made in dredge construction and the work done by the California dredge, that he canceled, by cable, orders which he had previously given to dredge builders in Australia and is having plans drawn here for a modern California-type dredge especially designed for tin recovery. Bids have been submitted by at least two companies, and the dredge will undoubtedly be built in the near future.

Facts such as this should waken the American dredge builder to the opportunity knocking at his door; it is our pleasure to help show him the path, and his to make good as he has done in the past, and can do in the future.

A CALIFORNIA MINE OPERATORS ASSOCIATION

California operators are invited to meet at the rooms of the Engineers' Club, Hotel Sutter, San Francisco, next Monday afternoon at 2:30 to join in forming a mine operators' association. This movement is being started by Mr. Albert Burch, who, as manager for the Goldfield Consolidated Mines Company, has had many opportunities to see the substantial benefits that have accrued to mine operators in Nevada from membership in their local association. It is not too much to say that thousands of dollars have been saved to the operators since the Nevada association was formed, and there are equal opportunities for savings in California.

Membership in the Nevada association is restricted to "persons, co-partnerships, and corporations" engaged in mining "as operators of approved standing," and the purposes are broadly stated as being "to subserve, promote, and protect the interests of operators engaged in the prosecution of the metal mining industry in this state, and in that behalf to secure betterment in all branches of the industry; also to promote the health, safety, and welfare of miners and employees engaged therein, and to promote harmonious relations between employer and employees." In practice the Nevada association is a business organization, as, in fact, are all the really successful associations of operators. It maintains a secretary who acts for the executive committee as a bureau of information and also as a central purchasing agent. Through the data collected by this central agency the operators were able materially to affect the revision of the taxing system, and by buying in large lots those materials that every mine needs, large savings have been made.

California operators have been too slow in getting together. The increased cost of living affects mining companies as well as workmen, and it is time to look at these matters from the business standpoint. Mr. Burch has

the promised coöperation of Mr. Seeley Mudd, Mr. J. C. Hutchinson, Mr. G. W. Metcalfe, Mr. W. F. Kett, and others equally closely identified with the best in California mining, and we strongly urge all operators in the state to attend the meeting, and affiliate with the new organization.

LABORATORY STUDY OF SECONDARY ENRICHMENT

Investigation of the phenomena of secondary enrichment, especially in copper deposits, is now as much the thing among geologists as the development of foreign trade is among merchants. The sudden crescendo of interest in a topic which has long been under discussion develops much the same advantages and disadvantages in each case. It brings to bear additional effort, with a corresponding increase in the results attained, and it also incites many people to join in the chorus by repeating what is old or disproved, or by making statements which are unsubstantiated by valid evidence or fundamental principles. The danger of the latter, in the case of secondary enrichment, is lessened because most of the workers are presumably trained investigators, but it is also increased by the fact that this is a peculiarly difficult field of investigation. The changes which take place in the enrichment of a mineral or group of minerals are obviously chemical and physical, and it might be at once assumed that a physical chemist is the proper person for unraveling them. But the possible changes to which a group of minerals may be subjected are almost infinite in number, and many or most of them would throw little or no light on the actual phenomena observed in the field study of the ore deposits. Investigation must be selective, therefore, and here the danger enters. Few geologists who are experienced field observers have a sufficient grasp of physical chemistry intelligently to direct such investigations, while the number of chemists who are experienced field geologists is almost zero. There is thus a lack of coördination of the knowledge necessary for a right treatment of the subject.

It is worth while to recall the genesis of present ideas on this topic. Only a short time ago, historically, geologists were storming the breastworks of religious folklore in order to establish the conclusion that the Universe was brought to its present condition by the action of natural forces. One line of attack followed another: the recognition that sedimentary deposits are formed through the washing away of surface rocks brought out the fact that the mineral composition of the deposits thus formed is not the same as those from which they are derived, and the alteration of one mineral into another was thus clearly established. Increase of observations multiplied the number of instances in which one mineral was known to alter into another, but it is only recently that any exact knowledge of how such changes take place has been available. Any lack of ability to explain these changes was generally excused on the ground that it is impossible to reproduce natural conditions of temperature, pressure, and length of time involved. Fortunate experiments in which the results found in nature were actually attained in the laboratory have shown that the difficulty is not in reproducing conditions, but in knowing which are the important and which the negligible ones. Simply reproducing in the laboratory the results of natural processes is much like setting a tuning fork in vibration by crashing down with both hands on the keyboard of a piano. One mineral is not converted into another, unfortunately, by such simple and direct processes as those by which a live pig is converted into hams and bacon. In order to understand the complex changes involved, it is necessary to unravel them and study them separately in detail.

Most mineral substances have, from the chemist's standpoint, discouragingly wide variations in chemical composition, and a more exact systematic knowledge of them than we now possess is highly desirable. Not only are they variable in composition, but they are exceedingly impure, and the chemist who knows the effect of the presence or absence of a few tenths of a per cent of carbon in iron is appalled at the possibilities disclosed by a careful analysis of such comparatively simple minerals at chalcopyrite, sphalerite, galena, and so on. FeS_2 sometimes crystallizes in the isometric system and sometimes in the orthorhombic, showing at the same time considerable differences in other characters. It is only recently that we have learned why, and the fact indicates the great desirability of exact knowledge of the temperature range within which the common minerals are stable. The dissociation temperatures and pressures of these minerals should be known. More light on these points will doubtless indicate the necessity for further data and in time a fund of knowledge will be built up that will make easy the solution of what now appear as exceedingly difficult problems.

It is in such fields of work as that above outlined that the necessity for institutions devoted to pure scientific research, such as the Geophysical Laboratory of the Carnegie Institution at Washington, is made evident. Work of this character is not and can not be done in laboratories of the colleges and technical schools. Professors are unable to devote their time to work which is so unproductive of visible result, and few of them indeed are fitted to perform it. It is totally beyond the powers of their students, and it is not too much to characterize many of the contributions to the knowledge of this subject which have come from college laboratories as being rather obfuscations of knowledge. Sweeping the heavens with a field-glass is not likely to add astronomical knowledge, and soaking powdered minerals in solutions of various salts is not apt to prove more efficacious in advancing our knowledge of mineral chemistry. This is peculiarly a field in which advance must be left to a comparatively few trained men who have both the desire and the mental and physical equipment to carry on the work.

As War Looks in London*

By T. A. RICKARD

Ross Hoffmann and his brother Jack arrived yesterday from St. Petersburg. They went by train to Archangel, and there chartered a small boat for Vardo, just across the Finnish border in Norway, whence they took the regular steamer to Bergen, from there to Newcastle, and so to London. They suffered no privation.

W. J. Chalmers, the original Chalmers, of Fraser & Chalmers, now a young man of 65, alert and keen-witted as ever, has arrived from Carlsbad. He was 16 days on the way and was arrested 49 times—after that he ceased to count. His wife had been taking the cure at Carlsbad. They came away with a party of friends in three motor-cars through Pilsen, Budweis (and other places that beer has made famous), Salzburg, Innsbruck, Feldkirch, and then across the Rhine into Switzerland, avoiding German territory and fearing to enter Italy lest that country might also be at war. They did not know of the Franco-Prussian or German-British declarations of war until a week after the events, and only figured on the Austro-Servian conflict. Chalmers was wise enough to leave every scrap of writing at Carlsbad, to have the passports of his party *visé* by the Hoffmeister and Governor, and to procure Austrian, German, Swiss, and French currency—and lots of it. As he says, by keeping your temper, by being courteous, and by lavish tipping (in gold) you can get most anywhere. He did. At Zurich they found a crowd of refugees. He speaks highly of the Swiss banks, which advanced £8 twice per week on letters of credit and raised it subsequently to £12; these local banks arranged to honor drafts in payment of hotel bills; and generally relieved the financial complications in a most intelligent manner. He speaks bitterly, I am sorry to say, of the Swiss agents of Thos. Cook & Son; these closed their doors, refused to make refunds on tickets that they had issued, and declined even to honor the cheeks of their own firm. This looks like a stupid blunder—to put it mildly. Mr. Chalmers—bubbling over with health, bright and cherry—says that the Americans in Germany and Austria will be subject to great hardship. At health resorts like Carlsbad, there are hundreds of poor people that have come there to take the cure and are without money, ill, frightened, distraught. He considers—and I agree—that the Americans in England are having a picnic and that your relief committees ought to attend promptly to the care of those of your people in our enemy's country.

August 20.

There are persistent rumors, accompanied by circumstantial statements, that train-loads of Russians are arriving in Scotland and crossing England on their way to France. These allied troops are said to have come by sea from Archangel, around Norway, to the Scottish ports. Gilman Brown says that some of the Russian members of the staff at Kyshtim and Tanalyk were ordered not to go to their usual centre of mobilization, but to prepare for special duty, on account of their knowledge of English. Then Curle tells me that there is a big lumber trade on the river Dwina, debouching into the White Sea at Archangel, and that the numerous saw-mills there can furnish thousands of soldiers. Besides, there is plenty of shipping, some of it captured German vessels, at Archangel, available for army transport.

August 28.

That rumor about the Russians is confirmed. J. F. Erdlets, who, as mining engineer, has been in Russia, tells me that he saw a batallion of them at King's Cross station. H. W. L. Way, who used to be in Colorado, saw them passing in trainloads through Cambridge a few days ago. So it appears that they have traversed England on the way to France. British troops from India are arriving at Marseilles. I hope they will arrive in time to face the great attack that the Germans are expected to make in celebration of the anniversary of Sedan, on September 2, the day after tomorrow.

American friends, like Heinrich Ries and W. J. Chalmers, have confessed how useful an American accent proved to them in their escape from Germany and Austria. At these times we realize that we do not speak the English language in quite the same way, although we write it much alike. It is better to be a Philadelphian than a Bostonian just now at Dresden or Carlsbad. On the other hand, it goes hard with those here who speak with an obvious German accent, as is the case with friends of mine that I know to be not only naturalized, but loyal, British. One man and his family were unable to get porters to help them with their luggage at a railway station, on account of their hostile pronunciation.

August 31.

Will Irwin, of San Francisco, the correspondent for *Collier's Weekly*, has passed through London. He was at the battle of Mons and happened to be at Louvain when it was destroyed. According to him, some boy-scouts did attack the Germans, killing three officers, and that is why the old city was sacked. It appears also that whenever a shot was fired from any house, the Germans killed everybody in it—men, women, and children—as he came to know by going later to the house where he had lodged. This exasperated the Belgians so as to drive the boys to retaliate. It makes the story more horrible, but it does not excuse the enemy's barbarity. Frederick Palmer, I hear, is the only correspondent accredited with the allied forces: he was chosen to represent the American press.

September 2.

*In this series of war letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies, but he will endeavor to be as impartial as he may.

REPUBLIC, WASHINGTON, LOOKING DOWN CLARK AVENUE. REPUBLIC AND NORTH WASHINGTON MILLS IN THE DISTANCE.

Mining and Milling at Republic, Washington

By E. C. MORSE

For the past 15 years Republic has been best known to mining men by reason of its meteoric history, its 'ups and downs,' its spectacular periods of production, and its sudden declines. The district deserves more attention from mining men of means than it has been receiving lately. There has been a good deal of money earned in the past few years by lessees. The operating companies which succeeded them were generally struggling concerns, operating with the same equipment employed by the lessees and little if any more capital and generally with a large burden of indebtedness representing the purchase price of the property upon an inflated valuation. As fast as any good ore was found it was mined out, and shipped to a smelter or mill, so that few of the properties have any ore blocked out, except such as was too low in grade to yield a profit, at the time the mining was done. A brief description of conditions prevailing at the principal mines around Republic may not be out of place here.

Long Mineralized Zone

The mineralized zone in which the orebodies occur is about five miles long and extends from the Mountain Lion and Tom Thumb region on the north to the Republic and Jim Blaine on the south. The aggregate yield to date of these ore-shoots has been more than $5,000,000. A large part of it has come from high-grade ore in relatively small ore-shoots which have been mined by lessees and small companies, the production being distributed over the entire zone.

The Mountain Lion is one of the most northerly properties in the district. It was an extensive shipper for a number of years. It has a wide vein which was fairly exhausted down to the adit level, at a depth of about 300 ft. Sinking has been done for several hundred feet below the adit and good ore of at least milling grade has been developed, though it has been but partly blocked out. The Mountain Lion ore is the most uniform in grade of any in the district and the pay-shoots are said to be large. One of the early mills was built on this property. It contains a good steam-power plant, twenty 1250-lb. stamps, four Huntington mills, and an early type of MacArthur Forrest cyanide plant. It was not adapted to the ore, only recovering about 50% of the gold. The Mountain Lion is owned by the McLarren estate at Ottawa, Canada, and has been idle for the past six years and may not resume operations until the cheap electric power, which appears now to be in sight, comes into the district.

The Tom Thumb is a group of claims owned by a Walla Walla company which has good mining equipment and is supposed to have a wide vein of ore averaging perhaps $7 or $8 per ton, but none rich enough to ship to smelters. This property is also idle. The Knob Hill mine has had a good ore-shoot which has produced a large quantity of high-grade ore and has paid the purchase price of the mine. The property is at present paying for a systematic development campaign. High-grade ore is shipped to smelters and low-grade ore to the San Poil mill. Sinking is also in progress.

Eureka Gulch

In Eureka gulch for about a mile and a half there are two separate vein systems which parallel either side of the gulch. On the west side is the San Poil group, the Ben Hur mine, the Trade Dollar, and the Gold Dollar claims. For the most part this is not such a strong vein as the main or 'mother' vein of the east side, which is generally called the Surprise vein and extends through Quilp, Surprise, Hope Group, Lone Pine, Pearl, Little Cove, Knob Hill, and Mud Lake claims.

The Ben Hur mine is being operated by the Ben Hur Leasing Co. and is down about 600 ft. Three years ago this mine was supposed to have been exhausted, but it has shipped approximately 100 tons per day to the smelter during the past year, besides sending low-grade ore to the San Poil mill.

The San Poil mine made a good showing during the

SAN POIL MINE AND MILL. LITTLE COVE SHAFT IN THE FOREGROUND. KNOB HILL AND BEN HUR MINES IN THE DISTANCE.

first year's operation of the mill. The past year's work on the lower level has not been satisfactory, though promising ore has been reported recently. Considerable custom milling has been done.

The Republic Mines Corporation, one of the most important groups in the district, owns the Surprise, Lone Pine, and Pearl claims. The property extends for three-quarters of a mile along the Surprise vein, but owing to the fact that much of it was on relatively low ground and not very well known to early lessees, only one ore-shoot has been opened, though there are many good indications of others.

The Surprise mine, a relatively short shoot, has been worked for a depth of 700 ft. and in two years time produced more than a million and a half in shipping ore. This has paid for the mine and a number of dividends, and also contributed largely to the building of the North Washington mill. On the 700-ft. level the ore is richer than elsewhere and the shoot is longer.

An adverse court decision in an injunction proceeding brought by the Quilp company, in the initial stages of an apex suit, seriously crippled the Company and a factional quarrel which followed completely wrecked it. At present this property is about to be sold under the hammer.

The Lone Pine's Good Showing

The Republic Mines Corporation has not only the Surprise mine, with whatever claim it may have to the disputed ground and the Surprise vein, but also a number of cross-veins on the Lone Pine and Pearl claims, which have received more attention than the main vein. On the Lone Pine, lessees and early operators in search of high-grade ore, exposed a large ore-shoot about 500 ft. long for a depth of several hundred feet. In places this was more than 30 ft. wide and of good milling ore. A $7 average is claimed. Under the direction of the trustee the Pine workings were recently pumped out and systematically sampled, with gratifying results.

One of the cross-veins just mentioned is in the Insurgent fraction and the Last Chance claim. A leasing company mined the streak of high-grade ore in the Insurgent to a depth of 700 ft. and left ore ranging from $8 to $10 for a considerable width. This has exposed a good face of high-grade ore on the end-line of the Last Chance claim 700 ft. deep.

The Hope company has the old Blacktail properties, which contain a network of veins and apparently a large tonnage of milling ore. The Company also owns considerable ground along the Surprise vein which has received little attention so far, together with a good mill-site. The Quilp mine, adjoining the Surprise on the main vein, has shipped large quantities of ore to the smelter and is supposed to have a large tonnage of milling ore. The Quilp claims ownership to the disputed ground which contains a large part of the so-called Surprise ore-shoot.

Rathfon Reduction Co.

A persistent campaign of exploration work at the Republic mine is being pushed by the Rathfon Reduction Co., a group of experienced mine and mill operators headed by Messrs. Rathfon, Bewley, and Bradley, who control the property. They are developing a large body of low-grade ore which they think will be profitable when cheap power is provided and the property is equipped with a suitable mill. They also have good sized shoots of better grade ore, and frequently ship carloads that range from $100 to $150 per ton, to help pay for development. There are a number of promising prospects around the Republic and between there and the Quilp, but there is not much activity there at present.

Transportation facilities are good. The district is served by two railroads, the Great Northern and the Spokane & British Columbia. One or the other and often both of them reach all the important mines. As milling progress has reduced milling costs, so has there been a reduction in smelting charges, which are little more than half what they were three years ago. This is partly due to the increased demand for siliceous ores at the Granby smelter at Grand Forks, the Trail smelter, and the British Columbia Copper Co.'s smelter at Greenwood, British Columbia.

Milling Republic Ores

Four factors interfered with the success of the half dozen earlier mills, besides the lack of a continuous ore supply of suitable grade: the high power cost, which is

THE BEN HUR MINE. KNOB HILL, LITTLE COVE, PEARL, AND LONE PINE MINES IN THE DISTANCE.

still a drawback; the hard quartz, some ribs being as high as seven in the scale of hardness; necessity of pulverizing the ore till 90% or more passed a 200-mesh screen to release the gold; and suitable grinders, agitators, and filters were not developed and consequently not used in the earlier mills.

The power cost with steam, using coal at $6.60 per ton, is the largest item of cost, making nearly half of the total working cost in the San Poil mill. Shields and McKane of Spokane recently applied for a franchise for transmission of electric power from the Bannington Falls wires at the Canadian border through Ferry county to Republic. If this project is successful, it will reduce mining and milling costs $1 per ton on 100-ton plants, which would greatly increase the available tonnage in all the mines.

The San Poil Mill

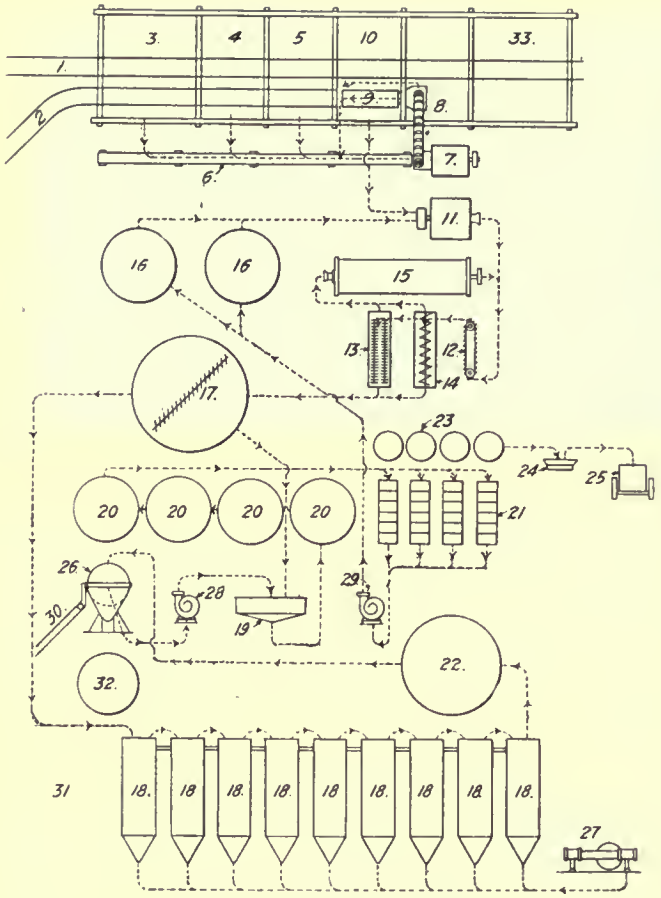
The San Poil mill has been in operation nearly two years and treats 100 tons per day. In the matter of tonnage, much depends on the kind of ore that happens to be treated. For example, it is as easy to crush 120 tons of Ben Hur ore, as it is to crush 85 tons of the hardest Lone Pine ore. These ores represent the two extremes in grinding costs. In a general way, extractions range from 88 to 95% of gold and silver on mixed Republic ores. Much depends on the grade of the ore being treated, for their is little difference in tailing assay whether the ore be high or low grade For the most part it has been customary to grind until 94% of the material passed 200 mesh. Mixed Republic ores usually contain 5 oz. silver to 1 oz. of gold. About 30% of the gold content is combined with silver sulphides, so that a considerable portion of silver must be dissolved to render a high extraction of gold possible. This necessitates the use of a fairly strong cyanide solution. Experience has caused the adoption of about a 7-lb. per ton KCN strong solution and 5-lb. KCN working solution. Cyanide is added at the strong solution tanks at the head of the ball-mills and pebble tube-mills. Lime is added to keep up the required alkalinity. From 1 to 2 lb. cyanide is consumed per ton of ore treated, generally about 1½ lb. About ⅔ lb. lead acetate is added per ton of ore and the zinc shaving consumption is about one pound per ton of ore. Under these conditions milling costs in April, including office, assaying, and corporation expenses, were given as $3.33 per ton and in May, $3.35 with a short month's run. Cast white iron liners with ribs are used in the tube-mill. The flow-sheet is so near the standard practice that only portions of it require special mention.

The Crushing and Grinding Plant

Three machines with the necessary launders, conveying, elevating, and classifying arrangements constitute the crushing and grinding plant. The equipment consists of one Williams chain hammer mill, one 6 by 6-ft. ball tube-mill of Traylor Engineering Co.'s manufacture, and one 5 by 22-ft. pebble mill supplied by the Allis-Chalmers Co. A loss in the running time of the ball tube-mill has been experienced owing to the use of brittle white iron linings in place of the standard chrome or manganese steel linings. In other respects the methods and results are well up to the average of ball-mill and pebble-mill work.

Ore is delivered to the bins from the San Poil mine by cable tram which passes over the top of the bins, or, if it be custom ore, by bottom dump cars from a Great Northern railway siding which also passes over the bins. From these bins the crude mine run ore is fed by hand to a belt-conveyor which transmits it to a Williams chain hammer mill. Pieces up to a foot in diameter can be fed into the mill. This crusher breaks everything to pass a ⅜-in grizzly.

A bucket-elevator lifts the crushed ore to a trommel, which is used if it is desired to crush finer than one-quarter mesh, the oversize being returned to the mill. The trommel is rarely used at present. From the elevator the ore drops through a sampler to a storage bin from which it is fed into the ball tube-mill, which grinds the ore to pass 20 mesh. From the ball-mill it goes to a bucket-elevator which delivers it to a Dorr and an Akins classifier arranged in tandem, the finished product going to the first Dorr thickener and the oversize to the pebble-mill and through it to the elevator and back to the classifier, and so on until 94% is reduced to 200 mesh. The only feature in the arrangement not often met with is the Williams chain hammer mill.



FLOW-SHEET OF SAN POIL MILL.

The accompanying flow-sheet will give a clear idea of the arrangement and operation of the mill.

The Hammer Mill

The hammer mill is a near relative of the Quinner crusher, so successfully used in dry placers in northern Mexico. The present hammer mill has been in successful operation for more than a year, and it is so satisfactory in all respects that it deserves more than passing mention. The first hammer mill placed in the San Poil mill gave trouble because of too light a frame construction, and the Williams company replaced it with the present machine, which has overcome these objections. An inspection of the illustration will enable one to understand the principle upon which the machine operates.

There are fourteen 40-lb. hammers fastened to a central shaft with chains which whirl around at the rate of 300 r.p.m. Outside of this, but covered by a metal housing, is a squirrel-cage grizzly trommel built up of 1 by 2-in. bars on edge and spaced according to the fineness to which it is desired to crush the ore. This cage revolves in the same direction as the hammers, but at a speed of only 60 r.p.m. The ore is fed to the machine through a hopper. The whirling hammers break it up until it is fine enough to fall through the grizzly spaces of the trommel. Good work has been done with the machine with spaces as close as $\frac{3}{16}$ in., when the ore was dry, but where the ore is wet, it is not advisable to set the machine to crush finer than ⅜ inch.

On hard Republic quartz crushing to ⅜ in. the machine frequently reaches a capacity of 20 tons per hour; its average capacity is about 15 tons per hour. The horse-power consumed depends on the rate of feed and speed of crushing. About 30 hp. is the average. Ordinarily 6 hours running time is sufficient to supply the mill for 24 hours. But this time is divided over several periods, for the storage bin is only 16 ft. deep. Two shifts are employed on the hammer mill. The hammer mill-man attends to repairs, looks after conveyor, elevator, trommel, and assists with feeder to ball-mill.

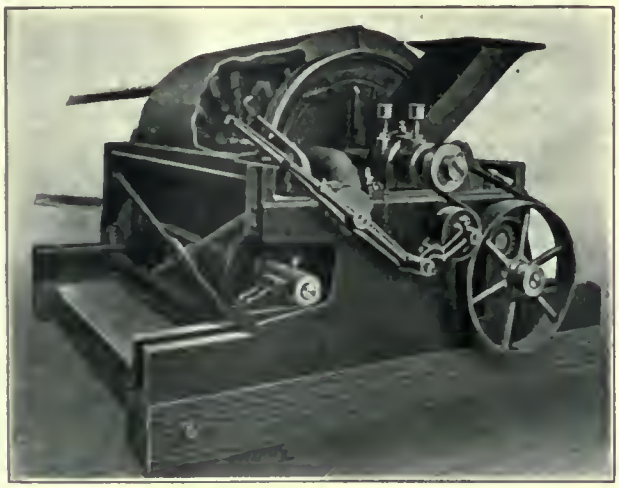
Costs of operating the hammer mill using white iron hammers, soft steel chains, tool steel grizzly bars, under power conditions prevailing at Republic per ton of ore crushed are approximately as follows:

	Cents.
Power for crushing, elevating, and conveying	4.6
Labor for crushing, elevating, and conveying	8.0
Repairs for crushing, elevating, and conveying	8.0
Hammers and chains	4.5
Total	25.1

Repair cost is the only objectionable item. The principal part of this is represented by renewal of grizzly bars. A set lasts about four months. This item has been between 6 and 7 cents per ton where tool steel has been used. Manganese steel bars are being tried at present and it is hoped that better results will be obtained in this respect. Much of the hammer consumption is due to breakage of white iron hammers rather than to their wearing out. It has been shown that there would be a saving of about 25% by the use of manganese or forged steel hammers, but no arrangement has yet been made for a regular supply, so the white and

gray iron hammers cast at local foundries are still being used. The cost of operating compares well with any combination of machines which cost several times as much money. It does good work on a more economical scale in crushing to ½, ¾, or 1-in. size and is suited as a preliminary crusher to prepare material for Chilean mills, Hardinge mills, ball or tube-mills, stamps or rolls, or for making jig feed for concentrating plants.

The hammer mill has often been compared with stamps by its critics. To say that the hammer mill is equal to the stamp as a hard-rock crusher under any conditions, is saying a good deal, for there is nothing that equals stamps, in simplicity, reliability, ease of adjustment, or repair, and they are also possessed of that desirable quality of being as nearly 'foolproof' as a



SKELETON VIEW OF WILLIAMS CRUSHER.

crushing machine can be. However, where it is only desired to crush to ¼ or ½-in. mesh and follow with Chilean or Hardinge mills, after the manner of the Nevada Hills or Commonwealth mills, the hammer mill is a good substitute for stamps. Without discussing the matter further, I will say that the hammer mill approaches the stamp in efficiency when it is only desired to crush to ⅜ or ½-in. size. One hammer mill can be depended on to do the same volume of work as a rock-crusher and fifteen 1250-lb. stamps. It costs about the same installed as one 5-stamp battery, so it will appeal to concerns of modest means or those whose operations are of a relatively temporary character.

The mill was originally designed and built by contract for $45,000, including ore-bins, building, shafting, power plant, transmission of power, light plant, Dorr thickener, Dorr classifier, Oliver filter, nine small Pachuca vats, tanks, and a crushing plant consisting of one hammer mill, a set of rolls, and a Gates 5 by 22-ft. tube-mill, everything on concrete foundations, but not including railway, water supply, tramway, or refinery.

For $10,000 more money the Hammond Manufacturing Co., which had the contract, offered to substitute 30 stamps of 1000 lb. each for the hammer mill and rolls, but cash had to be provided for the stamps, while the other machinery could be bought largely on time. While in the end the San Poil company developed a good system of preliminary crushing, it would have been ahead at least $25,000 if stamps had been taken even at an added cost of $10,000, for that amount would have been saved in remodeling, alterations, experimental work, and lost time.

With the present rapid progress in metallurgy and the wonderful development of mechanical appliances of every description, it is not strange if any design of mill grows old fashioned in some respects even while it is being built. For instance, it would now be a mistake to design a mill so that elevators have to be used in the classifier and tube-mill circuit, in view of experience in the Tonopah Belmont and Commonwealth mills. It would also be a mistake not to use counter current or replacement washes with additional Dorr thickeners between the sets of agitators at least on silver ores, as applied in the Buckhorn mill. After a trial of both, I like a number of small Pachuca agitators in series better than a few large ones, but I believe the Dorr agitator is better than either.

Zinc dust precipitation as applied by the Merrill Metallurgical Co. is undoubtedly the right thing for large plants, but zinc shaving is satisfactory for small mills, particularly where considerable silver is present in the ore. I would not now attempt to use anything but a Dorr machine for 200-mesh classifying. The Oliver filter seems to be especially well suited to Republic conditions.

Some metallurgists hold that by using concentrators in the tube-mill circuit, returning the concentrate to the mill until ground fine enough to float off in the tailing, would enable one to make the extraction at 100-mesh and thus largely reduce grinding costs. Laboratory tests indicate that this is true of some of the ores. The San Poil company never felt able to try this in a commercial way.

Future of the District

It is generally agreed by all familiar with conditions, that with cheap power, a mill of economic size, and mining in larger way it is possible to make a profit on ore assaying more than $4 per ton in the larger veins and over $5 per ton in the smaller veins around Republic. It is also known that in the aggregate there is a lot of ore present. There is not enough blocked out in any of the mines to justify fancy selling prices. There is considerable prospective ore in a good many of them. Unless it be true of the Republic Mines Corporation there is no one property with enough ore in sight to justify a very large reduction plant. A consolidation of the more important properties could probably be financed by an exploration and milling company, and this would solve the problem. Or a leasing and milling company safeguarded in such a manner as to insure the continuation of development, after the manner of the Ben Hur Leasing Co., only in a larger way, using either of the existing mills as a nucleus to be altered or enlarged as circumstances warranted, would probably handle the situation.

Management of a Country Smelter

By HERBERT LANG

It is privately thought by persons of experience in this line that the management of a smelting establishment, especially one devoted to custom work is the most difficult and trying of all human occupations. Some have held, but perhaps too extravagantly, that to carry on such work demands more brains, experience, and technical skill than any other pursuit. One needs not accept this, but there is no doubt that smelter management of the right kind requires high mental qualities, along with a great fund of experience and skill. These qualifications are not always present among managers, but I have no doubt that, taken as a whole, the class of managers and practical adepts would stand a rigid comparison with the best financial and technical lights throughout the world. Excellence in metallurgical pursuits, as in most others, can be attained only by those gifted with brains, aided by the experience of many years in the various subordinate branches of metallurgic art. It is a good—even an indispensable—thing for the manager to have had personal experience in most of the trades and professions directly connected with his craft. He must be a good business man; he ought to be a good technical man whenever, as happens in small plants, conditions prevent him from calling to his aid an ample staff of highly skilled subordinates who can relieve him of the technical part of his load. The manager who is *au fait* with all departments has a right to be a little vain-glorious, and, it may be added, he is none too common.

Selection of a Crew

In no department is the manager's wisdom more to the point than in the selection of the crew, for so much depends on the character and aptness of the people associated in the undertaking. The shrewdest judgment must be employed in choosing from among the miscellaneous crowd of job-seeking aspirants fit individuals to carry on the work. It might be thought by those who casually visit some great metallurgical establishment and observe the kind of men largely employed there, that muscle rather than brains was the desideratum, but this is a mistake. The 'bone-head' contingent may largely predominate, it is true, but this, to a certain extent, is a necessity of the case.

It must not be supposed that effort is lacking to substitute mechanical for human means in doing the routine work of the smelter, for unlimited brains and ingenuity are constantly being expended in such directions. Increasingly in this, as in all other industrial occupations, machinery is taking the place of muscle, but there still remain many necessary tasks which, to the chagrin of the manager, must be performed by raw human strength. This is regrettable most of all to the designer, whose ideal is always an establishment wherein the total of the work would be performed merely by the touching of buttons and the pulling of levers.

The Ore Supply

The local smelter obtains its supply of ore either by purchase from the surrounding mines or by working ore deposits on its own account. Ordinarily both methods are followed, since it will be understood that the purchase and treatment of outside material is the less reliable source; in short, it is a less dependable and usually less lucrative business. It is easy to make contracts on more or less advantageous terms with mine-owners, but difficulties arise when the sellers are required to produce and deliver particular kinds of ore, such as may be demanded by the exigencies of the smelting operation. The convenience of the smelter man is not much regarded by the miner, nor does the economical work of the mine harmonize with that of the furnace. It is advisable, consequently, to go outside of the contracting mines, and by working suitable properties to furnish acceptable ores in quantities to suit the furnace requirements.

It is needful to take at least the preliminary steps toward securing a proper ore supply before beginning construction, or in fact before news of the project is reported. The operator should go into the chosen field before the inhabitants have wind of the undertaking, and proceed in the quietest way to make contracts for the largest deliveries of ore, covering the longest possible period, securing thus both mines and ore whenever feasible. The miners, awaiting the advent of some such works, or very likely almost unaware of their appropriateness or utility in the district, are generally favorable or even enthusiastic toward such a proposition; but there are others who, from motives of their own, oppose, or greet it with coldness. After the project has taken root, however, their sentiments in many cases take a new turn, and those who have not supported it primarily are apt to take the ground that as long as the new concern exists it will need their product and will ultimately be compelled to pay a high price therefor.

This somewhat selfish view should be foreseen, and a sufficient amount of ore secured in advance, so that the backward mines may be left out of account if desired. Such men often overreach themselves by waiting too long and trying to drive too hard a bargain. I have seen, and I was not sorry to see, cases where valuable mines were left unworked during the whole time of the smelter's activities in the camp, and left so after its work was finished and the establishment dismantled, because the mine-owners insisted on terms which the ore purchasers thought it unwise to grant. Decidedly, it will not do for some mines of a district to lie idle

while the others are being exhausted when they should be worked together for fluxing, for upon the constitution of one or two deposits may depend the availability of all the others.

Fluxing the Ore

This consideration leads us to a discussion of the whole matter of fluxing, so important to the welfare not of the smelter alone, but of the whole district. This is aside from the main topic, but it is appropriate to say that in the practical smelter's mind a flux is a barren material put in to enable the charge to run properly to serve some function connected with the formation of metal or matte. Everyone knows how rare it is to find ores which perform all these functions alone; therefore, it is necessary to add in almost all cases some otherwise valueless material, which in some cases may be iron bearing, in another lime bearing, and in another silicious. Some ferrous sulphide, which is not usually regarded as a flux, may be necessary occasionally or regularly, for example. Fluxing ores are those which fill these requirements while carrying valuable minerals.

As the object is to avoid as far as possible the addition of barren matter to the charge which would increase the cost and the loss in slag, the proper ores are sought with avidity, and their procurement becomes a matter of vital moment. The requirements differ in different districts. In a region blessed (or cursed) with a superfluity of metalliferous quartz, the proper fluxes are limestone and iron; in a country characteristically ferruginous—in plainer language, where iron chiefly prevails—the fluxing material must be silica, with some limestone. Should lime prevail, we must provide sufficient quartz and iron, even by importing them from a distance. By 'iron' I mean iron-bearing ores in some convenient form. Thus, in some cases the flux would be silica; in others, iron or lime, or both. Thus we enlarge somewhat upon the ordinary conception of a flux, which includes simply the basic matters; that is to say, those that combine with silica. Fluxing ores are valuable to the smelting project in proportion to their scarcity. Thus a single vein of gold-bearing quartz in a district prevailingly ferruginous or calcareous, being indispensable in slag formation, might save the project from failure. Likewise a single, and perhaps restricted, deposit of some iron mineral in a region of quartzose ores might be equally valuable. These considerations are introduced to show how important it is to a new smelting project to take account of all the ore deposits in the district, and viewing them in the large way, to settle upon the proper policy as to their procurement.

Selecting the Ores

The experienced operator, carefully traversing the district for the purpose, and considering the character of the ore of those veins which are to be worked, will be able to fix definitely upon the kind of fluxing material wanted, and will know where it is to be found. Thorough inquiry into the matter will reveal to him the existing sources of such materials, and will settle the question of their composition, fitness, and quantity. Besides the run-of-mine ores which always form the staple of such operations, there are frequently other sources of material valuable to the smelter, such as the concentrate from gold-milling, the tailing left after chlorination of the same, the accumulation of scrap iron about old millsites, and the old and abandoned mills themselves. Idle chlorination, amalgamation, and lixiviation plants often yield valuable materials, such as the brickwork of their furnaces and the woodwork of their vats, which will invariably be found to have absorbed the metals. There may be metal also in the dust collected in their flues. All such sources of profit should be looked carefully into by the intent metallurgist or manager whose perspicacity and business skill will have full play during the early days of the new institution.

Sampling and Buying Ores

The means by which the value and chemical composition of ores are ascertained are well understood, but deserve consideration in connection with local smelters, since they are occasionally modified there to suit peculiar conditions. Machine sampling, so much in vogue at large and well established works nowadays, is not entirely in place in the mining camps, partly on account of the suspicion existing among the comparatively unsophisticated inhabitants, and also because of the lack of the necessary apparatus. But as the miners come to understand the unerring action of machinery, in contrast with the older methods of hand labor, it appeals more and more to them. This, however, implies education and the lapse of time. Machine sampling is not only the most economical and expeditious, but it is also the most accurate, all things considered, of all the means by which the value of an ore can be ascertained. In consequence, however, of ignorant suspicion so frequently encountered, it becomes necessary for the smelter to adopt at times hand methods, and to use much tact and discretion in ore dealings, giving way as far as may be to whims and prejudices, and taking much pains to avoid harmful antagonism. It is sometimes necessary to take samples of ore in very inconvenient localities. I have felt obliged on occasion to send men to some isolated mine or prospect situated, perhaps, on a steep hillside, where absolutely no conveniences could be found, to draw the samples from dumps of ore which the seller would not allow to be removed to the smelter before being paid in full. Such are extreme cases, no doubt, but well illustrative of the obstinacy and stupidity of some miners. In such a situation, I cut down the heap by hand, broke the larger lumps, and after a great deal of labor obtained samples sufficiently accurate to base the price on, and by prompt settlement did a great deal to remove the miner's prejudice, thus leading eventually to considerable profitable business.

Nearly all beginners in mining are prejudiced and permeated with suspicions which arise from the stories current in the camps as to the dishonest methods of ore dealers, which, by the way, are an undeserved aspersion on the character of an uncommonly honorable fraternity. The Mexicans are the worst in their treatment of ore buyers, but even their prejudices may be removed in time by tact and patience and by compliance to the greatest possible extent with the whims and notions which have persisted for centuries. Ore buying in their country demands a knowledge of local conditions and practices, and especially of the laws, which are somewhat severe upon the 'tenderfoot' buyer. The experienced ore purchaser in that country or this, is in a position largely to benefit his company by the exercise of business sense and by his knowledge of the fluxing powers of different materials, although in the latter respect he will be directed by the metallurgical staff.

He should be wide awake to every detail of his employment, and should overlook no opportunity to secure even the smallest job lot of ore, concentrate, or other suitable paying material to be had. In the purchase of small lots of rich ore quite disproportionally large profits are frequently made. But unfortunately these batches are too frequently the result of 'high-grading' operations in distant mines, and their receipt causes a good deal of embarrassment to a management desirous of clean dealings and of securing the best bargains possible. The manager may have well grounded fears that his concern may become a sort of 'fence' for the receipt of stolen goods, for no one outside the business can have more than a faint idea of the extent to which these thieving operations are conducted. But these small transactions, however profitable they may be, are of little consequence to the actual running of the furnaces, since the total weight of such small lots is hardly comparable to that of the run-of-mine ores which are the main dependence.

Ore Buyers and Contracts

It was formerly customary for the principal custom smelters of the West to keep their ore buyers in the field, bidding for ores in competition with each other; but since the consolidation of the smelting companies this practice has ceased, and one or two traveling men do all the work which once occupied a large number. Longer contracts are now made, in some cases the whole output of a productive mine being taken for terms of as much as ten years. It will be readily understood that if the larger properties of a district have been thus tied up, the chances for independent establishments getting a foothold will be pretty small, and that local plants will find little opportunity against such competition. However, as I have indicated, the policy of owning or at least controlling the ore supply will relieve them measurably from competition and outside oppression. The difference in the cost of freighting to the outside plant and to the local one will be the measure of the profit of the latter, for the difference is not small as a rule. It must not be assumed, however, that it is all profit, since the cost of reduction is almost invariably greater at the local plant, added to which the smelted product usually has to be freighted to a distant refinery at comparatively higher rates than those which are paid for shipments of raw ore. It is not to be forgotten that the operations in the local works are few and simple. Generally they are confined to sampling, roasting, and smelting; or, more frequently still, to the single process of smelting, leaving the product in a comparatively crude form to be shipped away and subsequently converted into commercial form by other processes.

Relations of Smelter to Producer

The attitude of ore sellers toward the buyers, while ordinarily friendly enough, is not always so. In mining camps there is heard a great deal about the tyranny of the smelters and their disposition to freeze out the miner, the most of which is unadulterated bosh. All such allegations could be dismissed without remark, simply remembering that both parties are apt to behave precisely as business men should, each being intent on making all the profit possible in the transaction. I consider that the smelter is entitled to all he can make, taking square issue with those who appear to hold that he should take all the risks and pay as near to 100% of the contents of the ore as the miners might wish. I know of no reason in justice or equity why a smelting establishment should be run on an eleemosynary basis, notwithstanding the common notion that they should exist solely to 'develop the country' and 'give the miners a chance.' The only sound reason for the existence of a smelting works is money-making.

One Source of Friction

Although miners rail at the prices exacted for treating their ores—prices, by the way, which are wonderfully low if we consider the nature of the work—they frequently say severe and even less justifiable things reflecting on professional honesty. To understand this, we should put ourselves in the place of the mine or prospect owner. It is natural for him, looking most probably for capital to purchase or work his property, to put up the best possible front, and to exaggerate its richness. No one likes to confess his mine a failure, so when it is put to the crucial test of a trial shipment of the ore, the owner's feelings are much wrought up. If at such a time the ore is found to assay lower than had been claimed, it is only natural, though not by any means excusable, to put forward claims that the smelter has robbed the owner. Such allegations are not readily forgotten, and too often form the subject of everyday conversation in the camps. That the most of such allegations are false, there is no doubt: but much may be forgiven to the man who has to undergo the harrowing realization of his property's worthlessness.

Production of Radium in America

By CHARLES H. VOIL

The production of radium in the United States from ores occurring in this country, and the proposed legislation whereby the Bureau of Mines would undertake to produce radium have been the cause of a great deal of comment on these subjects during the present year. Many of the statements which have been given the widest circulation and have enjoyed a general credence have been made with a view to accelerating the pending legislation, and the truth frequently has been overlooked in the effort to make a stronger appeal to the sympathy of the public.

A Radium Famine?

The statement coming from Washington recently to the effect that America is to suffer from a radium famine because of the war in Europe cutting off that source of radium well illustrates how little the truth is considered. As a matter of fact, far more radium is now being produced in the United States than in all the rest of the world. In view of this little understood fact it may be of interest to give some facts with regard to the radium production in the United States. Experimental work on radium production is now being carried but by the Bureau of Mines in coöperation with the National Radium Institute, a corporation which will ultimately receive the radium so produced, and numerous experimental plants are engaged with the problem of extracting radium from the low-grade ores available, but, so far as I know, only two companies have actually produced radium in the United States. These are the Standard Chemical Co., of Pittsburgh, Pennsylvania, and the Radium Company of America, of Sellersville, Pennsylvania. Of the quantity of radium produced by the latter concern I have no authentic information and the quantity is probably small.

The Standard Chemical Co. is the largest producer of radium in the world. The output of radium salts produced by this country is three times greater than the aggregate output of all the rest of the radium producers in the world.

Present Production

The radium produced from January 1, 1914, to September 1, 1914, in the Radium Research Laboratory of the Standard Chemical Co. contained 14,000 milligrams (14 grams equal one half ounce avoirdupois) of pure crystalline radium bromide ($RaBr_2 \cdot 2H_2O$). This corresponds to 7500 milligrams of actual radium element in the radium preparations, all of which consisted of 50 to 75% pure radium salts. Radium sulphate, bromide, and chloride are the salts most commonly used.

The production at present is at the rate of 2240 milligrams of pure radium bromide per month (1200 milligrams of pure radium element), and before the present European war cut off a large part of the market for radium, making necessary a corresponding curtailment of production, the output of radium by the Standard Chemical Co. in the year 1914 was conservatively estimated at between 22,400 and 24,200 milligrams of pure radium bromide, corresponding to from 12 to 13 grams of radium element. Because of the war the output for 1914 will be somewhat less, although as has been stated, the production to September 1 already amounts to 7.5 grams of radium element. In 1915 it is expected that the output will average 1500 milligrams of radium element per month, making a total of 18 grams of radium element for the year. This is equivalent to 33,600 milli-

THE RESULT OF CONCENTRATING 300 TONS OF CARNOTITE ORE, 500 TONS OF CHEMICALS, NOT INCLUDING WATER; 1764 MILLIGRAMS OF RADIUM BROMIDE, ACTUAL SIZE.

grams of pure radium bromide, a quantity equal to one-half the world's total present accumulation of radium.

The Standard Chemical Co. produces radium from carnotite, a uranium vanadate from Colorado and Utah. The Company owns many claims in these carnotite areas and mines its own ores. At present from six to ten tons of ore must be mined in order to secure one ton of shipping ore. After mining and sorting, the ore is packed by burro to the foot of the trails, and from there it is hauled 60 miles by wagon to the nearest rail station, from whence it is sent to the Company's reduction mill at Canonsburg, Pennsylvania, where the ore is treated. After the radium has been extracted from the ore, together with the barium, the radium-barium salt is sent to the Radium Research Laboratory in Pittsburgh, Pennsylvania, where it is subjected to a long process of concentration, the radium finally being separated in the form of 60 to 75% pure radium salt.

To produce radium from carnotite involves the treat-

ment of enormous quantities of ore, because the greater amount of carnotite ore is of a very low grade. Ore containing 1 to 1.5% of uranium oxide (U_3O_8) can be worked, although 2% ore is more desirable. The world's future supply of radium will probably come from these carnotite deposits in Colorado and Utah—and since the ore is mainly low grade it will be necessary to work up material containing 1% or less of uranium oxide. To produce a gram of radium element in the form of pure radium salt requires the working up of 400 to 900 tons of ore, and the treatment involves the use of almost twice this weight of chemicals—exclusive of water—and about 150 days are required for the production of the finished radium ready for delivery.

Prices and Grade

From this standpoint of cost of production the present price of radium is exceedingly low. At present (September 1, 1914) the market price is $120 to $160 per milligram of radium element contained in a preparation. Barring a few sales by the Curies and Giesel in the earliest days of radium production—where the selling price bore no relation to the cost of production—the price for radium in the past few years has been between $187 and $280 per *supposed* milligram of radium element.

Much of the radium sold earlier than 1912 and some in the market since, has been found to have been greatly overrated as regards purity. Now that the international radium standard has been prepared, all preparations are standardized by gamma ray comparison on this basis, and purchasers should demand a guarantee of the actual radium element content of preparations of a certificate of measurement by the Bureau of Standards in order to assure themselves of what they are getting.

In spite of the great difficulty in preparing radium, and the really small quantity of it in an available form, a great deal of work has been carried out since 1903 on the therapeutic applications of the radium rays, and it is now conceded that radium has a definite place in therapy. It has been used very successfully in the treatment of certain forms of cancer and in the treatment of a great many non-malignant skin growths. In spite of its price radium is even finding a considerable use in internal medicine.

To produce radium from such ores as the carnotites of Colorado and Utah requires first, that a sufficient supply of ore be assured, since the handling of the ore necessitates the investment of much capital in expensive equipment. Because the Standard Chemical Co. has assured itself of a supply of ore adequate to its needs for some years to come it has been unjustly accused of seeking a monopoly in this field. The present price of radium is called exorbitant, in spite of its being the lowest in years, and in spite of the fact that radium salts are now guaranteed to contain radium—whereas in the past they were supposed to contain this element—and usually were greatly overrated as regards content of radium element, and in spite of the fact that radium is now being made from a low-grade ore which is much more expensive to treat.

The war abroad will cause no radium famine in America—and if the radium industry is to grow—if radium is to be produced from American ore in America for Americans as the Secretary of the Interior and the Directory of the Bureau of Mines have been urging—more can be accomplished now by encouraging private capital to continue in this field than by discouraging it by such legislation as is now contemplated, looking towards the production of radium by the Bureau of Mines. Government production of anything is notoriously slow and expensive, and it is my opinion that the worst thing that could happen to the radium industry, and the science of radium therapy would be the governmental production of radium in America. The delusion of cheap radium would delay the acquisition of adequate supplies of radium by hospitals, and radium treatment would continue a luxury for the few. Experimentation would be sadly hampered, and by cutting off the market in the United States, producers would be forced to sell their radium abroad, or go out of business.

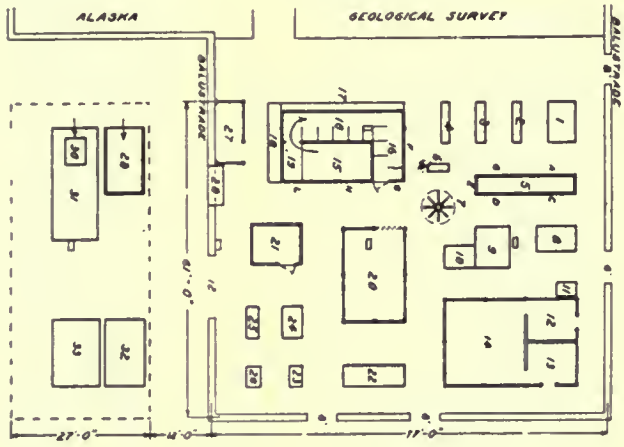
Handling and Use of Fuse

Have careful tests of the burning rate of the fuse made periodically, especially whenever a new brand is purchased. Different makes and brands of fuse burn at greatly varying rates, and a miner accustomed to a slow-burning fuse will perhaps not realize the necessity of cutting the faster-burning fuse longer so that he may have time to reach a place of safety before the detonation takes place. There are several causes that may increase greatly the rate of burning of the same brand of fuse, and there have been cases where an injured fuse burned almost instantaneously. Chief among the causes are abrasion, blows, or too great pressure. Therefore, in addition to informing the miner as to the normal burning rate of the fuse, see that fuse is in good condition when taken into the heading and that it is handled properly after it gets there.

See that the fuse is properly stored, for a large percentage of the accidents from misfires are traceable to fuse that has been damaged in storage. Never store fuse near boilers, steam pipes, or other sources of heat where the temperature is apt to be high. Exposure to heat causes a marked retardation in the burning rate. Never store fuse in a cold place. Cold fuse is dangerous, because cold often causes fuse to crack when being handled, so that misfires result. Keep fuse dry. It is difficult to dry out a powder train that has become damp, and when the fuse burns, the dampness will be driven ahead of the fire in the form of steam, so that, even if it does not accumulate in sufficient quantity to quench the fire in the fuse, enough of it may be driven into the detonator to prevent that from igniting and thus cause a misfire. Always provide a dry place with an even temperature for the storage of fuse.—*Miners' Circular, Bureau of Mines.*

Bureau of Mines Exhibit at the Exposition

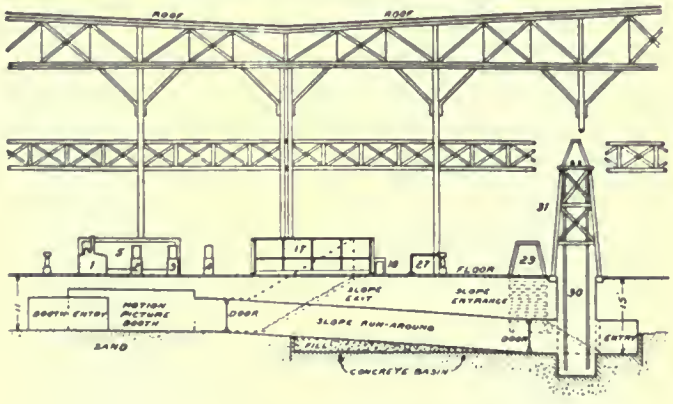
The United States Bureau of Mines is planning a comprehensive exhibit at the Panama-Pacific International Exhibition. In arranging the exhibit, the Bureau has had in mind, not only the value of interesting those engaged in the various mining and metallurgical industries, but also the education of the general public to a better knowledge of the magnitude of these industries, and to the efforts which are honestly being made by miners and mine operators, with the assistance of the Bureau, looking toward a more safe conduct of mining, and a more efficient utilization of the products of the mines after they are won from the earth.



PROPOSED PLAN OF EXHIBITS.

LEGEND, FLOOR EXHIBITS.

1. Fuel efficiency.
2 and 3. Coke and by-products.
4. Coal analysis.
5. Smoke production.
6. Explosives.
7. Explosives.
8. Model change house.
9. Metallurgy.
10. Metallurgy.
11. Duplex stereomotorgraph.
12, 13, and 14. Hospital receiving room, ward room, operating room.
15. Mine exit.
16. Radium booth.
17. Radium products.
18. Radium ores.
19. Passway.
20. First aid.
21. Smoke room.
22. Rescue apparatus.
23. Lamp testing box.
24. Testing apparatus.
25. Lamp rack.
26. Duplex stereomotorgraph.
27. Office.
28. Publications.
29. Mine entrance.
30. Shaft.
31. Head-frame.
32. Fan.
33. Hoist.



ELEVATION, LOOKING EAST.

The exhibit is situated in the Palace of Mines and Metallurgy. An automatic duplex projecting machine will continuously show lantern slides illustrative of the activities of the Bureau, and simultaneously give descriptions of the lantern slides. Nearby will be shown the layout of a model hospital, including a receiving room, ward room, and operating room, fully equipped for demonstration by the U. S. Marine Hospital Service; also a model of a change and wash-house, another welfare feature which is being installed at modern mining and metallurgical operations. A plan of an ideal mining town will be shown.

First-aid demonstrations will be given frequently. An air of reality will be lent to the demonstration by the removal of apparently injured men from the exhibition mine beneath the building, by helmet and rescue crews. A complete display of rescue apparatus and safety lamps will be given in a glass smoke-room. Tests of safety lamps will be made, showing their tendency, under unfavorable conditions, to ignite explosive gas, and also showing methods of testing for explosive gas by means of their caps. An exhibit of the physical and chemical characteristics and constituents of explosives is being arranged.

Visitors going through the exhibition mine will regain the surface through the radium booth, in which actual radium emanations will be shown. Surrounding this booth there will be complete exhibits of various radium-bearing ores and of radium products. The metallurgy of various products will be shown by a comprehensive exhibit.

The opportunity for increased efficiency in the use of fuels will be demonstrated by a device showing the proportionate amounts of fuels which go to make up the various losses incident to consumption, in comparison with that which ultimately goes to useful purposes. Typical analyses of coal from the various fields will be shown by models and samples, as will also the yield of coke and by-products obtained by various coking processes. It is expected to show smoke-preventing and smoke-producing methods of stoking by means of an ingenious motion-picture device.

An officer of the Bureau will give his whole attention to visitors. Copies of the Bureau's publications will be available for free distribution to visitors who may be particularly interested.

This exhibit, in connection with the exhibition mine immediately beneath the Bureau's space, should be interesting and instructive to those engaged in the mining industry and to the general public.

VALUE of the mineral production of the United States is over $2,500,000,000 per annum.

Electric Hoists in the Cleveland-Cliffs Mines

By F. E. STANFORD

*Two types of electric hoists have been developed, each occupying its own field. These are the direct current hoist, operated by the 'Ilgner' system, and the induction motor driven hoist. Wherever the desired product of a mine can be hoisted in three-ton loads at a speed of 1000 ft. per minute or less, induction motors directly geared to the hoist are used. Where a greater product is desired the 'Ilgner' system is used. The experience which we have had in the past few years in the practical operation of electrically driven hoists indicates that the conclusions arrived at are entirely sound and that the load and speed indicated is the proper division as between the use of the two different types of hoisting apparatus. With a larger generating station, larger induction hoist motors could be used. In designing hoists for electric drive, it is desirable that they shall be made for as low a rope speed as possible, rather increasing the weight of the live load as necessary, than going to high speeds with light loads. At present only one 'Ilgner' set is in service. This is a Westinghouse set having a 350-hp. induction motor, a 400-kw. 600-volt direct current generator, a 150-kw. 200-volt direct current generator, a 25-kw. 200-volt exciter, and a 25,000-lb. flywheel mounted on one shaft. The direct current generators are connected directly to a 500-hp. 600 r.p.m. first-motion hoist motor for ore skips, and to a 200-hp. 250 r.p.m. motor with helical gears for the cage or man hoist. The flywheel set has an automatic slip regulator, which by an automatic changing of the resistance in the rotor of the induction motor, gives a variation of speed from 550 to 720 r.p.m., depending upon the load. The armatures of the generators and hoist motors are connected directly by 1,000,000-cm. cables without intermediate circuit-breakers, the motors having constant excitation in the fields, and the control being by varying the field of the generators. This gives a very reliable service, as the flywheel will usually have sufficient stored energy to complete any trip, even if there is an interruption in the current supply. The ore hoist is designed for a 90-second cycle under a 1000-ft. hoist and gives a maximum hoisting speed at full load of 1500 ft. per minute.

Test of Flywheel Set

Depth of shaft (sump to dump)	900 ft. vertical
Net weight of load per trip	9290 lb.
Weight of skip (self-dumping)	5330 lb.
Size of rope, 1¼ in. diam	2.2 lb. per ft.
Hoisting	balanced
Size and shape of drum	cylindrical, 8 ft. by 66 in. wide
Weight of drum and shaft (from drawing)	31,650 lb.
Radius of gyration of drum	3.86 ft.
Total revolutions of drum	35.8

There are connected the following induction-hoist motors:

Chase mine, one 200-hp. double-reduction geared hoist with direct control—Allis-Chalmers.

Morris mine, two 400-hp. double-reduction geared hoist with remote control—one General Electric and one Westinghouse.

Lloyd mine, two 400-hp. double-reduction geared hoist with remote control—General Electric.

Cliffs shaft mine, one 500-hp. double-reduction geared double-drum hoist with friction, remote control—General Electric.

Salisbury mine, one 400-hp. single-helical geared double-drum hoist, with friction, remote control—General Electric.

Princeton mine, one 200-hp. double-reduction geared hoist with direct control—General Electric.

Princeton mine, one 75-hp. double-reduction geared hoist with direct control—Westinghouse.

Austin mine, one 150-hp. double-reduction geared hoist with direct control—Westinghouse.

Gwinn mine, two 400-hp. double-reduction geared hoist with remote control—one General Electric and one Westinghouse.

Gardner mine, one 400-hp. single-helical geared hoist with remote control—General Electric.

Mackinaw mine, one 400-hp. single-helical geared hoist with remote control—General Electric.

Athens mine, one 400-hp. single-helical geared hoist with remote control—General Electric.

South Jackson mine, one 75-hp. double-helical geared hoist with remote control—Westinghouse.

With the smaller motors, the direct control was found, with an oil-immersed primary reversing drum, to be fairly satisfactory when the control is properly designed. The secondary contacts must be of ample capacity and with positive 'snap' into position. The primary reversing contacts should have a quick and positive make-and-break before the secondaries come in. The oil tanks should be so designed that oil will not be thrown out, and the leads must be brought out where they may be readily inspected. Ample barriers should be placed between phase leads, because with the accurate spotting sometimes necessary with a hoist a quick make-and-break will likely cause surges which may cause a flash-over.

For the control of large hoist motors, solenoid-operated contactors are used exclusively. The only primary switches found, that are entirely reliable, have an air brake. While this causes an annoying flash and noise, it is good evidence to the operator that the switch is working properly.

The line-contact points must not make a 'butt' contact, but should have wiping contact. This is because the contacts may possibly burn together and fail to open when the controller is thrown off. This form of contact is also best for secondaries for the same reason. Just such a burning together of contacts nearly caused a serious and fatal accident with an old form of contactor which we had in service; the motor failed to stop at surface when the control was off. The single-phase type of control operation seems to be simpler than dividing the contactor closing coils into three phase.

Hoist motors must have very rugged and substantial frames, as the pounding of gears and frequent starts and stops is very severe. Phase leads and coils should be rigidly supported to prevent vibration or distortion under excess current. Adjustable bearing brackets are desirable. The usual excuse that these things are non essential should not be passed, because when a hoist is once in service it must be ready at all times for service and frequently the lives of men are dependent upon its reliability. The banding of the rotor should be extra strong because of the possibility of overspeed. We require that lowering shall be with the current on to prevent overspeed.

An electric safety overwind has been developed which has been found very reliable. It is similar to most others which have been brought out, but has been somewhat simplified. The operation is as follows:

A contact-making device is attached to the indicator on the hoist with one contact made about 100 ft. below the collar of the shaft. This is controlled by a foot switch operated by the brakeman; if the hoist is under control and the switch is opened it does not operate. The final contact closing is positive and is at danger point. As soon as closed it actuates the circuit-opening relay which trips the low-voltage release, and opens the motor lines. This permits the holding coil to open and operates the air brake. The trip may also be operated by an overspeed governor placed on the end of the motor shaft. If the current supply fails for any reason, the brake immediately sets. It will be observed that this device does not in any sense relieve the brakeman of his responsibility, and while it is in a certain sense automatic in its operation, the intermediate stop, which is under the control of the brakeman, necessitates that he shall have his mind centred upon the work in hand at all times. This practice seems to be more desirable than to introduce a device which would entirely remove 'the personal element.'

THE IMPORTATION OF ICHTHYOL, a peculiar asphaltic material found in Australia, which finds application, after appripriate chemical treatment, as a very important medicament, has been, along with many other products, cut off by the war. The raw material comes from a fossiliferous deposit near Seefeld, in the Austrian Tyrol. It is carefully selected and subjected to dry distillation. The distillate thus obtained is then sulphonated and subsequently neutralized with ammonia. The use of this material has greatly increased in the past few years, and it has proved very beneficial. Almost immediately following the beginning of the war its price doubled, going to over 60 cents an ounce. Already, however, a firm in St. Louis has a material on the market which has been favorably recommended as an efficient substitute closely resembling ichthyol itself.

Mining in the Tavoy District, Lower Burma

By E. MAXWELL-LEFROY

The town of Tavoy, on the river of the same name and 32 miles from the mouth, is the head town of its district, which is a part of the Tennassarim division of Lower Burma. In addition to being the official headquarters, it is also a business centre for the import of goods, has numerous stores for the supply of mining material, hardware, etc., and headquarters of the mining companies whose interests are placed in the mining or dredging of either tin or wolframite ores within a

MAP SHOWING POSITION OF THE TENNASSARIM DISTRICT.

radius of 60 miles, or to the Siam border, less than 50 miles to the east.

The district has been studied and more or less completely mapped by several officers of the Geological Survey Department of India, notably by J. A. Page, and, more recently, by Dr. A. W. G. Bleeck.* The geological conditions, in brief, are a granite or granitic base overlain in parts by schist, sandstone, and quartzite. These constitute the Mergui series of the geologists and may be taken as the local equivalent of the Dharwar series of South India. The chief topographical features are steeply inclined hills rising out of wide, long and nearly flat valleys. These were former arms of the sea, then rivers, and now are rice-flats.

The hills have heights to 5000 ft. as a maximum and average about 2000 ft. It is on these hills that the three classes of quartz lodes are found: (1) wolframite-bearing; (2) cassiterite-wolframite; (3) barren.

They are undoubted fissure-veins due to cooling of the plutonics and of the overlying metamorphosed schist. Frequent slickensides in the latter indicate that dynamic forces were at work to carry the fissures out of the zone of cooling. As far as it is possible to judge at this early stage of development there is little change in strike, dip, or mineral content of the lodes after entering the granite from the schist; the width appears not to be maintained; this being about 2½ ft. in the metamorphics and 1¾ ft. in granite. Those lodes that exist entirely in the latter have the same apparent features as veins in schist; such as cross-courses of chloritic granite, muscovite on the contact walls, sudden swelling and contraction of the lode.

Wolframite occurs in massive, crystalline, and crystal form, and from almost microscopic size up to bodies of several hundredweights. The milky quartz is brittle and vitreous. Associated minerals are tungstic ochre, as a wash or stain, columbite, pyrite, molybdenite, cassiterite, galena, and mica. Pyrite is scarce and only below the oxidation zone; columbite is found amorphous and generally on the walls; molybdenite is common but in negligible amounts and is but medium grade under test for molybdic acid. Cassiterite is of economic importance, unlike galena, in many lodes and occurs patchily throughout the numerous veins that carry it and wolframite. Though usually massive or micro-crystalline, it also is found in large and perfect crystals lining cavities. Samarskite, monazite, and gold are reported to have been found in the district.

Investigation of a lode or lode-series for mining possibilities show that three main points require consideration, namely, the continuity both laterally and in depth, the percentage of wolframite, the grade in units of tungstic acid.

Owing to the height of the hills in which lodes have been worked, the strike-length of these and the recent date (since 1909) of even prospect-mining, there has arisen no necessity to explore the veins in depth and they have to be traced up the hills to obtain any idea of their vertical continuity. On the Hpaungdaw mine, which has been in my charge, one lode out of 15 known to exist on a hill has been almost continuously traced from top to bottom—a distance on the slope of 7020 ft. or 1912 ft. of vertical height. The base length is about three-quarters of a mile. On other portions of the prop-

*'On Some Occurrences of Wolframite Lodes and Deposits in the Tavoy District,' Records Geol. Survey of India, Vol. XLIII, Part 1, 1913.

erty a different lode series has been traced for from 500 to 600 yd. without sign of termination. It is with magnetic bearings ranging from 290 to 320° that these lodes strike, whereas the former series lie due north and south.

To ascertain the amount of wolframite in each lode is impossible in many cases, as no records have been kept, but it is possible to get a fair approximation by measuring all available workings, adding to this the average obtained therefrom for all caved adits and open-cuts; converting this total into tons and comparing with the total tonnage of concentrate gives the percentage of WO_3, which in the case of the Hpaungdaw worked out at 2½% for the entire mine. This is higher than the average for the district and is about equal to the Hermyngyi mine of the Tavoy Concessions.

The final consideration is the proportion of tungstic acid. Private mines and syndicates that sell direct to the German buyers at Hamburg accept the figures of the German government analysts who assay for duty-collecting purposes. Concentrate with less than 60% of acid is of no value. Dr. Bleeck gives 76% as the maximum, but the average grade is not less than 65%, for it is on this basis that the buyers of the German firms give advances against ore delivered at Tavoy. The unit-price remains steady at about 32.5 marks.

One of the greatest drawbacks to any work in Burma requiring labor is the absence of it. The native has only to scratch the soil to get a sufficient return, and in this tilling his women help him; therefore he loafs. In consequence, all mining is done by imported labor, Chinese from the Straits, Ghurkas, Telugus, Ooryas, Tamils, and Pathans from India. The methods are simple and suited to untrained workers.

Having located a lode or lodes, a head-man is given a contract to work it by driving adits at such points as he likes, or, in the case of properly managed concerns, as he is directed. The ore broken is daily looked over, the apparently worthless thrown on the dump together with the country-rock, and the obviously wolframite-bearing rock is hand-crushed, solid ore is picked out, and the mixed product concentrated in a cradle at a stream.

The contractor gets paid at from 10 annas (pence) to 13 annas per *viss* of 3 lb. 8 oz. A deduction of 6% is made for moisture and bag. The bags are double hessian and are returned from Hamburg. A charge is made for candles. Dynamite is free, and is wasted in the most appalling fashion. The contractor is responsible for putting in timber when ordered to do so. No raising or sinking is attempted in many mines. The more vigorously worked properties are getting below the zone of oxidation and find therefore that the cost of driving is increasing so fast that it will probably be found necessary to install two or three small compressors for operating hammer-drills.

Want of capital, dread of a drop in the price of the product, and lack of sufficiently trained managers has prevented the installation of power-drills or of crushing and milling plant, but this reproach is slowly being re-

CRADLE WITH WOLFRAMITE ORE, HPAUNGDAW MINE.

SUCTION DREDGE, HINSHU CHONG MINING & DREDGING CO., LTD.

moved. However, the largest producer, the Hermyngyi mine, obtained all its March output of 54 tons of concentrate by hand-crushing and cradle-dressing, as did the Hpaungdaw with 18½ tons. The former used about 700 men, the latter 190.

Cradle losses have been proved as high as 28%, and as only rich stones are crushed the amount dumped at the adit mouth is fully 95% of that broken. This is worthless, according to the Chinaman, and actually it is without practical value as long as hand-crushing is in vogue.

Various means of transport are employed, such as launches, mules, carts, lorries, or combinations, that is, mules for getting over a mountain and along a jungle tract to the main road where the bags (65 lb. each) go into carts. A mine on or near a river that is tidal to many miles above Tavoy, sends its ore by launch or country-boats. Cost would not exceed 15s. per ton. Against this is the mule and cart transport, which in dry weather will be £4, rising to double in the wet season. The rainfall for the year ended March 31, 1914, was 196.62 in. (the average is about 180 in.), and it is in this season that sluicing is done.

All the ore obtained has to pay a royalty of 2½% *ad valorem* to the Government. In the case of wolframite, the value is assumed at £100 per ton irrespective of grade.

The heavy rainfall and precipitous hills connote water-power, and, without doubt, much will be available as the country is developed. A supply of cheap fuel is at hand on every property in the dense jungle of trees (up to 180 ft.) and bamboo, the cutting down of which will conduce to improved health by extinction of mosquitoes. Producer-gas can be obtained at low cost or the bamboo and timber used for boiler-firing.

During the year ended March 31, 1914, the total tonnage of concentrate was: wolframite, 1622 tons; cassiterite, 68 tons. The output of the latter should be increased, as mixed ores, which are sent to Penang for separation, are recorded as pure wolframite.

A summary of costs gives the following figures, which are above the average:

	£	s.
Mining (timbering, crushing, dressing, incl.)	32	00
Supervision	7	00
Transport (bags included)	4	00
Office, insurance, freight, charges	17	00
Duty	2	10
Total cost per ton	62	10

The Government assumption of the average gross value of a ton of wolframite concentrate is £100. The Hpaungdaw mine on its average tungstic acid content, over 18 months, of 72.8%, shows a value of £125 per ton. Local sales from other concessions are made as low as £88 per ton.

MINERAL PRODUCTION of Iowa in 1913 was valued at $25,602,015, an increase of $2,701,665 over that of 1912. Coal mining and day working account for 80% of the total output.

Mining Near Kiaochow

Coal mining is among the important industries in the German zone in China, now besieged by the Japanese. The following table, printed in the *Daily Consular and Trade Reports*, shows the output of coal and its disposition at the two local coal mines—the Fangtze and the Hungshan—the property of the Shantung Mining Company:

Output and disposition.	Fangtze mine. (Tons.)	Hungshan mine. (Tons.)
Output:		
1912	199,073	374,604
1913	178,600	370,000
Disposition of 1913 output:		
Used at mines	49,200	27,200
Sold at mines	16,200	38,000
Sold along railroad	52,100	110,300
Sold to railroad	14,500	19,500
Bunker and export	5,000	165,000
Sold in Tsingtau	41,600	10,000
Total	178,600	370,000

The same authority says the Fangtze mine has shown a general decline since 1909, when it was at the high-water mark of its prosperity. It is becoming more difficult to work, showing signs of exhaustion, and it will be noticed that 49,200 tons of the 178,600 tons extracted was used in the mines themselves. The output of the Hungshan mine was approximately the same as that of the year before. As the crops were exceedingly good, a cheap fuel has been supplied to the Chinese to the detriment of the coal interests. In January 1913 the Shantung Railway Co. took over the Shantung Mining Co. Mining shares having depreciated on account of the lack of success of the Fangtze, the railway allowed $1,285,200 in railway shares at par value to the stockholders of the mining company for their $2,856,000 of mining stock. It was hoped that the Shantung Railway Co., with its advantages of transportation to and from Tsingtau, would make the mines pay.

It was reported in the *Weekly China Tribune* of May 3, 1914, that valuable iron ore had been found in the Kiaochow district. The paper adds: Recent investigations have shown that samples contain 65% iron, 0.24% manganese, 0.03% phosphorus, and 0.08% sulphur, while the veins of ore are 25 to 50 yd. in thickness. It is estimated that there are about one hundred million tons of ore in the district. Its value is still further increased by the fact that there is a plentiful supply of coal in the vicinity. New ironworks will be erected at Tsangkau, and will have two blast-furnaces, each with an output of 150 tons per day. The capital to be invested will amount to about $2,500,000 gold.

SIXTEEN NISSEN STAMPS have been added to the 80 ordinary stamp-mill of the Modderfontein B. mine, Transvaal. This is the largest number of this type of stamps in any plant on the Rand. It is reported that 12 Nissens are to be installed at the Eileen Alannah mine in Rhodesia.

The Caving System of Mining in Lake Superior Iron Mines*

By J. PARKE CHANNING

The recent statement by me that the late Joseph Sellwood was responsible for the introduction of the caving system of mining in the Lake Superior iron mines has called forth criticism as to the accuracy of my statement, and it is claimed that this method was first used at the Cleveland Hematite mine, which was a soft-ore property lying about half way between Ishpeming and Negaunee.

In 1886, when I went to the Gogebic range for the first time, the Brotherton mine, near the village of Wakefield, was being operated by Joseph Sellwood; he had for the superintendent the late John Pengilly, who had as his two foremen John Harris and Thomas R. Hocking. The mine was wrought on the sub-level system of caving, which I fully described with illustrations in an article entitled 'Lake Superior Iron Ore,' published in Volume III of the 'Mineral Industry,' being for the year 1894. Later on when Mr. Sellwood took charge of the Chandler mine on the Vermilion range, he transferred Mr. Pengilly to that property, and this mine was wrought on a similar system.

In 1890 I left the Gogebic range and went to Ishpeming, Michigan, to take charge of the East New York mine, and took with me for mine foreman Mr. Hocking, who had, up to that time, continued as one of the foremen at the Brotherton mine. We changed the method of mining at the East New York from square sets to caving, and at the same time Thomas F. Cole, who was in charge of the Queen group of mines at Negaunee, introduced this system at his mines with great success and economy. After coming to reside in Ishpeming I visited all the mines in the district, among them the Cleveland Hematite, and I am quite sure that the caving system was not in use at that time.

I have been told that George R. Wallace, afterward manager of the Fayal mine on the Mesabi range, introduced the caving system at the Cleveland Hematite at the suggestion of two North of England miners, who had been accustomed to its use at home. If this is so, evidently the experiment was not considered a success, or else at the time of my residence in Ishpeming it would have been in use at the Cleveland Hematite.

It is a well known psychological fact that similar problems are often solved in an identical manner by men who have had no communication with each other. It is said that Wallace was at work on the 'Origin of Species' at the same time as Darwin, and it is interesting to note that Guy R. Johnson introduced a sub-drift system of mining at Longdale, Virginia, at the Longdale mine, which was almost identical to that of the Brotherton. This method he described in a paper on page 96, Volume XX, of the *Transactions* of the American Institute of Mining Engineers for the year 1891, under the title of 'Methods of Working and Surveying the Mines of the Longdale Iron Company, Virginia.' Mr. Johnson himself told me many years ago that he had never heard of the Brotherton use of this system, and if my memory serves me right, he also said that he had not known of it as the North of England system of mining, but that he and his staff worked it out as the best solution of the problem presented them.

Time is passing and a new generation of mining men is coming in. The Lake Superior Mining Institute is becoming a record of the history of Lake Superior, and I, as one of its charter members, would welcome any information on this interesting question. Most new inventions and discoveries are 95% past experience of others and 5% novelty. He who adds but a little to the world's efficiency deserves credit, and I would be the last one to hold it from him.

*Read before the Lake Superior Institute of Mining Engineers, Marquette meeting.

Mining in Alsace-Lorraine, Germany

This territory is now the scene of considerable fighting, and the mineral output in 1913 should prove of interest.

Product.	Men employed.	Number of mines.	Metric tons, 1912.	Metric tons, 1913.
Iron ore	17,713	48	20,083,238	21,135,554
Coal	16,822	4	3,538,722	3,795,932
Salt	275	8	72,541	76,672
Potash	2,890	17	137,243	350,341
Petroleum	516	6	47,176	49,584
Asphalt		1	5,161	6,354
Total	38,216	84	23,884,081	25,414,437

There were also 293 men employed at quarries and in boring, etc. The potash, salt, and by-products consisted of kainite, 12 to 15%; harkalz, 15 to 20% (a mixture of NaCl, $MgSO_4 \cdot H_2O$, and KCl); fertilizers of 20, 30, and 40%; and chloride of potassium.—Abstract from *Daily Consular Report*.

Phenomena of Adsorption

The effect of the concentration of a solution on rate of adsorption can be very simply shown by the use of an ordinary piece of filter paper. If the dissolved salt is adsorbed faster than the water, a water ring will be formed; if the water is adsorbed faster than the salt, a ring of concentration will be formed. According to the concentration and nature of the solution either one of these may take place. Georgivics and Dietl have recently investigated the physical constants of the sorption of acids by wool and conclude as a result of their work that the process is a combination of adsorption and of solution in the adsorbent. The temperature coefficient for the adsorption of acetic and hydrochloric acids by wool was found to be 1.5. The experimenters point out that the establishing of equilibrium in adsorption may require as much time as several weeks, the process not being as rapid as commonly supposed.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Remarks by Mr. Horwood on T. A. Rickard's Discussion

I greatly appreciate Mr. Rickard's kindly remarks and criticisms. I am glad that in discussing my series of articles on the Rand banket he used the opportunity to review the arguments that have been advanced to explain why the gold is practically confined to the conglomerate beds, and generally occurs only as traces in the intervening quartzites.

Mr. Rickard mentions that I point out that the depth of the deepest existing workings is less than one-fiftieth of the length of the lode as measured along its strike, and that owing to the walls being kept apart by intervening pebble beds, I argue that the extent of profitable ore on the dip is likely to be equal to that ascertained along the strike. He has misunderstood and misquoted me in the latter part of this reference. After pointing out that the economic areas of normal gold quartz veins are usually somewhat fan-shaped in vertical section, resembling sections of inverted cones, I showed that in this particular deposit the function of the fissures had been performed by well defined beds of conglomerate that have necessarily differed from ordinary fissures, inasmuch as they have formed porous channels for their full length along the strike down to a great depth, owing to the walls having been kept apart by the intervening pebble beds. Consequently, instead of the profitable ground tapering downward, it should have, in depth, as great extension *along the strike* as it has at the outcrop. This is a very different thing to saying that the profitable ore should extend on the dip to a depth equal to its length along the strike; such a statement would, of course, be absurd. What I said merely implied that the economic area will be represented in vertical section by a rectangular figure instead of a section of a cone; and that the gradual falling off in value with depth will take place, speaking broadly, along the same horizons from end to end of the banket deposits.

Mr. Rickard says, that when discussing the persistence of value in depth, I dragged a red herring across the trail, and he suggests that I have not admitted a diminution in value with increasing depth. This is incorrect. What I said, in reference to these gold-bearing conglomerates, was "as in all deposits from mineral solution (either liquid or gaseous) that have ascended directly from great depths, or that have been given off as hot primitive solutions by cooling igneous intrusions, a fall in the grade of the ore with depth is to be expected. This is the natural consequence of reduction of temperature and pressure as the solutions ascended nearer to what was then the surface. The laws governing such cases are well known and well understood." I also stated that, "a gradual decrease in the gold tenor with depth is only natural if the bankets represent lodes that have been mineralized by ascending deep-seated solutions (either liquid or gaseous), and, as will be shown, is in this case no cause for alarm. Against the fall in grade with depth, is the important fact that several mines are now working at a profit on low-grade ore yielding about 5 dwt., and even less, and that the working costs at several mines, including these, only average about 13s.6d. per ton." Further, I said, "neglecting the oxidized zone, and any secondarily enriched portions extending below it, the deep-level ground is not so rich as that worked by the outcrop mines."

Mr. Rickard's description of the placer deposits of Nome is very interesting, and, the dissimilarity of such a deposit to those of the Rand is at once apparent, and he rightly contrasts the very slight width of such deposits (in this case 100 ft. at most, corresponding to 100 ft. on the dip of the banket) to the great persistence in depth of the gold contents in the case of the Rand banket.

The analogy he draws between the copper-bearing conglomerates of the Lake Superior district is a very appropriate one. He aptly remarks that "no effort has been made by any American geologist to establish an alluvial origin for the copper"; and, as regards the source of the copper he points out that it is a recognized fact that the basic lavas of the region generally contain native copper; and that the 'copper banket' has been formed by infiltration of solutions from which the metal has been deposited in its native state.

C. B. Horwood.

London, June 1.

True Fissure Veins

The Editor:

Sir—There has been much discussion in this camp as to what is the real meaning of the term 'true fissure vein.' One man that claims to know, says that a *true* fissure vein must cut the formation of the country at an exact right angle to the stratification. I differ with him on this point. I can find nothing in the textbooks that says that it has to cut the formation at right angles. We

would like to learn through your columns the truth about it.

H. C. Burton.

Rosamond, California, August 20.

[With regard to the definition of a 'true fissure vein,' we believe that the term represents more a state of mind than a state of nature. All veins, of course, die out in depth—some of them more quickly than others. Whenever a man has strong hopes that his vein will last indefinitely, he calls it a 'true fissure vein.' Originally, the strongly marked veins which crossed the formations and extended to depths beyond which the miner knew, were called fissure veins. About 1855, J. D. Whitney, in studying the lead and zinc deposits of the upper Mississippi Valley, brought out the fact that the veins there, although of considerable extent, did not extend below the limits of what is now known as the Galena limestone, which is about 250 ft. thick. He had an idea that these veins were formed by contraction of the rock as it solidified and that they were incidental to the particular formation. He therefore called them 'gash veins,' to distinguish them from veins which extend indefinitely in depth and which came to be known in contra-distinction as 'true fissure veins.' For our part, we fail to see any real difference. The veins at Dubuque are often as large and strongly marked as any in the West, and are as true fissure veins as any. The term does not appeal to us as a good one.

Any open fracture in the rock is a fissure, and if it has been filled or partly filled with vein material, it becomes a fissure vein. This is true whether it is 1 ft. or 1000 ft. long and whether it goes down 10 ft. or 1000 ft. Any votes to the contrary?—Editor.]

Revision of the Mining Law

The Editor:

Sir—If evidence were needed to prove the immediate necessity of a widespread 'holler' by those interested in mining, I think it is furnished by Frank P. Davis' own letter in your issue of June 13, and the fear that he may not be alone in the opinions he so clearly sets forth. Since he seems to have covered the ground pretty thoroughly, I shall take the liberty of adopting his framework and clause numbers. With some of his suggestions I agree, as for instance: (1) confining right of location to present and prospective citizens; (7) abolition of extralateral rights; (8) claims to be recorded within a specified time; (10) fine and imprisonment for back dating; (11) the first of July to be the first of the year for mining locations.

Some I regard as debatable. Among these are the following:

2. Changing the size of claims to 1320 ft. by 660 ft. This would have the disadvantage of reducing what is none too large now, though it would have the advantage, in addition to those mentioned by Mr. Davis, of bringing lode claims into conformity with placers; particularly if these dimensions were explicitly stated for placer claims. At present these are without definition except as to area.

13. The security of title conferred by a patent is doubtless a strong argument in favor, but, in view of the fact that in a majority of cases patenting has resulted in a seemingly permanent withdrawal of the territory involved from exploration and development, I believe that the industry in general would be served by the abolition of mineral patents.

Some I sincerely hope may never be adopted, as:

3 and 4. In place of these I suggest that the location stake or monument be placed as at present on the centre line and that the boundaries of the claim be marked within 10 days by two stakes or monuments only, one at either end of the longitudinal centre line. That the location stake or monument may serve for one of these, in which case this would be the point from which all measurements would originate. In case the location stake or monument is not on the end-line, then the end stakes or monuments shall be distinctly marked No. 1 and No. 2, of which No. 1 shall form the initial point for all measurements. Where, owing to timber or irregularity of surface, No. 2 cannot be seen from No. 1, a trail shall be blazed or a series of stakes or monuments erected so that the centre line may be readily traced and permanently located. Our present method of marking a claim by corner and side-line monuments is an everlasting source of confusion and uncertainty for all subsequent neighboring locators. In almost all cases the so-called boundary marks are placed too far out, with the result that there is no fixed point anywhere except the location monument, and that merely serves as a centre for the claim to revolve on to any extent within the widely spread boundaries.

12. Mr. Davis considers payment of a small tax in lieu of doing assessment work as the best of his suggested changes. I consider it incomparably the worst. While it is doubtless true that there is much evasion and wasted energy in connection with assessment work, there is also a vast amount of it useful and productive. I am convinced that the abolition of the assessment work requirement would be nothing short of disastrous to the industry. Great areas in all our mining camps would be indefinitely withdrawn from exploration, as is now the case with much patented ground, while the owners waited for the 'unearned increment' resulting from some one else's enterprise. And even if no valuable discovery had ever been known to result from assessment work, I would still be in favor of its retention in the code, since it is by far the most satisfactory present source of grubstake money for the prospector, 'busted' lessee, and impecunious claim owner.

W. F. Collins.

Battle Mountain, Nevada, June 21.

[We regret greatly that since this discussion began, hope of securing any revision of the mining law has become distinctly less. We can only hope that the next session of Congress may prove more ready to take up this important subject.—Editor.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TOP SLICING the orebody of the Czar mine at Bisbee, Arizona, is under way. The ore is soft, wet, and aluminous, and square-set timbering was expensive and almost impossible.

CHURN-DRILLING at the Giroux mine, Nevada, cost $3.472 per foot during the term August 20, 1913, to April 30, 1914. This includes sampling and assaying, the distance drilled being 14,442 feet.

CAM-SHAFT BEARINGS are sometimes placed between the cams in 5-stamp batteries of heavy pattern. In most instances the system is ultimately discarded in favor of the single bearing toward the end of the shaft.

ALL HOISTS, save the Sacramento, at the Copper Queen mines, Arizona, are operated by compressed air, generated at the central power-plant, by machines having a total capacity of 21,000 cu. ft. of free air per minute.

SMALL QUANTITIES OF MATTE may be removed from cyanide bullion by using common nitre. While the bar is still hot, after pouring, dump it out of the mold, scrape off the slag and drop on the top a few ounces of nitre. It will immediately liquify and the evolution of nitrous oxide fumes will commence. Stir it around with an iron or steel rod, a long cold chisel, or some convenient tool.

LAUNDER CONSTRUCTION for gold and silver mills should increase the grade by about one-fifth around curves, as well as for some distance at the head of the launder, in order to overcome the initial inertia of the pulp until it attains its normal velocity, according to W. A. Caldecott. As a ready approximation for the conversion of degrees to percentage grade, each degree may be taken as equivalent to 1¾% grade.

DREDGING in the Klondike district, near Dawson, has always been interesting on account of the obstacles in the way of straight-forward work. During August, one of the Canadian Klondyke company's boats, No. 4, had the following log for a week's run: operating time, 159 hr. 24 min., equal to 94.9% full time; gravel handled, 102,030 cu. yd; gravel per hour, 640 yd.; power used, 115,680 kw. hours; power per yard, 1.3 kw. hours; average width of cut, 270 ft.; and average depth of bank, 24.7 feet.

IMPROVING THE QUALITY of the water-supply of Manila, Philippine Islands, is being done by adding to the water calcium hypochlorite in quantities corresponding to an addition of from 1 gram of available chlorine in 2000 litres of water to 1 gram in 1200 litres. The bacteria count of the water at San Juan bridge, about three kilometres below the new reservoir, is almost always much lower than that of the water entering the reservoir from the dam at Montalban, and harmful bacteria and organisms are generally eliminated. During the course of the tests a few complaints have been made to the effect that the water has acquired a disagreeable smell. It might be well to point out that the use of hypochlorite is entirely free from poison.

SEEDS OR PITS from peaches are valuable. At Hanford, Kings county, California, a pile of 400 tons of peach pits is stacked on the ground west of the California Fruit Canners' Association packing-house, and several hundred more tons will be shipped in. Los Angeles people, with the necessary machinery, were to have recently gone to the factory to crack the pile of pits, the 'meats' to be shipped to Germany, where they will enter into the manufacture of prussic acid and other products, including the processing of the 'meats' to be used in commerce as bitter almonds. The shells will be sold as fuel.

THE LEAD SMELTER at East Helena, Montana, has been in continuous operation for 25 years, according to Edgar L. Newhouse, and is one of the few essentially lead smelters in the United States, producing 6500 tons of metal per month. It is convenient to two railroads, electric power is obtained 12 miles away, and 450 men are employed. The ore supply is mainly from mines of the Coeur d'Alene, Idaho, and consists of crude ore, coarse and fine concentrate, middling, and slime, representing about 50% of that district's output. These products average 40% lead and 11% sulphur. Other ores come from silicious gold-silver-lead mines in Montana. In order to have a good mixture for the blast-furnaces all products are bedded carefully, the ores being sampled first. Four 42 by 264, and one 30 by 150-in. Dwight-Lloyd sintering machines make a product which is hard and porous, containing from 3.5 to 5% sulphur. The machines travel at 16 to 20 in. per minute, and they will take a very flexible charge of mixed materials. Four 48 by 136-in. blast-furnaces reduce the sintered product, lead going to the drossing plant, and matte to four Godfrey furnaces which reduce sulphur from 20 to 10%. This product is mixed with a direct converting mixture containing not over 10% sulphur, and then roasted in Huntington-Heberlein pots of 12-ton capacity each. The agglomerated mass is then melted in the blast-furnaces. A bag-house receives fume from the blast-furnaces and Dwight-Lloyd machines.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

RENO, NEVADA.

NEVADA STATE MINE-RESCUE AND FIRST-AID MEET.—LABOR DAY CELEBRATION AT RENO.—BUREAU OF MINES AND UNIVERSITY AID IN WORK.—TONOPAH AND McGILL TEAMS WIN FIRST PRIZES.

A mine rescue and first aid contest was held on Mackay athletic field of the University of Nevada, at Reno, on Labor Day, September 7, 1914. The contest was held under the auspices of the engineering college of the University of Nevada with the coöperation of the United States Bureau of Mines, the American Red Cross Society, and the Nevada Industrial Safety Association. This was the first strictly metal-mining meet to be held in the United States, and the first mine-rescue meet at which a mine-rescue maneuvre was performed. The miners who participated in this meet were trained by E. Steidle, mining engineer, and George W. Riggs, first-aid instructor, both attached to Mine-Rescue Car No. 5 of the U. S. Bureau of Mines, which has been touring Nevada since July 1. Sixty-nine miners and 10 University students were trained in mine-rescue work, and 130 miners and 15 students in mine first aid. Weekend lectures in mine rescue and first aid were given by Mr. Steidle, reaching 4400 Nevada miners, and 5250 people visited the rescue car.

Prior to the state meet, two local meets were held in Nevada, the first at Ely, July 4, when 2000 spectators watched eight teams compete, and the other at Tonopah, on August 9, where five teams competed before 1000 onlookers.

Participants in the mine rescue contest underwent physical examination at the hands of doctors at 1:15, and then marched to a position between the bleachers, where a crowd of 3000 spectators had gathered. The model drift shown was designed by E. Steidle, and was constructed of timber, laths, and tarred paper. The side toward the grandstand was left open, with the exception of one section which was filled with dangerous gases, and this was supplied with windows on the grandstand side. The drift was 6 ft. high and 260 ft. long. It consisted of 8 ft. of open drift 6 ft. high, followed by 20 ft. of drift only 3 ft. high to represent a hanging wall. Beyond this came 20 ft. more of open drift and then a gas and smoke chamber 40 ft. long. This chamber was shut off from the rest of the drift by means of swinging doors at either end, and had an inclined obstacle in the centre. At the farther side of the gas and smoke area came 20 ft. more of open drift and then 20 ft. representing a fall, in which the opening was only 3 ft. high above the fall, and finally there was 60 ft. more of open drift to the face. The mine-rescue teams in turn tested their apparatus, adjusted it, and stood a three-minute trial in the small test house, filled with gas and smoke, which was also constructed of timber, laths, and tarred paper, and stood near the entrance to the tunnel. They then entered the tunnel and rescued a miner supposed to have been overcome near the face of the tunnel. A life-line was used, and a stretcher and oxygen breathing apparatus were carried into the mine for the use of the injured man. Teams from the Tonopah Mining Co., the Veteran mine of the Consolidated Copper Co., the Tonopah Belmont Development Co., and the Goldfield Consolidated Mines Co. took part in the contest. The first prize was awarded to the Tonopah Mining Co.'s team, the other teams coming in the order given above.

SCENE AT THE MACKAY FIELD CONTEST AT RENO.

In the mine first-aid contest, teams were entered representing the Nevada Consolidated Copper Co. (concentrator team), the Tonopah Mining Co., Tonopah Extension Mining Co., Goldfield Consolidated Mines Co., West End Consolidated Mining Co., Nevada Consolidated Copper Co. (Veteran mine), and Tonopah Belmont company. The mine first-aid teams worked on the following problem: Miner found in drift under fall of rock in contact with electric wire; rescue patient and re-

store breathing; patient suffering from following injuries: deep electric burn on small of back, scalp wound and left eyeball cut with severe bleeding, right collarbone fractured and simple fracture of right forearm, compound fracture of right thigh five inches from knee, severe bleeding; total time, 25 minutes.

There were also three teams of university students, two from the Mackay School of Mines and one from the electrical engineering department of the University, who contested among themselves. The first prize was won by the McGill concentrator team of the Nevada Consolidated Copper Co.; second by the Tonopah Extension; the third by the Tonopah Belmont. The fourth prize was tied between the West End Consolidated and Goldfield Consolidated teams. The shield and loving cup presented as first prizes were the gifts of the Nevada Industrial Safety Association, while the American Mine Safety Association presented medals to the individual members of the winning teams. The other prizes distributed in these contests included subscriptions to the *Mining and Scientific Press* and other technical papers, and miner's lamps donated by the manufacturers.

Details of the number of men trained and the breathing apparatus on hand in each camp are given in the following table.

Mining district.	Men trained mine rescue work.	Men trained mine first aid.	No. oxygen breathing apparatus.

HOUGHTON, MICHIGAN

CALUMET & HECLA PASSES DIVIDEND.—THE TONNAGE TAX AND OPPOSITION OF THE COPPER COUNTRY COMMERCIAL CLUB.

"In view of the unsettled conditions of the copper market in this country, and the interruption of the Company's business with foreign customers, the directors have decided not to declare dividends at the present time." The above statement was made to stockholders September 1 by the Calumet & Hecla Mining Co. The C. & H. began paying dividends in 1871, and during the period of 43 years has paid $124,250,000 on its 100,000 shares. This amount represents 56% of the total dividends paid by all the Michigan copper companies from 1871 to September 1, 1914. During this long period only once has the C. & H. found it necessary to pass its dividend. In May, 1884, because of the low price of copper and the delays in the sale of the mine products, no dividend was paid. Since 1901 the C. & H. has paid quarterly dividends to stockholders. Two payments have thus far been made in 1914. While a few of the stockholders will probably suffer, the general feeling of the people of the copper country is that under the present conditions of reduced wages and half time, the passing of the dividend by the C. & H. was the only fair and proper thing to do.

Michigan is fortunate in having within its district the active and enthusiastic organization known as the Copper Country Commercial Club. This is an organization of 500 business men and others of Houghton and Keweenaw counties, whose purposes, among others, are to develop confidence in the business and future greatnesa of the locality, to develop economic conditions, and to take all possible means to promote the welfare of all of the people of the copper country. During the recent strike this body of men, through an appointed committee, conducted a most careful and unbiased investigation of the existing conditions and aubmitted to the governor of the state an exhaustive report aetting forth the facts and truth as to wages, hours, labor, and working conditions. The Club has shown lively interest throughout the state in opposing the proposed state tonnage tax. Few people realize that a tonnage tax of one cent per pound on copper would mean a tax of about 47% on the net earnings of Michigan copper mines, and about 62½% of the amount actually received by the stockholders. How could the several companies actually operating at a loss and numerous others producing on such a low margin of profit meet this tax? It is the introduction of new and more economical methods and the most efficient management that make dividends possible at all. The very serious situation of the working people of this district has resulted in the Club appealing to the federal government for assistance, by making substantial purchasea of copper at the present time. A letter has been sent by the Club's secretary to all senators from states interested in the production of copper. The letter calls attention to the critical condition of the Michigan district, and requests that the same assistance which the Government has extended to the silver mines of the West, the cotton growers of the South, the railroads and the farmers, be granted to the copper industry of America.

PLATTEVILLE, WISCONSIN

INCREASED PRICES CLEAN UP THE SURPLUS.—MINES PREPARING FOR LARGE OUTPUT.—LEAD PRODUCTION SLOW.—NEW CONSTRUCTION.

At the beginning of August pricea had reached bottom quotations. The first ten days of the month they ranged from $36 to $40 per ton, 60% zinc content. August 18, producers of sheet zinc, notably the Illinois Zinc Co. and Matthiesen & Hegeler Zinc Co., gave notice that quotations would be withdrawn immediately and offered only on inquiry from bona fide purchasers. Inquiry of one of the largest spelter manufacturing concerns in the United States revealed the fact that the export demand for spelter had become emphatic and the placing of order for shipment of 25,000 tons of spelter in the closing weeks of the month, coupled with an increasing demand for home consumption, sent prices shooting skyward. The close of the month witnessed spelter at seaboard commanding $6.20 per cwt., having advanced within ten days from $4.75, while blende reached $55 per ton of premium ore. Production was slow to respond. Surplus stocks were worked off rapidly and mining companies made haste to get into shape for a maximum production. The month of September should show a decided increase in current production of blende. Buyers are numerous in this field and independent operating concerns fare better just at present than operators selling under contract arrangements. However, everyone is rejoicing in improved conditions.

Lead ore was in poor demand all month and prices were stagnant, very little ore being offered for delivery. Production of pyrite took a disastrous slump and was less than one-third that usually reported. In the northern districts, where great beds of carbonate zinc ore are ready to be drawn on, conditions remain discouragingly quiet. Producers are offering their clean-up for the season, but there is no bidding by the only buyer in the field, the Mineral Point Zinc Co., and miners are complaining.

Sales of ores for the month by districts were made as shown in the following report:

Districts.	Zinc, lb.	Lead, lb.	Sulphur, lb.
Benton	5,922,000	53,100	1,985,000
Galena	3,880,000	58,000	.....
Shullsburg	3,500,000	.....	.....
Livingston	3,374,000	.....	.....
Cuba	2,862,000	.....	.....
Hazel Green	2,424,000	150,900	.....
Harket	1,104,000	.....	.....
Highland	648,000	.....	.....
Linden	740,000	.....	.....
Platteville	614,000	.....	.....
Mineral Point	206,000	.....	.....
Montfort	86,000	.....	.....
Mineral Point Zinc Co...	3,149,800	.....	.....
Totals	28,509,800	262,000	1,985,000

The gross production of wet concentrate for the month amounted to 22,504,430 lb., all grades; net refined ore to smelter, 12,664,400 lb. The reserve tonnage at all points in the field at the close of the month was in excess of 3000 tons held between the Wisconsin Zinc Co. and Vinegar Hill Mining Co. About 1000 tons of lead ore was carried over. A like amount of carbonate zinc ore ready for delivery was also carried over.

The tonnage was distributed among the following buying concerns as shown. Mineral Point Zinc Co., 5713 tons; National Separating Works, 1578 tons; Illinois Zinc Co., 758 tons; M. & H. Zinc Co., 382 tons; Grasselli Chemical Co., 1044; Campbell Separating Works, 1167 tons; American Zinc Co., 250 tons; Empire Roasters, 709 tons; American Metals Co., 867 tons; and Linden Zinc Works, 210 tons.

Two new plants are nearing completion, one a concrete and steel structure at the Little Coker mine of the New Jersey Zinc Co., and one a transformed plant for the B. M. & B. Mining Co., at the Biddick mine. At Platteville the West Hill Mining Co. got into action with a new plant, and the Wisconsin Zinc Co. developed a new producer on the Sitz leasehold. By far the best showing is now being made in the New Diggings district. The Wisconsin Zinc Co. will put into commission, September 15, a plant complete handling 600 tons of mill-rock every 20 hours; the new shaft is complete; a working force of 100 men is being recruited; big bodies of ore were discovered with drill on 600 acres of land, 455 of which the Company secured in fee at $200 per acre. An electrostatic separating plant equipped with Huff machines will be added at a later date. L. V. Rice, general manager for the Fields M. & M. Co. (R. W. Hunt & Co., Engineers) announced on August 25 that the Company would at once begin the development of the Thompson quarter section, in the New Diggings district, putting down a double compartment incline shaft to a vertical depth of 230 ft., with a modern equipment capable of handling 600 tons of mill rock per day. The ore will be handled in automatic dump cars feeding into a Dunne gyratory crusher, everything being taken. The contract is to be complete in 90 days. A gas-producer plant is to be one feature of the new establishment. Three miles of macadam road has been completed from the Crawhall mine to track on the Illinois Central Railway. The first ore to go over the new roadway reached the track August 26. The new plant and mine development will involve an outlay of $100,000. During 10 months of 1913 the Crawhall mine, owned by the Fields M. & M. Co., paid monthly dividends of $30,000. The new range is an extension eastward of the Crawhall mine and mean elevations show orebodies 60 ft. in thickness.

The New Jersey Zinc Co. is completing a new power and concentrating plant on the Penna-Benton mine to go into commission some time during the month of September. The Vinegar Hill Zinc Co. has a new power and concentrating plant ready to begin operation at the Unity mine near Hazel Green. This Company gives employment to 200 men at this time. Several new properties are being developed with success. Two good producers owned by this firm have run their course, the Masbruch and Vinegar Hill, both of which have been abandoned.

McMillan Mining Co., of Milwaukee, is drawing plans for a big power and concentrating establishment on newly discovered zinc ore ranges in the Hazel Green district. The estimates call for a plant valued at $75,000.

JOPLIN, MISSOURI

NEW MILLS FOR HANFORD AND UNITED ZINC CO'S MINES.—DEVELOPMENT IN THOMS STATION DISTRICT.—REOPENING OLD CLAIMS.

A concentrating plant of 250-ton daily capacity is being constructed by the Hanford Mining Co., operating on a lease of the Mattes Bros.' land at Gordon Hollow, southwest of Joplin. The mill will replace one of smaller capacity which formerly was situated on this tract and which was destroyed by fire several months ago. J. S. Handford, of Forth Worth, Texas, is president of the Company. The mill building will be 110 ft. long by 28 ft. wide and will be equipped with cleaner and rougher jigs, sand jigs, and sludge tables. The boiler room will be 28 ft. square, and the engine-room will be 30 by 50 ft. Gas will be used for fuel. Mining operations will be conducted at a depth of 117 feet.

On a lease of the General Lead & Zinc Co.'s land in the Thoms Station district north of Joplin, J. N. Hill, W. M. Waters, Thomas Kinmouth, Charles Turner, William Brockman, and associates are sinking a shaft, where 10 years ago Mr. Hill and others undertook to get a shaft down to good ore which had been revealed in three drill-holes. At that time, however, there was little mining at Thoms Station, and consequently the problem of lowering the water was much more difficult than it is today when so many mines are at work. At that time a large pump, which in those days was considered the acme of efficiency, was used without success. Today the Company has the shaft to a greater depth than before, and yet the water is handled with a barrel bailer. A large derrick is now under course of construction and steam equipment for hoisting, and pumping also if the flow of water increases with depth, is to be installed. The lease comprises 20 acres at 10% royalty, with the option of taking an additional 20 acres if a mill is built. The shaft is now down to a depth of 125 ft., and zincblende in quantity is beginning to appear on the north side. The drill holes showed the ore to continue down to a depth of 160 feet.

Much work of real importance is being conducted in some of the old camps which for some time have been idle. The reopening of old mines that have been non-productive for some time is, in a sense, almost as important to the district's welfare as the opening of new properties, as it often transpires that the erstwhile heavy producer, long idle, can be revived and developed into a big producer. Numerous examples can be given. For instance, the Century, at Neck City, is on land that had been extensively mined, later to remain idle for years. The present production from the tract far exceeds anything previously reported. In the West Galena, Kansas, district, a dozen new companies are working on the Templar Mining Co.'s land. Ore is found at comparatively shallow depths. Small companies find this class of development inexpensive, and many of them sell their crushed rock in the rough as it comes from the ground, receiving on an average of $4 or $5 per ton for it, although an occasional rich pocket is cut which will yield $10 per ton.

Pumps have been installed on the Bob Ingersoll lease of the United Zinc Co.'s land, Chitwood camp, northwest of Jop-

lin, and will drain the old workings of this once famous zinc ore producer. Work will be conducted at a depth of 170 ft. Ore has been shown in drill holes sunk some distance in advance of the old headings. Messrs. C. H. Aldrich, of Chicago, and J. F. Jet, of Louisville, Kentucky, are operators of this mine. They contemplate the construction of a mill. Another mill is proposed on a lease of the same land, formerly operated by the Conqueror Zinc Co. Blosser and associates, of Pittsburgh, Pennsylvania, are operators of this property. Ore has been shown in several drill holes at a depth of 165 feet.

The first drilling done in recent years on the land of the Missouri Lead & Zinc Co., in the southeast part of Joplin, has been launched by two Companies, the Pedagogue Mining Co., composed chiefly of Joplin school teachers, and the J. J. Haggart Mining Co. Both companies have operated in shallow ore deposits. They intend to test the deeper ground.

The Underwriters Land Co., operating on the Connor land, west of Joplin, has begun sinking a new shaft south of its mill to open a shallow run of soft ore shown in several drill holes on this portion of the land. The Company has worked in sheet ore at a depth of 125 ft. The soft ore was cut unexpectedly at a depth of 70 ft., and the deeper sheet-ore formation was not in evidence. On the west portion of the Underwriters lease a small flotation plant is handling the sludge from the mill, and about five tons of concentrate per week is being placed in the bin.

NEW YORK

COMPANIES PAYING DIVIDENDS.—SMELTING AND RAILWAYS IN MEXICO.—COPPER REFINERIES.

Dividends declared by mining companies in September are as follows:

Company.	Per cent.	Per share.
Butte & Superior	..	$0.75
Chino	..	0.75
Crown Reserve	2	....
Grand Central	..	0.05
Hedley	3 + 2	....
Hollinger	..	0.15
Homestake	..	0.65
McKinley-Darragh	..	0.03
Nipissing	5	....
Phelps, Dodge & Co	2½	....
Tennessee Copper	..	0.75
Utah Copper	..	0.75
Wolverine	..	2.00
Yukon Gold	..	0.075

The Chino distribution is a reduction of 50c. per share; Phelps, Dodge & Co. omitted the extra dividend; the Yukon Gold is paid from earnings, and not surplus; and Nevada Consolidated and Ray Consolidated have deferred payment for the present.

The American Smelting & Refining Co. is gradually getting its Mexican properties going again, four of the six furnaces at Chihuahua have been blown in, and a fifth will be started soon. Preparations are well advanced to blow in the plant at Aguascalientes. Chihuahua is fortunately placed in that it is not so dependent on transportation as the other smelters, the ore being just at hand. The plants which depend on railroads are less well placed, for with three year's attempts to destroy the lines, superimposed on an equal period of neglect, the lines are in a precarious condition. Now that all Europe is engaged in war, it is impossible for the Mexican railways to raise any money for repairs and reconstruction. Carranza has now taken over the National Railway system, and given it a new name.

Copper refineries are now beginning to feel the cut in output, and are beginning to curtail also. This probably means that the refineries will decrease their output and call on the mines to help carry the stocks, which are bound to accumulate as a result of the effect of the war situation. The Nichols refinery, which was fortunate enough to have a strike which interfered with its output coincide with the strike in the Lake Superior region, is similarly fortunate again, and the troubles which it is now having with its refining furnaces will automatically curtail its output.

MAIN SHAFT, POWER-HOUSE, CRUSHER PLANT, ORE-BINS, DORMITORY, AND MESS-HOUSES AT INSPIRATION.

BOSTON

NEVADA-DOUGLAS AFFAIRS.—BUTTE CENTRAL MINE.—NEWBURY MINING CO.—MONTANA RAILROAD FINANCE.—MEXICAN METALS CO.—COPPER AND ZINC.

Promoters of the Nevada-Douglas here are taking a new lease on life and claim that the leaching plant under construction at the property will give it earnings of at least $1 per share. There is no projected or pending leaching process anywhere in the country which is being quite as extravagantly presented as this one, a favorite statement being that the Company will when operating under new conditions be able to get its copper for nothing. Nevada-Douglas shares have sold as high as $7 and as low as about 70c. The property is a large and probably valuable one, but the policy of handling it has not been popular in Boston, and consequently the financing and development have been slow.

Interests here which are reorganizing the Butte Central company, at Butte, express confidence that they will be able to operate the mill at an early date. The new Company bears the name of Butte Central Mining & Milling Co., and capitalization has been reduced to $750,000, with an issue of bonds. It is proposed to run the mill in a small way on custom ores, turn over the upper levels of the mines to lessees, and sink the shaft below the 500-ft. level later on, when funds are available. The mill is a good one, both in type and construction, and represents the first application of the cyanide process to certain Butte ores.

It is understood here that negotiations have been completed by which the control and management of the Newbury Mining Co. has passed to Makeever Brothers, of Boston and Chicago. The Newbury company was organized in 1901 with a capitalization of $2,000,000. The property consists of about 50 acres and a smelter site on the Gila river, near Florence, Arizona. In the days of the old chloriders it was worked for silver, and has four veins, with silver content changing to copper at depths of 285 to 350 ft. Considerable development has been done, though but little in recent years. There is a 300-ft. adit and four shafts. Statements have been made that there were ore reserves blocked out of approximately 200,000 tons, averaging about 4% copper, $6 gold, and some silver, but it is thought these estimates have been exaggerated. Considerable stock of this Company has been distributed throughout New England, and up to the time the prop-

erty became inactive, several years ago, it was considered to be a promising project. Makeever Brothers have been operating successfully in mines for a number of years, largely in Mexico. A year or so ago they took over a property in Montana.

W. R. Allen, of Butte, has recently been spending a few days in Boston in conference with Sir Frederick W. Borden and others respecting the plans of the Boston & Montana Development Co. and the Southern Montana Railway. The directors of the former Company entered into a contract last spring with the McArthur Brothers & Perks interests, of London, New York, and Ottawa, to build the railroad, about 100 miles long, south of Butte to reach two mining districts, French Gulch and Elkhorn, controlled by the Company. Sir Robert W. Perks agreed to assume the raising of the bulk of the money needed to complete this contract, and it was arranged to float $3,000,000 of the railroad company's bonds in England. The outbreak of the war checked the program, but the English interests are confident that the plans can be carried out as soon as the Allies have won a decisive victory over the German and Austrian forces. Mr. Allen, who was a few years ago lieutenant-governor of Montana, was a director in the State Savings Bank, of Butte, which recently was placed in the hands of a receiver.

The Mexican Metals Co., which has been active in Cananea, Mexico, from September 1911 to last February, has ceased to operate, and at the annual meeting of the stockholders held in Bisbee on September 14, the question was considered favorably of acquiring 100,000 shares of the capital stock of the Cananea Mining & Development Co. it was also decided to authorize the directors to purchase new properties for the Company, according to their judgment. They were also authorized to sell or abandon such property in Mexico owned by the Company, indirectly through its ownership of the Moctezuma-Arizpe Development Co., as in their judgment may be best for the Company. The operations of the Company have been very disappointing. A geological survey of the property was made by J. M. Little, formerly with the Greene-Cananea company, who stated that a part of the extensive territory does not contain commercial ore. This survey was checked by Allen H. Rogers, of Boston, in connection with Franklin W. Smith, of Bisbee, two well known mining engineers, and their advice was to shut down operations. The principal interests in this Company are the Keiths, of Brockton, Massachusetts, large shoe manufacturers. The stock has been extensively manipulated on the Boston Curb.

The Copper Producers' Association having discontinued its monthly statements for two months, it is not likely that there will be any statement issued until the Stock Exchanges reopen. The faction which has been opposing the publication of the figures ever since they were started several years ago, is now taking advantage of the present situation to discourage the resumption of monthly reports. It is claimed by those who oppose the publication of statistics that the plan has always worked to the disadvantage of the producers, who were paying the bills.

BULAWAYO, RHODESIA

MINERAL PRODUCTION OF THE TERRITORY.—SURPLUS OF NATIVE LABOR.—SHORTAGE OF WATER AND DEVICES TO REDUCE CONSUMPTION.

Some little time ago the secretary of mines for Southern Rhodesia predicted the current year's mineral output would be worth £4,000,000. It now certainly looks as if this cheerful forecast will be very nearly, if not quite, fulfilled. The value of gold alone recovered during the period to May 31 last was £1,368,125, compared with £1,171,867 in the corresponding five months of 1913. This rate of gold production may be confidently expected to improve during the next few months. Neither the Shamva nor the Cam & Motor equipments have at the time of writing attained to normal running efficiency, and in addition to improvement that may safely be counted on from these two properties the Golden Kopje and Falcon are just commencing production. In minerals other than gold, too, the outlook for larger returns is good. Recent discoveries in the Victoria district foreshadow an increase in the chrome iron ore and asbestos outputs. The Wankie Colliery Co., having recently concluded important negotiations with the Union Minière for the supply of coal and coke to the Katanga copper mines, may be expected to record increased sales. Diamond production has been resumed in the Somabula area, and the Falcon, in addition to its gold output, will produce fair quantities of copper. Altogether then the prospect of a continued advance in Rhodesia's mineral output for some time to come is undoubtedly good.

A remarkable state of affairs in regard to native labor in Southern Rhodesia was disclosed by P. B. S. Wrey at the third annual meeting of the Rhodesian Native Labor Bureau held in Bulawayo a short time ago. The acting chairman stated that there was a surplus of natives, an extraordinary position in South Africa, a country continually crying out for more cheap colored labor. Mr. Wrey pointed out that in October last there was a surplus amounting to 1200 boys, but owing to the exertions of the mining members this was duly absorbed. Recruiting has, however, since been continued, and the position at present is that there are 2000 natives in the Salisbury compound, which the industries of the country have failed to absorb. Notwithstanding this, it was reported at the meeting that the managing director was absent in Lourenco Marquez negotiating with the Portuguese government with a view to recruiting colored laborers for the mines and farms of Southern Rhodesia, in what is known as the Tete area. It is certainly anomalous that while other industries in South Africa are handicapped on account of shortage of unskilled labor, the Rhodesian Native Labor Bureau should be put to considerable expense in maintaining surplus labor within its compounds.

That a number of mines in Southern Rhodesia have been much hampered during the past two or three years by lack of water admits, unfortunately, of no dispute. Moreover, there is a good deal of evidence to support the view that the drought has become more serious each year. Large, as well as small mines, have been hard hit during protracted dry seasons, through insufficiency of water for milling purposes, but scarcity of water has troubled the small workers more than the limited liability companies, which naturally can afford to take measures of conservation and storage, which the miniature mine-owners, because of limited capital, are unable to do. In both Matabeleland and Mashonaland numerous inventions and suggestions have recently been made with a view to water economy, and perhaps exhaust steam from non-condensing engines has received most of this attention. The latest device has been invented by T. Warwick, who has had great trouble at his mine in the Betingwe district on account of water shortage. The invention makes use of the pipe-line running to the mill. This is jacketed for a length, depending on the size of the engine, the jacket being made with two longitudinal joints so that it may be installed without breaking a joint, or in any way altering the pipe-line. The steam enters at the lower end of the jacket at a special cast iron "T" cast in halves. As the steam travels onward the upper end it condenses and the water gravitates down the jacket to the outlet whence it enters an oil separator, from which it is passed to the boiler feed tank at a temperature of about 180° F. Among the advantages claimed for the Warwick patent condenser are that there is a condensation of 90 to 95%, giving a feed water free from dissolved matter, no upkeep costs, or delays for cleaning, simplicity both in working and erection, and a saving of about 10% in the fuel bill.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

(Telegraphic Correspondence.)—The widely published statement credited to Stephen Birch, to the effect that important discoveries of gold-bearing quartz lodes had been made at Broad Pass at the head of the Susitna, is denied at the office of the Alaska Syndicate.

New York, September 16.

Bethel

(Special Correspondence.)—Mining is progressing slowly but satisfactorily in this part of the territory. From a new discovery on Quisluk river, three men took out $3000 in 20 days' shoveling into boxes. This is the first output of any consequence from this area. A short distance from there on Eek river some men are working, but results are not known. The only drawback to the district is transport facilities, as will be seen from the fact that Mr. Hoffman, one of the larger traders on the river, who had 75 tons of supplies last year, and was short before the river broke in the spring, has not received this spring any of the goods he ordered for this summer and coming year. Chances are poor for him to get any at all this summer, and there are a number of other small traders who are in the same position. Shafer & Brown at Bethel informed me that there were things they were out of already, and no chances of getting further stocks this season. Last winter supplies were freighted in from Iditarod to Aniak river. So under these conditions the district cannot be but slowly developed. At present there are only two places where miners can get material, and they are Bethel and Takutna, 500 miles apart. The Good News Boy district can get some from Gwinhagak (Moravian Mission).

Bethel, August 1.

ARIZONA

Cochise County

Material for the 10-mile railroad from Willcox to Dos Cabezas is being unloaded at the former place. The Mascot Copper Co. is financing the work. The Dos Cabezas district is promising.

Gila County

Owing to the war in Europe, the supply of potash cartridges for Draeger mine-rescue helmets is cut off from Germany. According to Orr Woodburn, of the Old Dominion mine, these cartridges are essential for the apparatus.

Salt Lake City people, who compose the Gila Canyon Copper Co., at Chilito, are prospecting the porphyry deposits by drilling. A Keystone outfit is boring 75 ft. in two shifts, and the first hole will be 1000 ft. deep. The first 75 ft. assayed 0.6% copper. Approximately 5000 tons of 10% copper ore has already been produced and the property is earning at present about $2000 per month from shipments of first-class ore.

Mohave County

Tom Reed mine produced gold worth approximately $100,000 in August. Experiments are under way in the cyanide plant for better work.——The Gold Road continues to produce about $20,000 per week, this being taken to Kingman by George W. Ayers.——Work is being resumed at the Frisco Gold mines.——Good ore has been opened below 200 ft. in the Arabian Consolidated mine.

Yavapai County.

Over 40 men are busy panning, rocking, and sluicing gravel in the Stanton district near Congress Junction. Recent heavy rain has provided plenty of water for the work, the first time for some years.——Phelps, Dodge & Co. has taken a bond and lease on the Black Diamond mine near Jerome. The ore contains copper and silver.——At 300 ft. in the Little Jessie, at Chaparral, 30 in. of gold ore has been cut.

CALIFORNIA

Calaveras County

At the Stockton Ridge gravel mine, near Mokelumne Hill, the main adit is in 3100 ft., in which 100 ft. of the channel has been exposed. A ventilating shaft is being sunk 420 ft. to connect with the workings, the present rate at 130 ft. being 9 ft. per day. An electric locomotive is to be used to haul gravel to the mill, which contains a Price machine of 300-ton capacity per day. A good deal of equipment has been placed on the property, and $75,000 has been spent. Stephen Hughes is in charge.

Eldorado County

Collapse of timber and a fall of ground entombed W. Williams 500 ft. from the mouth of the Alderson mine adit last week. A rescue party made a small opening through 15 ft. of material and rescued him in 12 hours.

Modoc County

Ore worth up to $150 per ton has been opened at 100 ft. in the Modoc mine, 11 miles from Fort Bidwell. There are 25 men employed.

Nevada County

Officials from Rescue Car No. 5, which is at Colfax, have been giving instruction in first-aid work at the Empire, North Star, and other mines at Grass Valley.

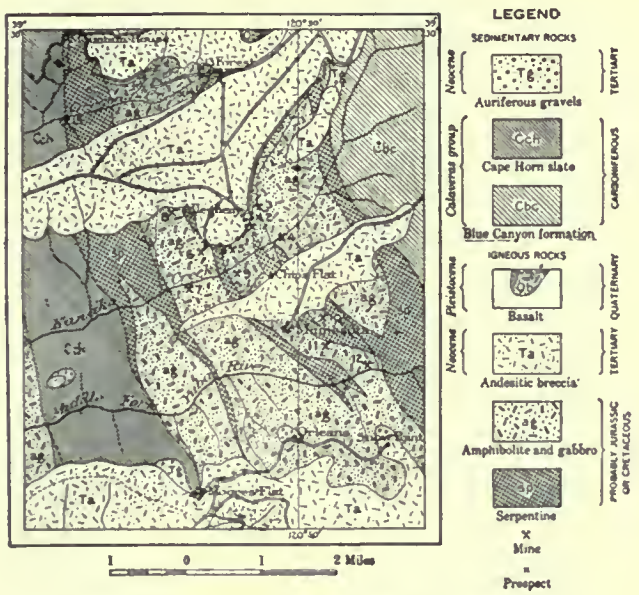
Shasta County

Owing to the improved market for spelter, the Afterthought mine, near Ingot, is to produce zinc ore.——Flume construction and other work is under way for the placer claims of C. R. Thorpe and H. C. Quirk.——James Hulme, former owner of the Gold Leaf mine near Redding, has resumed development.——At the Mammoth smelter at Kennett extensive improvments are being made to the bag-house, etc. Two furnaces out of five are in blast.

Sierra County

The lode deposits of the Alleghany district are described in *Bulletin* 580-I of the U. S. Geological Survey, by Henry G. Ferguson. He states that the area is not only interesting on account of small rich shoots of gold ore, but the problems they offer in the study of vein formation are important. Mining has been done since about 1860, and the output to date is about $5,000,000. With the finding of the Tightner vein by H. L. Johnson in 1907, the district started a new life, and since then the output to 1913 has been 51,364 tons of ore for $733,035, from 3, 8, 3, 8, and 5 mines, respectively, for the five years. The gangue is mainly quartz, and arsenopyrite the most important sulphide, the latter being rich and is an indicator of shoots of rich ore. The following mines are described briefly: Tightner, Minnie D., Osceola, Eldorado, Sixteen to One, Sherman, Kenton, Oriental Rainbow, Plumbago, Irelan, Gold Canyon, North Fork, Federal, and Kate Hardy, which are numbered on the accompanying map in this order.

Owners of the Kate Hardy have secured a bond on the southern extension of their claims and will drive north on



GEOLOGIC MAP OF THE ALLEGHANY DISTRICT.

the vein.——A new air-compressor and machine-drills have been installed at the North Fork, where the shaft is being sunk to 200 feet.

COLORADO

Clear Creek County

The Waldorf mill is working steadily and 30 tons of ore is treated per shift at present. Concentrate from the 7 tables and mine jigs assays $30 per ton.——There is now 24 in. of ore in the main drift of the Big Indian mine.——The Kane adit of the Capital mine is in 800 ft., with a similar distance to be driven before sinking is started. The main raise has been stopped and connection will be made with the adit by sinking a winze to meet the raise. Lessees in the Capital mine are as busy as usual.——Rich gold-silver ore has been cut in a raise in the Centennial.——Rich silver ore is being sacked from the Franz Joseph mine by Hugo Lendecke.

Chaffee County

The St. Elmo Mining & Milling Co. is building a custom mill at St. Elmo. The principal part of the equipment consists of one 8 by 12-in. Denver crusher, one automatic Denver feeder, one No. 2 Denver quartz mill, two 52 by 96-in. amalgamating plates, two Wilfley and one Ishell concentrating tables. The contract for the machinery has been given to the Denver Quartz Mill & Crusher Co., of Denver.

San Juan County

Ore and concentrate for the Silverton district in August amounted to 14 and 96 cars, respectively, the Gold King supplying 30, Iowa Tiger 28, and Sunnyside 21 cars of concentrate.

San Miguel County

During August the Tomboy mill treated 12,600 tons of ore yielding bullion worth $33,000 and $47,500 from concentrate shipped. The profit was $34,180.

Teller County (Cripple Creek)

Water flowing from the Roosevelt tunnel is now about 9200 gal. per minute.——Sinking is in progress at the Golden Cycle, Granite, South Burns, and Vindicator main shafts, and will be resumed at other properties later on. Developments at depth have been generally encouraging.——Lessees at the Deerhorn and blocks of the Stratton estate are mining from two to four cars of ore per week, from shoots only 35 ft. from the surface.——There are 10 sets of sub-lessees at the Midget-Bonanza mine, and Hickman, Davis & Co. have opened ounce ore near the surface.———In ground southwest of the main shaft the Elkton company has opened $18 to $20 ore.——The new Chilean mill at the Neville mill is at work, and the total capacity of the plant will be 60 tons per day.——Owing to an accident to the crusher, the Gaylord mill has been temporarily stopped.

IDAHO

Shoshone County

Development still proceeds at the National copper mine near Mullan, and an assessment of 3c. per share on 2,500,000 shares is due October 5. The mill is still closed.——The adit at the Hector is in 4200 ft., the depth being 1600 ft., and the vein should be cut in 250 ft. Water Leyner drills are to be installed, the ground being hard. Arthur George is manager. ——Thirty feet of ore has been cut in the Silver Cable, and assays return up to 30% zinc.——The Hypotheek shaft is to be sunk from 840 to 940 ft. The ore-shoot at 700 ft. is 6 ft. wide for 540 feet.

MONTANA

Granite County

The Royal Basin Mining Co.'s mill at Maxville is nearing completion. The first unit of 250-ton capacity is about ready and the second will be in about a month. The Fields' flotation process will recover the copper minerals, a test plant having shown good results.

Silverbow County

As the result of continued trouble with the miners at Butte, on September 8 the various mining companies concerned issued a statement in which it was shown that all agreed neither to recognize the Butte Miners' Union No. 1, Western Federation of Miners, nor the Butte Mine Workers' Union. Thus Butte becomes an 'open-shop' district, it having been a union stronghold for 36 years. No changes will be made in the wage scale. Those Companies signing the statement are as follows: Anaconda Copper Mining Co., North Butte Mining Co., Butte & Superior Copper Co., Butte Ballaklava Copper Co., Elm Orlu Mining Co., Timber Butte Milling Co., Butte Alex Scott Copper Co., Pilot-Butte Mining Co., Tuolumne Copper Mining Co., East Butte Copper Mining Co., Rainbow Development Co., and Butte-Duluth Mining Co. Union men were taken by surprise, but have said or done nothing yet. The militia is destroying liquor found in saloons open in defiance of orders. Several arrests are being made.

August output of the Butte & Superior was as follows: ore treated, 30,440 tons; concentrate produced, 11,297 tons; average assay, 49.16% zinc; and recovery, 90.43 per cent.

NEVADA

Elko County

The Flaxie Mines Co., held its annual meeting at Jarbidge on August 31. Water-power rights on Bear creek have been secured. About 600 tons of $33 ore has been opened above the adit, and 60 ft. below good ore still shows. A small mill and cyanide plant is proposed. James Johns is superintendent.

Esmeralda County

Instead of sending 100 tons of ore per day to the Goldfield Consolidated mill, the Jumbo Extension company has reduced this to 45 tons, and increased shipments to smelters to about 30 tons per day. The latter ore contains copper, necessitating this change.

Humboldt County

In addition to the mill under construction, another one is proposed for the Rochester district.——After being idle for 30 years the old Moonlight mine near Unionville is to be reopened. Rich silver ore was obtained in the early days. G. D. Blood and associates, of Salt Lake City, now control the property.

(Special Correspondence.)—Important changes have taken

place in the management of one of the principal mines of Rochester. Through foreclosure proceedings and sale, the Mexican company, operating on the Comstock, has secured 500,000 of the 650,000 issued shares of the Rochester Weaver Mining Co. In the first week in September two of the three directors resigned, their places being filled by the election of Whitman Symmes, general manager, and Mr. Jacobsen, superintendent, of the Mexican company, and the office and books were removed to the office of this company at Virginia City. Joseph F. Nenzel, former owner of the stock acquired by the Mexican, retains the position of president of the Company, and is the third director. The Rochester Weaver has an authorized capital stock of 1,000,000 shares, and ore reserves estimated at 15,000 tons developed by tributers. Besides the Rochester Weaver stock the Mexican company has acquired 150,000 shares of the Rochester Mines Co., of which Company Mr. Nenzel was formerly president, having recently been succeeded by John F. Cowan, of Salt Lake City, after a prolonged fight in the courts of Nevada. The Rochester Mines and Rochester Weaver stock referred to was pledged to the Mexican company by Mr. Nenzel about a year ago, to secure the payment of a loan of $45,000. The Rochester Mines Co. has an authorized capital stock of $1,250,000, represented by 1,250,000 shares of stock, of which 870,000 shares are issued.

Rochester, September 14.

The new vein in the Codd lease of the Rochester Hills Co. has been cut in the Big Four claim, proving the vein to extend through four leases. In the Codd lease is 10 ft. of rich ore at a depth of 600 ft. In the Four J lease adjoining, has been opened a wide lode of $18 ore. A total length of about 1000 ft. of mill ore has now been proved in the four leases.

Lincoln County

The Prince Consolidated company, at Pioche, has acquired control of the Virginia Louise company. The latter's property is opened by a 465-ft. shaft, and a large orebody has been proved. M. C. Godbe is manager of the Prince Consolidated.——In August the Gold Chief mine, near Caliente, treated about 40 tons per day yielding between $5000 and $6000. H. W. Rand, of Portland, Oregon, is manager.——A heavy flow of water was met with on No. 14 level of the Amalgamated Pioche on September 3. No. 12 level stope is producing up to 100 tons of zinc ore per week. Flotation is said to be suitable for this ore.

Lyon County

The Nevada-Douglas mine produced 1843 tons of dry ore, yielding 243,211 lb. copper in August.

Mineral County

The Aurora mill is now treating 200 tons of ore per day yielding $3.40 per ton. The Company employs 150 men on the property.

In the 4000-ft. adit of the Lucky Boy mine, near Hawthorne, 24 to 36 in. of rich silver-lead ore has been opened in limestone. Twenty men under Morris Gallagher are driving the adit 8 ft. per day in hard ground, according to G. W. Ingalls of Reno.

Nye County

(Special Correspondence.)—The Round Mountain company has started sinking the main incline shaft from the 700 to the 900 ft. level, and will hasten the work in order to make connections with the Sphinx mine working at 800 ft. The Sphinx was acquired on August 1 by the payment of $20,000 and $175,000 in shares of Round Mountain stock. At the time the deal was consummated the Sphinx dismissed its suit against the Round Mountain company, and Wm. Forman of Tonopah, its attorney, was elected a director for that company. The Round Mountain company has discovered a good body of ore in the Sphinx since assuming charge of that mine, a faulted segment of the vein which was missed by the Sphinx management. The lease which the hydraulic company held on Round Mountain placer ground expires May 1, 1915, and the Company is making arrangements to work its own placer. The water-rights of Jett cañon, eight miles distant across Smoky valley, have been purchased, and a pipe-line is to be constructed this year, to provide water for hydraulicking next year, and to insure an ample supply for the mill should enlargement of its capacity be found advisable. The plant has a capacity of 5000 tons per month. During the past four months the Round Mountain company has earned $40,000 net, and now has $75,000 in its treasury. Of the capital stock of $1,500,000 shares, 1,087,519 are issued. The last dividend, of 4c. per share, was paid in August, 1913.

Round Mountain, September 5.

It is reported that the Manhattan Consolidated Mining & Milling Co. has taken a bond and option on all the important properties in the western portion of Manhattan, including the Mustang, Big Pine, Mayflower, Big Four, Jumping Jack, Indian Camp, and Stray Dog mines. Ore from the different mines is being tested at the War Eagle mill, and holes will be drilled to a depth exceeding 2000 ft. below the workings.

The Belmont district, 47 miles north of Tonopah, which has been practically deserted for 30 years, is to have a new lease of life. Nelson Bros., who own several claims there, have arranged with the Nevada-California Power Co. to extend its power line from Manhattan, 14 miles away. A large production of silver was made in the camp from 1864 to 1885, but it cost up to $40 per ton to mine and treat ore. The company controlled by Nelson Bros. is called the Monitor Belmont Mining Co., and a mill is being constructed.

Mines at Tonopah produced 9425 tons of ore worth $196,540 last week.——At the Labor Day sports at Reno, teams from Tonopah mines won four prizes in first-aid and mine-rescue contests.——At 900 ft. in the Desert Queen workings of the Belmont, 9 ft. of $70 to $100, and 3 ft. of rich ore has been cut in trachyte formation.——Stopes on the Macdonald, Martha, and Triangle veins of the Montana mine continue to furnish plenty of ore for the mill.

White Pine County

Safety First, the monthly bulletin of the Nevada Consolidated company, states that August was an unfortunate month for accidents. At Copper Flat, five men were killed and three seriously injured on August 4, by the punching and striking with a hardwood tamper, some dynamite lodged on a rock which had by accident become jammed in the barrel of a blast-hole. At the Veteran mine, concentrator, and smelter there were several more or less serious accidents. A team from the concentrator captured first prize for first-aid at Reno on Labor Day.

NEW MEXICO

Grant County

At the Chino company's mine, mill, power-plant, and residences a total of 600,000,000 gal. of water is required per month. But 83% of this is recovered, and the balance, about 100,000,000 gal., is lost. This amount must be replenished each month, and as the supply has been difficult to obtain at times, seven spring and dam sites capable of delivering 196,000,000 gal. per month have been obtained. There is now stored 375,000,000 gal. above the three tailing ponds below the mill at Hurley.

SOUTH DAKOTA

Lawrence County

(Special Correspondence.)—At the annual meeting of the Golden Reward Consolidated Gold Mining & Milling Co., held at Deadwood, the following directors were elected: C. C. Tegethoff, O. H. Kahn, Harris Franklin, Robert W. Goelet, H. W. DeForest, W. B. Devereux, Walter Luttgen, E. C. DeWitt, and W. A. Harriman, all of New York. The officers are:

C. C. Tegethoff, president; Harris Franklin, vice-president; W. J. Johnson, secretary; and N. E. Franklin, assistant secretary.——The regular monthly dividend of 1c. per share was declared by the directors of the Wasp No. 2 Mining Co. on August 15. Everything about the plant is running smoothly. ——Permission having been given the Heidelberg Mining Co. by the South Dakota 'blue-sky' commission, to sell treasury stock, sinking has commenced with the funds raised, and a shaft will be put down below the present deepest level, and, simultaneously, a raise made to the surface, a distance of 100 ft., directly over the shaft, to be connected with it, and thus give exit to the surface. A windlass will be used in sinking until such time as a steam plant can be erected on the surface and connections made.——S. T. Cochran was elected president, J. N. Andrews vice-president and secretary, and Banks Stewart treasurer and general manager, of the Hidden Treasure Gold Mining Co. at a meeting held in Deadwood. These officers and a number of stockholders visited the property at the time of the meeting, and discussed plans for future development. It is probable the shaft, now 200 ft. deep, will be continued. It is equipped with a gasoline plant.

Since the establishment of an assay office and the employment of an assayer at the Titanic property, the workings and surface outcrops are being systematically and thoroughly sampled. The work is well in hand, but will probably require the balance of the summer to complete. The company recently purchased the Albe fraction from Mrs. Ellen Holmes, the owner. This was a small acreage, but was situated at what might be called a strategic point.

Deadwood, August 20.

UTAH

Juab County

Zinc ore, containing 35% metal, is being shipped from the Lower Mammoth mine.——On the 600-ft. level of the old Mammoth mine, a new shoot has been cut which assays from 3 to 19% copper, 1 oz. gold, 150 oz. silver, and 18 to 35% bismuth.

Salt Lake County

The South Utah mines at Newhouse have been shut down. The mill was stopped in April, and some high-grade ore was sent to the Tooele smelter in May and June, yielding 120,921 lb. copper, 2197 oz. silver, and 29 oz. gold. In the first four months the yield was 1,290,063 lb. copper.——A 50-ton flotation plant is to be tried at the Ohio mill at Lark.

On September 7 fire destroyed part of the mill and the transformer station of the Wasatch Mines Co. at Alta. The loss is estimated at $40,000, but the plant will be rebuilt.——On September 9 fire destroyed about $90,000 of apparatus of the Dykes Universal Concentrator Manufacturing Co. of Salt Lake City. The Company was engaged in distilling, concentrating, and solidifying wood alcohol, which was placed on the market in the form of small cubes and packed in tin cans. H. K. Clover, chemist of the Company, stated that the apparatus in the laboratory was imported from Germany, Belgium, and Bohemia, and could not be replaced until after the war. All tanks, stills, and pipes in the laboratory were of pure copper and brass, some of them alloyed with platinum, and one large still was about 75% silver. The carboys, test tubes, and graduates were of finest Bohemian glass. In addition to the apparatus, the loss included wood alcohol in tanks and a supply of valuable chemicals, and furniture, cans, and bottles used in packing the product.

The South Hecla Mining Co., of Alta, held its annual meeting last week. The daily output is now 30 tons of ore, but during the summer it was 100 tons per day.

Summit County

Shipments of Park City products in August totaled 4355 tons, of which the Silver King Coalition contributed 2455 tons; Silver King Consolidated, 1157 tons; Daly-Judge, 476 tons; and Daly West, 170 tons. Good progress is being made with the new Daly West mill.

Bournonite, a sulphide of lead, copper, and antimony; jamesonite, a sulphide of lead and antimony; and calamine, a silicate of zinc, occur in certain mines at Park City, according to Frank Robertson Van Horn in the August *Bulletin* of the A. I. M. E. The failure to recognize bournonite is due to its similarity to tetrahedrite. It is a rare mineral, and has been found in the Silver King Coalition and Daly West mines, from the 1300 and 1000 to 1200-ft. levels. Jamesonite is also rare, and occurs in the Silver King Coalition and Daly-Judge mines. Calamine has never been reported from Park City before, where it was identified on a dump at the Quincy mine, associated with a brownish manganese oxide resembling wad.

CANADA

Ontario

(Special Correspondence.)—The Ontario government has issued an 'order-in-council' granting an extension of time for three months for the performance of assessment work on mining claims, in view of high prices and the difficulty of obtaining money.

Toronto, September 1.

It is reported that all of the silver bullion in the wrecked steamer *Empress of Ireland* has been recovered by divers.——After three weeks of work at one-third capacity, the Casey-Cobalt company will bring this up to about 70%, and 10 drills will be at work in the mine.

The Nipissing Mines Co. has taken an option on 1,501,000 shares of the McIntyre company, of Porcupine, at 40c. per share, or $600,400. The Company has 60 days from September 7 to examine the property and decide on its acquisition. ——The Vipond mill at Schumacher is in full operation.——The Rea mine at South Porcupine produced 1000 oz. gold in July, and is employing from 35 to 40 men.——During the period ended August 12 the Hollinger mill treated 16,456 tons of ore averaging $15.46 per ton, with 94.4% recovery. Total costs of mining, treatment, etc., were $4.17 per ton, and the profit was $171,976. The net surplus is now $481,135. The mine continues to show good results. A winze is being sunk below the 675-ft. level. On this level the vein is 20 ft. wide, assaying $10.90 per ton.

Mineral production of this province for the first half of 1914 is as follows:

Product.	Quantity.	Value.	First half 1913.
Gold, ounces	99,869	$2,011,069	2,171,147
Silver ounces	13,379,044	7,053,418	7,693,713
Copper, tons	8,357	1,197,059	832,645
Nickel, tons	13,105	2,872,843	2,514,414
Iron ore, tons	47,160	118,119	141,324
Pig iron, tons	343,408	4,429,664	5,051,840
Cobalt, tons	129	22,581	7,374
Cobalt and nickel oxide, lb.	757,268	379,152	186,317

Yukon

The eighteenth anniversary of the discovery of gold on Bonanza creek was celebrated at Dawson on August 17. Rain somewhat interfered with the program. With the estimate of $5,400,000 for the current season, the total gold shipments from the Klondike since 1885 amount to $179,853,908. The Klondike gold today comes chiefly from Bonanza, Eldorado, Hunker, Dominion, Gold Run, Last Chance, Quartz and Sulphur creeks, and benches along some of the streams. The Fortymile, Sixtymile, Stewart, Scroggie, Livingstone, Nansen and other districts contribute a share. There were 5310 placer claims in good standing in the Yukon Territory at the end of March 1914, of which 4428 were in the Dawson district. There were also 908 quartz claims, 554 being at Dawson, 152 at Duncan, 25 at Whitehorse, and 81 at Conrad.

PERSONAL

T. J. Hoover is in New York.

L. D. Ricketts has gone to Arizona.

Donald F. Irvin has gone to New York.

F. G. Cottrell has returned from Denver.

D. T. Day was in San Francisco this week.

W. Y. Westerfelt was in San Francisco Thursday.

E. H. Leslie has gone to Salt Lake City and Denver.

Frank Dennis is in New York, returning from London.

W. R. Calvert was in San Francisco returning from Calgary.

Ralph Arnold will leave New York shortly for Venezuela.

Colin Fraser has been examining properties in New Guinea.

Edwin J. Collins, mining engineer of Duluth, was in Los Angeles on business last week.

Walter Harvey Weed, mining geologist, was recently in Boise, Idaho, on professional business, en route home from Alaska. He was expected in New York on September 15.

W. E. Colby addressed a joint meeting of the San Francisco sections of the A. I. M. E. and the M. & M. Soc. Amer., at the Engineers' Club, Monday evening, on the Argonaut-Kennedy Extension litigation.

Olof Zetterlund, general manager for El Arco Mines Co., San Bartiolo, Copala, Sinaloa, Mexico, was in San Francisco this week on his way to New York. He plans to purchase additional equipment for a cyanide plant.

Archer W. Hendrick, of Portland, Oregon, has been elected president of the University of Nevada to succeed the late J. E. Stubbs. Mr. Hendrick was formerly dean and professor of English at Whitman College, Walla Walla, Washington.

J. B. Tyrrell, of Toronto, has recently been making an examination of the lower part of the valley of the Fraser river in British Columbia with the object of determining the question of the existence or non-existence of oil in commercial quantities.

Charles H. Lee, consulting engineer for Los Angeles, has been engaged by the ground water division, water resources branch, of the U. S. Geological Survey, to carry on comprehensive investigations of ground water supply throughout the Pacific slope of San Diego county. Mr. Lee will maintain his engineering offices in the Central building, Los Angeles, where he will continue his consulting engineering practice

Obituary

H. C. Gerber died at Los Angeles on August 9, after a long illness. He was a well known mining man and at the time of his death was vice-president and general manager for the Yaqui River Smelting & Refining Co. His death will be regretted by his many friends.

Henry Bratnober, who died at Livermore, California, September 13, was born 65 years ago in Prussia. He was educated in that country, but came to the United States before the Civil War, in which he served with distinction among the Northern troops. He was one of the pioneer mining men of the West, being especially connected with the influx of British capital in Western metal mines that marked the eighties. His judgment and his word ranked high in London, and he was the responsible agent in the selection of many of the best properties bought by the English. Later he turned his attention to Alaska, in which he was much interested at the time of his death. He was an active worker to the last, and an indefatigable traveler who went at the first hint of a discovery, to see things for himself. It was characteristic that he should have been interested in the Chisana, a district that is only being proved this year. A big, jovial, friendly man, a hard worker, and an excellent judge of mines and prospects, he will be much missed.

James B. Haggin is another of the pioneer mining men of America whose death has just been announced. His name is so closely interwoven with big mining, both in North and South America, that it is difficult to decide where to begin in describing his activities. He was born in Kentucky in 1827 and educated for the legal profession. In fact he practised law at St. Joseph, Missouri, and Natchez, Mississippi, until 1849, when he joined the throng moving to California. Here he did well, and both in California and Nevada he became a power. Later, in Montana, with Daly he founded what has become the Anaconda Mining Co., just as elsewhere with Hearst he started great enterprises. In recent years his greatest work has been in connection with the Cerro de Pasco, that great Peruvian enterprise to which he devoted so much time, money, and energy. To the general public he was best known as the owner and breeder of race horses, and in this as in mining he scored a success worthy of his Kentucky ancestry. However, Haggin was no man to be dominated even by a pleasure, and he suddenly sold all his turf holdings when he found them taking too large a part in his life. Right to his death he was active, and in the troublesome days of the money panic in 1907, as we recorded at the time, his eighty years did not prevent his daily attendance at the conferences of the capitalists who stopped the panic. He was a vigorous, keen witted, far seeing pioneer—the sort that marked the old generation, but the like of which present conditions do not conspicuously develop. Under his care big enterprises grew and many men worked because of his faith in the future.

The death of Albert Grothe, better known to his numerous Mexican confrères as Don Alberto, on August 19, at the age of 73 years, in the American hospital at Mexico City, marks the passing from Mexico's mining circle of its 'grand old man.' Everyone familiar with the modern development of the metallurgy of silver in Mexico, which may be said to have commenced with the introduction of the cyanide process, will associate this advance with Mr. Grothe's work; and those of us who have known him and sat at the tea table in his offices and enjoyed his congenial companionship for a half-hour during the balmy afternoons of the Mexican winter, feel the loss of a true friend.

As a mill builder and metallurgist, whose work in Mexico was largely responsible for the introduction of the Pachuca tank and other standard equipment in the present metallurgical practice, Mr. Grothe, despite his advancing years, has always been in the forefront. In addition to his professional duties and his representation of the Cyanide Plant Supply Co. of London and the Don Machinery Co., Mr. Grothe found time to devote to the establishment and upbuilding of the Mexican Institute of Mining and Metallurgy. As its first president, to which office he was repeatedly elected, Mr. Grothe was the corner-stone upon which this organization was built.

During the last few years of his life, Mr. Grothe devoted considerable time, in coöperation with the Department de Fomento in the preparation of a monograph on Mexico's mineral resources. Several installments of this work have been published by the Mexican government, and those who have read these detailed descriptions, written in the Spanish language, will appreciate what was to have been the monumental character of this work. We trust that this series, which was so well begun, may be completed. Mr. Grothe's many contributions to scientific societies and the technical press will be recalled as important and timely.

Of German parentage, his years spent in Mexico, his masterful command of Spanish, his intimate knowledge of the Mexican people, his broad technical experience, and his lovable personality gained for him the confidence and esteem of all those with whom he came in contact in that cosmopolitan country.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, September 17.

Antimony	15 —15¾
Electrolytic copper	14 —14¼
Pig lead	4.15— 5.10
Quicksilver (flask)	$75
Tin	36 —37½
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	15

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 17.—The copper situation is unchanged, and lead and spelter are quiet at 3.85 and 5.25c. per pound respectively. Antimony ranges from 10 to 13c.; three shipments have arrived. Ferro-manganese is $85 to $100 per ton. Platinum, $48 to $50 for soft, and $52 to $54 for hard metal. As stated last week, the general feeling in copper is much better, despite failure of negotiations for a pool. Consumption both at home and in England has held up better than was anticipated.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	58.73	....

In New York and London, prices have been around 55c. and 24 to 25d. per ounce respectively. The market is stronger now, and the increase in supplies in New York seems to be met by the purchases for coinage in various countries. Practically all sales are on a cash basis, and there has been no business for future delivery. Owing to a favorable season and low stocks at Bombay, resumption of silver shipments to India from London is likely soon.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per pound more. Prices are in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	....
Mch.	14.72	14.11	Sept.	16.23	....

May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

Transactions in this metal have been few, and quotes of 12.15 to 12.60c. per pound are the same as last week. Copper production of the Braden mine in August was 4,532,000 lb., a record, from 80,895 tons of ore with 72.70% recovery, against 1,332,000 lb. in July, and 662,000 lb. in June. A clean-up in August gave the large return. The Old Dominion yielded 2,236,000 lb., against 2,962,000 lb. in July; Shannon, 1,960,000 lb., against 1,084,000 lb.; and Granby, 2,714,089 lb. in July. Output of the Sulitjelma mine, Norway, increases, that for August being 1100 tons of concentrate.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Sept. 10	3.85	Aug. 5	3.85
" 11	3.85	" 12	3.85

June	4.33	3.90	Dec.	4.02	....

Lead ore prices at Joplin, Missouri, are dull at $46 per ton, basis of 80% metal.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Aug. 20	No quotes	Sept. 3	75.00-85.00
" 27	80.00	" 10	75.00

Advice from London states that the British government has secured all supplies of quicksilver in England for war purposes. It is allowing a certain amount to be sent to some South African mines. Indications are that prices are likely to appreciate instead of declining. New York quotes are $75 per flask.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

At Joplin a month ago blende of 60% metallic zinc was selling for $38 to $40 per ton. After a smart rise to $50, basis, which figure was paid for virtually the entire production of an entire week, or approximately 5000 tons, bids for ore dropped quickly, declining to $45, at which figure the market is fairly steady. The decline after the unnatural advance was to be expected. An increase of $10 per ton was recorded during a period of two weeks, this being the sharpest gain in the history of the local industry. The strength was purely speculative; future strength will doubtless be based upon something more substantial, and there seems little doubt that an ultimate advance may be looked for. Zinc metal, which reached $6 at East St. Louis, declined to $5.75 per 100 lb. at the close of August. For the corresponding week of 1913 blende brought $46 to $48 per ton, basis, with premium lots commanding as high as $51. Spelter was quoted at $5.75.

ZINC DUST

There have been sales as low as 15c. per pound, while other dealers quote from 17½ to 25c. A small shipment reached San Francisco during the week, but was immediately sent away to Central America. Another lot is expected within a month.

TIN

Nominal prices are now about 32c. per pound. A shipment of 725 tons is due in New York next week, which surprised the trade. Tin-plate scrap is accumulating, as Germany used to absorb the most of it.

COMPANY REPORTS

The following companies operate at Reefton, on the west coast of the South Island of New Zealand, and the reports cover the year 1913. A. Winter Evans is general manager for the whole group.

BLACKWATER MINES, LIMITED

Development consisted of 1648 ft. of driving at $13.04 per foot, 314 ft. of cross-cutting at $7.56 per foot, and 1768 ft. of raising at $14 per foot. Crediting ore won during this work, the net average cost was $10.02 per foot. Driving 918 ft. on the lode averaged $10.84 per ton over 17 in. Of this, 420 ft. exposed $14.35 ore over 24 in., and 498 ft. $4.23 ore over 11 in. Raising 1188 ft. showed 22 in. of $12.56 ore, of which 812 ft. opened 25 in. of $14.83 ore, and 376 ft. 15 in. of $4.37 ore. Stoping was done on No. 1 to 5 levels, inclusive, but No. 1 to 3 are about exhausted. Ore reserves are estimated as 104,727 tons averaging $9.89 per ton over a stoping width of 31.98 in., a small increase over 1912. Prospecting was carried out on several other claims. Geological work covered the correlating various strike and dip faults frequently found in the mine, to avoid unnecessary work being done. The main shaft must be sunk farther. The mill treated 45,053 tons of ore for £75,072 by amalgamation, £7152 by cyanidation, and £4841 from 462 tons of concentrate, equal to a total of $9.28 per ton. Total recovery was 84.19%. More Wilfley tables have been since installed to save more concentrate and increase the recovery. Costs were as follows: mining, $350 (high on account of narrow lode and other factors); transport and treatment, 85c.; general, 62c.; and bullion charges, 12c., a total of $5.09 per ton. The gross revenue was £83,239; gross profit, £34,982; and net profit £21,526, of which £12,500 paid No. 6 dividend.

CONSOLIDATED GOLD FIELDS OF NEW ZEALAND, LTD.

This Company operates the Wealth of Nations mine, and has large interests in the Blackwater and Progress mines in the same district. Development in the Company's mine totaled 2579 ft., at an average net cost of $8.94 per foot. Driving on the lode showed 35 in. of $10.59 ore for 133 ft., and 37 in. of $3.98 ore for 131 ft. In raising, 258 ft. showed 49 in. of $11.98 ore, and 142 ft. of $2.16 ore over 31 in. Stoping cost $2.02 per ton. Ore reserves are 25,764 tons assaying $10.41 per ton; but the peculiarities of the lode and gold content make estimates difficult. Geological work was limited on account of extra work in the survey department. The mill treated 23,661 tons for £28,355 by amalgamation, £8730 by cyanidation, and £681 from 152 tons of concentrate, total recovery being 78.89%. But this will be increased to 87.75% on complete slime treatment. Treatment costs were $1.14 per ton, and total costs $4.62 per ton. Total revenue for the year was £43,801; gross profit, £18,457; and net profit, £6056.

PROGRESS MINES OF NEW ZEALAND, LTD.

The area of this Company's property is 816 acres, five miles from Reefton. Underground work in 1913 totaled 4055 ft., at an average net cost of $8.60 per foot, of which 633 was diamond-drilling, costing $3.38 per foot. In driving 42 ft. there was exposed 58 in. of $15.07 ore, and 51 in. of $1.87 ore for 538 ft. In raising 428 ft. the lode was worth $2.17 over 59 in. Cross-cutting showed 169 in. of $15.63 ore for 16 ft., and 182 in. of $1.21 ore for 104 ft. Reserves cannot be estimated, but stopes on levels No. 6, 9, 10, and 11 should yield from 42,000 to 60,000 tons. Prospecting was done on outside claims, and some geological work was done in the main mine. Mining cost $3.06 per ton. The mill treated 34,996 tons yielding £26,878; £10,217 from sand, and £4619 from concentrate.

MINERAL STATISTICS

The following for 1913 is from the U. S. Geological Survey: Georgia ranked secind among all the states in 1913 in the production of barytes, bauxite, fuller's earth, natural mineral paints, and paper clay, and was the only state reporting a production of asbestos. The total value of the mineral products of Georgia in 1913 was $6,525,792, a fair increase over 1912, nearly 80% of which was from its clay pits and quarries. Clay products were valued at $2,692,619; granite and marble, $2,105,366; coal, 255,626 tons, worth $361,319; ochre, 11,869 tons, worth $123,616.

Coal mined in Illinois in 1913 amounted to 61,618,744 short tons, valued at $70,313,605, according to figures compiled by E. W. Parker, in coöperation with the Illinois State Geological Survey. The coal-mining industry presented some interesting and contradictory features. In the first place, the diminished supply of natural gas in Kansas caused an increased demand for Illinois coal in the territory which is naturally tributary to the Illinois coalfields but which for a few years had been supplied by gas, and during the last three months of the year the strike in the coalfields of Colorado caused a movement of Illinois coal to more western markets in order to supply the deficiency created by the strike. On the other hand, exceptionally mild weather in the early winter had a depressing influence on the domestic trade and the water-power developed by the Keokuk dam seriously affected the demand for and prices of steam coal within a radius of 250 miles from the power-plant. It is estimated that the power furnished by the dam displaces about 3000 tons of coal per day. The resultant effect of all these influences was an increase in the quantity of coal produced from 59,885,226 short tons in 1912 to 61,618,744 tons in 1913, a gain of 1,733,518 tons, whereas the value showed an increase of only $19,267, the average value per ton declining from $1.17 in 1912 to $1.14 in 1913.

Texas, the largest of all the states in area and fifth in the number of inhabitants, ranks nineteenth in the value of its mineral production. In each of the last two years Texas advanced two numbers in the rank of mineral-producing states. In the percentage of its increase in 1913 over 1912, Texas was exceeded by only one other state, its northern neighbor, Oklahoma, which, on account of the sharp advance in the price of petroleum, showed a gain in value of mineral products of nearly 50%, while Texas showed an increase in value of 38.9%—from $22,797,015 in 1912 to $31,666,910 in 1913. Texas ranks second in the production of asphalt and third in the production of quicksilver. Since the great strike at Beaumont in 1901, petroleum has had first place in the mineral products of the state, and Texas now ranks fourth in the quantity of petroleum produced and seventh with respect to the value of the product. The production increased from 11,735,057 bbl. valued at $8,852,713, in 1912, to 15,099,478 bbl. valued at $14,675,593, in 1913. The possibilities for oil development are widely scattered over Texas, and the chances for further extension are therefore excellent. Second in importance among the mineral products of Texas, reckoned by the value of output, is coal, including lignite or brown coal, the combined production of which amounted in 1913 to 2,429,144 short tons valued at $4,288,920, against 2,188,612 short tons valued at $3,655,744 in 1912. Texas is the only state in the Union that produces considerable quantities of both bituminous coal and true lignite or brown coal. The only other mineral products of Texas which contribute as much as $1,000,000 to the total value are asphalt, cement, clay, and natural gas, cement being $2,663,063, and natural gas $2,073,823, against $2,064,124 and $1,405,077 in 1912, respectively.

RECENT PUBLICATIONS

Coal-Mining Practice in District II. By S. O. Andros. *Bulletin* 7. University of Illinois. P. 22, illustrated. Urbana, 1914.

Pre-Cambrian Geology of Southeastern Ontario. By Willet G. Miller and Cyril W. Knight. P. 151. Ill., maps, charts, index. Bureau of Mines, Toronto, 1914.

Safety Bulletin No. 13 of the National Founders' Association. P. 9, illustrated. Chicago, June 1914. Contains some useful hints on the use of hoisting accessories.

The Ohio Coal Supply and Its Exhaustion. By Frank A. Ray. *Bulletin* 12. Ohio State University. P. 46, Ill., maps, plans, charts, index. Estimates of the coal supply vary from 48 to 688 years, depending on weight given unknown factors.

Western Electric Poles. P. 12, illustrated. Western Electric Co., New York, 1914. A well prepared booklet with all details of cutting poles, inspecting them, and specifications of suitable poles for line work.

Statistical Report of Highway Work in North Carolina during 1912. Compiled by Joseph Hyde Pratt and Miss H. M. Berry. *Economic Paper* 36. North Carolina Geological and Economic Survey. P. 127. Illustrated. Raleigh, 1914.

The Broad-Top Coal Field of Huntingdon, Bedford, and Fulton Counties of Pennsylvania. By James H. Gardner. *Report* No. 10. Topographic and Geologic Survey of Pennsylvania. P. 81, ill., index. Also case with 11 maps and charts, and table of coal analyses. Harrisburg, 1913.

Building and Ornamental Stones of Canada. Volume II. Maritime provinces. By Wm. A. Parks. P. 264. Ill., map, 45 halftones and colored plates, index. Department of Mines, Ottawa, 1914. A valuable contribution on an important subject, and should be obtained by architects, builders, contractors, and others.

The Young Man and the Electrical Industry. By James H. Collins. P. 24, illustrated. The little book deals with the opportunities afforded a young man in this industry, and the different lines in which he may direct his activities, as exemplified by the works of the Westinghouse Electric Co., of East Pittsburgh.

United States Geological Survey publications, Washington, D. C., 1914:

Production of Magnesite. By Charles G. Yale and Hoyt S. Gale. P. 14.

Gold, Silver, and Copper in Alaska in 1913. Mines report by Alfred H. Brooks. P. 13.

Silver, Copper, Lead, and Zinc in the Central States in 1913. Mines report. By B. S. Butler and J. P. Dunlop. P. 93.

Marble Resources of the Juneau, Skagway, and Sitka Districts, Alaska. By Ernest F. Burchard. *Bulletin* 592-C. P. 13, map.

A Barite Deposit near Wrangell, Alaska. By Ernest F. Burchard. *Bulletin* 592-D. P. 9, Ill. This was reprinted in the *Press* of September 5.

Ore Deposits of Northeastern Washington. By Howland Bancroft. Including a chapter on 'The Republic Mining District,' by Waldemar Lindgren and Howland Bancroft. *Bulletin* 550. P. 215, Ill., maps, plans, index. An abstract of this work appeared in 'The Mining Summary' of September 12.

Contributions to *Economic Geology*:

Some Deposits of Mica in the United States. By Douglas B. Sterrett. *Bulletin* 580-F. P. 61, illustrated.

Gold Placers of Wind and Big Horn Rivers, Wyoming. By Frank C. Schrader. *Bulletin* 580-G. P 19, illustrated.

BOOK REVIEWS

Unit Construction Costs. By E. Horton Jones. P. 152. Illustrated. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price $2.

This valuable compilation was originally prepared for and presented at the Salt Lake meeting of the American Institute of Mining Engineers, held in August, and has already appeared in the July *Bulletin* of the society. An abstract with line drawing was published in the 'Concentrates' of the *Press* of August 8. The costs given are probably the most detailed of any yet published on construction of a plant, and represent expenditure on the new smelter of the Arizona Copper Co., Ltd., operating at Clifton, Arizona. The data covers the period from February 1912 to February 1914, and the total cost was $2,105,020. This volume will be found extremely useful to constructing engineers.

Quantitative Chemical Analysis. Introductory notes on. By Charles William Foulk. P. 250. Illustrated, index. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price $2.

This is the third enlarged and revised edition of the little work first appearing in 1898, and again in 1910. No claim of originality is made for the aim of the work, namely, the presentation of beginning work in quantitative analysis in such a way that a student will be led to think more of the general aspects of the subject, than of learning merely to carry out a succession of methods. Part I starts with advice to students, then notes on chemical apparatus, weighing, gravimetric analysis, samples, precipitation, filtration, volumetric analysis, normal solutions, and titration. And Part II covers the preparation and standardization of volumetric solutions, and various determinations. Everything is given in a practical manner, and students and others should find the volume of general value.

The Diamond Fields of Southern Africa. By Percy Albert Wagner. P. 347. Ill., map, plans. *The Transvaal Leader*, Johannesburg, Transvaal, 1914. For sale by the *Mining and Scientific Press*. Price $8.

Although diamonds are a luxury, and are of little use save for personal adornment, yet their recovery, cutting, and destination is of considerable interest. The estimated production of this form of carbon in 1913 was worth £14,815,400, of which the Union of South Africa yielded £11,246,200; German Southwest Africa, £2,953,500; Rhodesia, £3200; Belgian Congo, £12,500; and other countries, £600,000. The British Empire produces 76% of the total. The author of this volume has for years personally studied the whole subject of diamonds. The geology of diamond deposits, and the origin of the stones, is not settled, and it is doubtful whether a general accepted theory will be found. In an editorial paragraph of the *Press* on April 4, 1914, was given in abstract the views of Gardner F. Williams, so long at Kimberley. Mr. Wagner discusses the kimberlite and other occurrences. The diamond 'pipes' are of peculiar shape, but contain all the stones within their respective areas. Early and present systems of mining are described at Kimberley, the Premier, and other properties of less note. Also crushing, concentrating the 'blue' and 'yellow' ground, and saving the diamonds on grease tables. Alluvial mines are also described, and a few remarks on the economics of the industry. The book is well illustrated, has a good bibliography, but lacks an index. It is a valuable addition to the literature on all pertaining to these gems.

RECENT PATENTS

1,100,972.—Electrical Furnace for the Reduction of Copper and Other Ores. William H. Hampton, New York, assignor to the Conley Electric Furnace Co., Inc., Wilmington, Delaware, a corporation of Delaware.

A copper reduction furnace comprising a plurality of shafts having electrical resistance heaters in their walls, an upper shaft portion common to said shafts, and electrical resistance heaters in the walls of said common shafts portion.

1,100,582.—Process of Crushing and Grinding Calcium Carbide. Walter S. Landis, Niagara Falls, Ontario, Canada, assignor to American Cyanamid Co., Nashville, Tennessee, a corporation of Maine.

Preventing explosions as well as lessening the weathering of calcium carbide and the losses incident thereto during the process of grinding said carbide which consists in carrying out the grinding operations in an atmosphere of substantially chemically pure nitrogen, substantially as described.

1,106,332.—Percussive Drill. John George Leyner. Denver, Colorado.

In a fluid operated drill, a drill cylinder and a piston therein having a drill rod projecting forwardly thereof, said drill rod having a fluid conveying bore, a front head on said drill cylinder, a fluid pump cylinder, secured to the front head, a piston in said fluid pump having a rod secured to said drill rod, and fluid connections for conveying fluid from said pump to said drill rod bore.

1,106,836.—Process and Apparatus for the Extraction of Pregnant Cyanide Solutions from Pulp. Edson S. Pettis, San Francisco, California.

Combination of a tank, means for introducing and distributing pulp into the top portion of the tank, means for simultaneously introducing into the tank a counter underflow of barren solution, yet allowing the solids to gravitate continuously and thicken in the solution underflow, and means for recovering the pregnant solution, mixed solution, and thickened pulp separately, substantially as described.

1,107,240.—Process of Treating Ore. Niels C. Christensen, Jr., and Theodore P. Holt, Salt Lake City, Utah, said Christensen, assignor to George H. Dern, Salt Lake City, Utah.

A process of treating ore, consisting in preliminarily finely dividing the ore and bringing finely divided fuel into intimate mixture therewith and adding chemicals to the mixture of fuel and ore according to the results desired from the subsequent treatment of the ore, igniting the fuel carried by a charge of the preliminarily prepared ore and roasting the charge by internal combustion thereof, and thereafter extracting the useful metals from the roasted ore by lixiviation with a suitable solvent.

1,106,333.—Gyratory Crusher. John McInrue, Chicago Heights, Illinois, assignor to Chalmers & Williams, Inc., Chicago Heights, Illinois, a corporation of Illinois.

The combination of a gyratory shaft and a crusher head, said shaft and head being provided with engaging tapered surfaces, and means for securing and maintaining the bearing on said head in strong frictional engagement with the bearing on said shaft, said means comprising right-hand and left-hand nuts threaded to said shaft, both of which bear upon the upper end of said crusher head, and means for connecting said nuts to said head whereby angular movement of said head on the crusher shaft will be imparted to said nuts, substantially as described.

INDUSTRIAL PROGRESS

Pan Motion Concentration

The application of the miner's pan motion to modern concentrating machinery is marked by the presentation of the Senn concentrating machine. Pan motion has been experimented with by the inventor of this new mechanical motion for a number of years, and the present machine is claimed to have overcome all the early mechanical difficulties and a machine has been perfected which embodies this motion.

The motion is the result of two eccentrics operating at right angles and connected by a ball and socket joint. The perfect circular pan motion can be varied to an elliptical motion by changing the position of the eccentrics. The machine has a double cone belt drive, belt tightener, shifter, and feed clutch connected to a worm gear by means of a telescope knuckle shaft. This permits the operator to change the belt travel instantly by either the hand wheel or lever.

In the construction of the machine all bearings are babbitted, pins in all drum-heads are standard cold rolled shafting and interchangeable on short notice. The stationary frame supporting the whole machine consists of four massive columns or pedestals, which are bolted to two heavy timbers. The columns on their upper ends are braced firmly together both side and endwise by heavy pipes and rods. The main drive shaft rests in large bearings at the base of the columns, which eliminates vibration from the machine. The machine has been designed for heavy use and large tonnage. The idea of the pan has been carried out in the construction of the belts, which has molded into it thousands of small disc shaped indentations. Whether the material treated is coarse or fine, classified or unclassified, it is claimed that due to the uniform pan motion the mineral settles almost immediately and the gangue is held in suspension and carried in successive half circular steps down the incline of the belt and discharged as tailing.

A careful test on low-grade copper ores of Arizona, continued through several months, resulted in favor of the pan motion concentrator. The concentrator is manufactured by the Senn Concentrating Co., of San Francisco, California, which company also maintains an ore-testing laboratory in Oakland, California, for the demonstration of its machine.

Commercial Paragraphs

The Swedish Metal Preserver Co., M. W. Putnam, Pacific building, San Francisco, agent, has issued a pamphlet on its metal preserver.

The Holt Manufacturing Co., Stockton, California, in the August number of the *Caterpillar Times* discusses with illustrations some of the many uses to which the caterpillar type of tractor is adapted.

The Chas. C. Moore & Co., Engineers, San Francisco, report the sale of a 6½ by 15 Platt triplex pump direct connected to 150-hp. motor, and two 6-in. 5-stage Platt pumps direct connected to 125-hp. motor, to Goldfields Merger Co. The triplex pump operates against 1525-ft. head and is the first centrifugal mine pump to be used in that district.

The Busch-Sulzer Bros.-Diesel Engine Co., St. Louis, Missouri, will be pleased to distribute to those who are interested a reprint of an address by Dr. Diesel before the American Society of Mechanical Engineers on 'The Present Status of the Diesel Engine in Europe,' and a few reminiscences of the pioneer work in America. The Pacific coast sales division of this Company is in the Rialto building, San Francisco, California.

DEATH of T. J. Grier, manager for the Homestake Gold Mining Company, is announced. Mr. Grier passed away suddenly after a pleasant evening with Mr. Edward H. Clark at Los Angeles. We shall speak later of his services to the industry: now we mourn the passing of a friend. It is a pleasure to have recorded recently the fine tribute paid to him by the Commission on Industrial Relations at its hearing at Lead.

CYANIDE conditions in the United States and Mexico are likely to improve rapidly, thanks in large part to the persistent efforts of Mr. Charles Butters, who has been bringing pressure to bear at Berlin to secure a lifting of the embargo on shipments. On Wednesday this week he received the following wire from the acting secretary of state, Mr. Robert Lansing: "Advices from Berlin state that the American minister was informed on the 16th instant by the director of the Gold and Silber Scheide Anstalt that export of cyanide is now permitted for America and Mexico. Imperative that no cyanide be re-exported." This means that shipments must be for *bona fide* use in this country and Mexico. Since the German ports are still open to neutral ships and the routes through Holland and Denmark are open, there is no reason why direct importations should not be resumed. In addition, three of the fourteen sets of machinery ordered in Germany before the war for use in converting cyanamid into cyanide, are reported ready and can be gotten out. There is furthermore a large shipment of cyanide from Germany to the United States that had got as far as Antwerp when the trouble began. This may become available at any time, though it may also be diverted or destroyed. If, therefore, users will but be patient and accommodate each other a little with loans, there need be no real hardship.

REPORTS of rich gold discoveries in Alaska are made from time to time, but rarely is any more heard of them, and mining men wonder from what sources the reports emanate. Such wild exaggerations have greatly held back the development of this promising territory. The recently widely published news that a goldfield of enormous extent and possibilities had been discovered in the Broad Pass district of Alaska, and credited as coming from Mr. Stephen Birch, is a report without any foundation whatever, as we noted in our news columns last week. The details are given in our New York letter. A spirit of over enterprise led some of our contemporaries to spread the news ridiculously beyond what proved to be its deserts. The real responsibility, however, rests with the one starting the report. People who give out news of this sort should be apprehended and taught a lesson, as they cause a rush to the alleged district, and subsequent disappointment to miners who have enough hardships in Alaska. It might be as well to point out that great deposits such as at Juneau and at other great lode mines, are not developed in a few days, but after many years of skilful work; so that when a report is heralded that a goldfield equal or larger than some other one which has been a long period in coming to production is discovered, caution should be exercised in accepting the statement, at least among technical men.

PROGRESS IN ZINC SMELTING

In closing the series of articles on modern zinc smelters in the Middle West, by Mr. Leslie, with the description of the Nassau plant of the Mineral Point Zinc Company, we take advantage of the occasion to contradict the often expressed opinion, especially by those whose endeavors have been confined to other fields of metallurgical practice, that zinc smelting has been marking time for the past thirty years. A study of the situation presents ample evidence to the contrary. The opinion is generally based upon the fact that no really successful substitute in the form of a blast-furnace has been found for the present retort furnaces. It has been tried innumerable times, and a review of the literature on the subject and the files of the Patent Office will show that no little effort by most capable scientists has been directed toward producing a substitute for the present retort method of zinc distillation, all of which efforts to date have been failures in a greater or less degree. When mixed with a large percentage of the products of combustion and air, an inherent difficulty in blast-furnace practice, zinc will not condense to fluid metal, an oxidizing of the vapor taking place with the formation of zinc oxide and a fine metallic powder. A solution for this and other difficulties has been sought, and is being sought, but with little hope of success for the moment. Electric smelting of zinc at present occupies the attention of the zinc metallurgist, but it remains to be demonstrated just what the pos-

sibilities of electricity as applied to zinc smelting are. While the thermal efficiency of zinc smelting continues low, and fuel costs are high, this is true also of railway locomotives and steamships. In fact wherever it is necessary to burn coal, oil, or gas under boilers or in furnaces for whatsoever purpose it may be, high thermal efficiencies are impossible. Recognizing the impossibility of this situation and that heat will go up the chimney, radiate, and migrate uselessly, the tendency in all of the industries has been to conserve it as much as possible and reduce operating costs by increased mechanical efficiency. Zinc smelting has been no exception, and improvements in this industry are keeping pace with the advances in thermology in the other industries. In time, perhaps direct smelting will prove possible, but in the meanwhile it must be evident to anyone who has attentively read these articles, that rapid progress is being made in many other phases of the work and that the total efficiency, which after all is the significant measure, has increased enormously in the past decade and is still increasing. It is only to the outsider that zinc smelting looks backward.

TIN IN THE UNITED STATES

The tin consumption of the United States is large, over a hundred million pounds, worth about forty cents per pound, being imported yearly. Most of this is used in the making of tin plate, which is chiefly used to make cans for holding oil and preserved vegetables and meats. Many years ago the tin plate was imported, but most engineers remember the part which tin plate played in national politics a quarter century ago, and how, with the aid of a protective tariff, the making of tin plate has been transferred to this country, only the pig tin being imported. All efforts to secure supplies of tin within this country have been uniformly unsuccessful, for although the metal is found in many places, at none does it occur in sufficient amounts to be capable of being worked at a profit. The Harney's Peak fiasco is well known to most engineers. In Alaska some tin has been recovered by dredging, and the industry has there developed local importance, but it is actually inconsiderable, the annual yield being less than one-tenth of one per cent of the total imports. Some years ago the Standard Oil Company, one of the largest users of tin cans, thought to provide itself with an independent supply of tin and thereby obtain better rates from the plate manufacturers. The sources of ore supply were therefore investigated, and it was found that tin concentrate from the Malay States could be carried to New York at a low rate by the Standard Oil steamers, which ordinarily returned empty from those waters. A tin-smelting plant was therefore built near the refinery at Bayonne, on New York bay, at a cost of about $300,000, and work was started. The local smelters in the Malay States were naturally disturbed by this interference with their business and made representations to the local government, with such success that a prohibitive export tax was laid on shipments of tin concentrate. This unexpected blow made it impossible to smelt concentrate at New York in competition with the Orient and England. Since that period, Bolivia has become a considerable shipper of tin concentrate, which goes to Europe for smelting, but the result of the Standard Oil venture seems to have effectually deterred anyone else from embarking in the tin-smelting business in this country.

Since the useful life of tin cans is exceedingly short, it would seem that it should be possible to recover the tin from old cans and re-use it. This would at first appear true from the fact that the production of secondary tin from tin-bearing material in this country usually amounts to a little over one-fourth of the yearly imports. On closer inquiry, however, it is seen that this secondary tin is chiefly derived from tin scrap made in the manufacture of tin cans, from tin foil, and from old tin pipe. Most of the tin in empty cans is a total loss, as but a small part of the total yearly output of cans is ever reworked. The reason for this is that the cost of recovering the tin from tin scrap is so high that there is but little profit in the business, and it is not possible to go to much expense in collecting old tins and preparing them for detinning. The discovery of a cheap process for the recovery of tin from scrap would add a good deal to the wealth of this country by giving more employment to domestic labor and freeing us from the necessity of buying so much tin abroad.

Since the war in Europe has cut off shipments of tin to the United States and caused the price of the metal to increase rapidly, much interest has been exhibited in the proposal to divert the shipments of Bolivian concentrate to this country for smelting. The situation has materially changed since the unfortunate venture mentioned above. At that time the tin output of Bolivia was small; now it is valued at about $25,000,000 annually, or about two-thirds of our yearly imports. The concentrate is now being shipped from the port of Mollendo to Hamburg or Liverpool *via* Magellan, a distance of about 10,000 miles, for smelting. Now that the Panama canal is open, shipments can make the short cut, reducing the distance to 7000 miles. The distance to New York is, however, only 4000 miles, and as smelting costs here should closely approximate those in Europe, it should be perfectly feasible to transfer the industry to the vicinity of New York or Baltimore. The tin deposits of Bolivia are peculiar in that the cassiterite occurs in veins, instead of in placer deposits. The deposits occur between Lake Titicaca and Lake Poopo, the richest deposits being 30 miles south of Oruro. The veins are narrow and have not yet been worked to any great depth, the deepest mine being less than 700 feet. The tin content averages about 3 per cent, and the ore is concentrated to 60 per cent before shipping. Nearly one-half of the total output is derived from the mines owned by Don Simón Patiño, though the Compañia Estañifera de Llallagua, which, by the way, is under

direction of an American technical staff, produces about 15,000 quintals per month, and is one of the most important tin lode mines in the world.

The following figures (of which we were unable to determine the original source), showing the charges which a ton of 60 per cent tin concentrate must bear, will be of interest in this connection:

Mining	$ 4.78
Sorting	0.48
Melting	1.51

Freight, mine to Guigui	35.88
" Guigui to Mollendo	10.14
" Mollendo to Europe	7.80
Export duty	15.60
Commissions, Insurance	10.92
Total	$87.47

It will be seen from these that the margin in favor of the United States is not so great as might at first appear, for a freight rate of $7.80 per ton to Europe *via* Magellan affords no great leeway for a cheaper rate to New York. Assuming the same rate per thousand miles this would correspond to $5.88 per ton to Hamburg *via* Panama, and $4.42 to New York, assuming that the American ships also have to pay $1.20 per ton canal dues. This gives New York an advantage of $1.46 per ton of concentrate, or $2.40 per ton of tin, which offers possibilities, assuming that smelting costs here will not exceed those abroad. It is also quite possible that the next Republican congress could be persuaded to place an import duty on pig tin if any appreciable domestic smelting industry develops in the meanwhile. All in all, it seems quite probable that one effect of this war will be to develop a domestic tin smelting industry, though the fact that the tin mines in Bolivia are largely financed with European capital is likely to have a good deal of bearing on the matter.

WAR EFFECTS IN AUSTRALASIA

Mail advices from Australasia indicate that up to the last week of August the effect of the war had not been so great as was expected. All of the gold mines are working. Broken Hill, the great centre of lead, silver, and zinc production, employing over 9000 men with 42,000 people directly dependent on them, has been hit the hardest. Some of the smaller mines were closed, others are working half, and some full time. Production of zinc concentrate by flotation has been largely curtailed. Mt. Morgan in Queensland, and Mt. Lyell in Tasmania, continue their full copper production, but Wallaroo and Moonta and others have shut down. At the Great Cobar work was already temporarily reduced, so there was less change. In Tasmania, the government proposes to advance certain sums for tin, copper, lead, and zinc ores, the balance to be paid later, but the terms are not everywhere acceptable. New Zealand yields few metals of importance save gold and silver.

In Australia the population of approximately 5,000,000 people produces much more of minerals, metals, and agricultural material than it consumes. The country also has not many metal industries, so markets are widely scattered in Africa, Asia, England, Europe, and the United States, but mainly in England and Europe. The war has shut off the greater part of these outlets for products, consequently Australia and New Zealand are suffering. Exports and imports of all materials from the Commonwealth are about balanced at £79,000,000 each per year, and on a total debt of about £300,000,000, the annual interest charge is nearly £10,000,000. Exports of gold and silver amount to £11,000,000 per year, depending on the trade balance. New Zealand's trade is £22,000,000 of exports. The mineral output of Australia is valued at £25,000,000 per year, to which gold contributes £10,000,000; silver, £1,750,000; copper, £3,250,000; lead, £2,000,000; zinc, £2,000,000; tin, £650,000; and many rare ores, also a large tonnage of coal.

Regarding the effect of the war on the metal output, it may be said that the mints at Perth, Melbourne, and Sydney can easily handle the output of precious metals, of both Australia and New Zealand. Copper is exported to England and Europe, and a good deal is returned in the shape of manufactured goods, as is also true of other metals. A larger tonnage of lead is sold in China and Japan than most people think. Zinc ore and concentrate is mostly sent to Belgium and Germany. It amounts to over 500,000 tons per year, and contains up to 45 per cent metal. The export of spelter to other than England is prohibited now. Tin eventually goes to England and the United States. As for rare ores, the destination of which is generally Europe, there is no market.

It would seem that after the metal companies accumulate considerable stocks, paying operating charges meanwhile, they will begin to feel embarrassed, unless exports can be made regularly to the allied countries now fighting. There is little use in sending copper and lead to the United States, as these metals are produced far in excess of consumption here already. Fortunately Australia has one large pig-iron plant working, and another under construction. No quicksilver is produced, and as its exportation from England is prohibited, the gold mines will be short. Zinc dust is not used, and the rolling of sheet zinc is still an infant industry. Cyanide is imported from Glasgow, but the Scotch people have stated that they can take care of Africa and Australia. The wool shearing season is now on, and Germany takes 20 per cent of the clip in normal times. The finances of the country are sound, though stock exchanges are closed as elsewhere. There is considerable patriotic feeling over the war, and as a result of its record and its defence scheme, which made Australia prepared for the war, the Labor party defeated the Liberals by large majorities in the election for the House and Senate of the federal parliament on September 5. The Labor party, let it be noted, is a much more responsible party than in the United States and comes into office with experience as well as authority.

As War Looks in London*

By T. A. RICKARD

Speaking of naturalization, I learn that the ordinary naturalization of a German or Austrian in England is in effect only a sort of declaration of intention, for he does not cease to be a subject of the Kaiser or the Emperor unless he obtains a formal release of allegiance, which is reluctantly accorded. If of an age proper for military service, he would be treated as a deserter, for his failure to respond to the call to arms, whenever he returned to the country of his nativity. On the English passport given to a German who has been 'naturalized' here in the ordinary (and incomplete) way, it is stated that the passport is granted "with the qualification, that he shall not, when within the limits of the foreign state of which he was a subject previously to his obtaining his certificate of naturalization, be deemed to be a British subject unless he has ceased to be a subject of that state in pursuance thereof or in pursuance of a treaty to that effect." If one of your people takes out his papers of naturalization, your government relinquishes him, and you metaphorically spit at him, don't you? This question comes round to the old one: Can a leopard change his spots? Only by going from one spot to the other, or, to speak seriously, by imbibing the ideas of his new country. The ability to speak the language is, to my mind, the best proof of assimilation. But it is not a complete proof, for a good linguist may learn quickly and still retain the 'spots,' while a man who speaks with a strong guttural accent may be perfectly loyal to the country of his adoption.

That reminds me. The Krupp machinery firm gave an Ullrich separator to the Bessemer Memorial laboratory at the Royal School of Mines. The same firm made a contract with the Dunderland Iron Ore Co., a British company operating in Norway, to deliver a number of these machines—and obtained a payment in advance. A couple of days ago Charles McDermid, the secretary of the Institution of Mining and Metallurgy, received a telephone call asking that the separator at South Kensington might be loaned to Krupp's agent in London, in order to copy it or make drawings suitable for such a purpose. He referred his caller to the authorities at South Kensington. The Rector of the Imperial College and Royal School of Mines, Sir Alfred Keogh, is at the front, being a Medical Corps reservist. It is not likely that the request will be granted, but unpleasant remarks have been made. The Krupp machinery works at Magdeburg are separate from the Krupp armament establishment at Essen, but both belong to the same great firm, and the armament firms have been largely instrumental in exciting military aggression. My point is this: the Krupp machinery (not armament) agent in London is W. Stamm. He is an Englishman by naturalization; more than this, his son fought and died for the Union Jack in South Africa. That is good enough for me; the man that gives his son's life or his own for the country of his adoption is naturalized indeed.

London, August 28.

"Business as usual pending alterations to the map of Europe." That is the motto of all who still have something to do. We are sending a circular to all the advertisers in *The Mining Magazine*, urging them that this is their chance to win new business and to get even with the German firms whose undercutting has been the feature of recent competition. I hear of seven or eight big machinery orders that were placed in Germany and are now canceled by the war, and of a general campaign to take the business lost to the enemy by the stifling of his commerce. That silent victory has been won by our fleet. During the last few days our papers have been full of data concerning various industries directly affected by the war. Among the matters under discussion is the manufacture of cyanide and the smelting of zinc. You will be glad to learn that arrangements have been made in England for all the cyanide required in the Transvaal, and that the greatest goldfield is assured also of all the other supplies needed to continue regular operations.

London, August 29.

In an earlier letter I mentioned that an Englishman, John Cockerill, founded an important steel industry at Liége. I note that it is now reported that the Prussians have taken hold of the gun factory at Cockerill, at Seraing, close to Liége, and are using it for the manufacture of war material. The Belgian artisans have been offered a 50% increase in wages and work under the threat of being shot for any bungling, such as patriotism might reasonably suggest.

London, September 9.

HOW IT AFFECTS A SIBERIAN MINE

C. W. Purington writes us from Nadezhdinsky, in the Bodaibo region of Siberia, where he is looking after the interests of the Lena Goldfields: "Just now the question is, will we ever get back. They drew off 1800 men here yesterday (August 2) out of 8000 for the Army mobilization, and although we do not have the pleasure of getting the veracious news disseminated by the *Chronicle* and other papers, it seems there must be something doing. The war is some distance from here, but it may last some time, and cause a low period in Russian mining activities."

*In this series of war letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies, but he will endeavor to be as impartial as he may. We add this week an extract from a friend in Russia, and we hope later to pass on to our readers comment from friends in other countries concerned in the fighting.

Tin Mining in the Federated Malay States

By E. J. VALLENTINE

With a steady annual output from 40,000 to 50,000 tons of the most valuable of the base metals, the Federated Malay States maintains its place at the head of the tin-producing countries of the world. However, it is only within the past few years that the general public has begun to realize the wealth of this far-off British protectorate. It is curious to reflect that the rubber boom of 1910 did far more to advertise the country than the production, year after year, of half the world's tin.

The reason for this is not far to seek. Most of the cassiterite is won from extensive alluvial deposits lying at comparatively shallow depths from the surface, which can be exploited without much capital outlay. These ideal conditions for the poor man gradually attracted a large number of Chinese miners, and they were well established in the country before the advent of British protection over 30 years ago. Under a beneficent government the industry has since grown and flourished, but it has remained almost entirely in Chinese hands, and it is only of late years that European and Australian mining capital has been largely introduced.

The output for 1913 was 50,127 tons of metallic tin, of which the Chinese produced over 42,000 tons or 85%, leaving 15%, or under 8000 tons, to the credit of the European or Australian owned mines. The following table gives the F. M. S. outputs for the past 14 years:

Year.	Tons, metal.	Year.	Tons, metal.
1900	42,444	1907	48,431
1901	46,145	1908	50,837
1902	46,480	1909	48,743
1903	49,978	1910	43,863
1904	50,960	1911	44,149
1905	50,992	1912	48,421
1906	48,618	1913	50,127

In the early days, transport and other difficulties combined to restrict mining to the high-grade parts of the known deposits; but as time went on these difficulties gradually lessened, operating costs came down, the price of the metal rose, and so more and more ground became available for profitable exploitation. Alarmist rumors have been current of late that the principal deposits are rapidly becoming worked out, and this is certainly true of the high-grade portions of the known fields, while it is also the case that the chance of discovering a new alluvial field of any considerable extent is very remote. Many lodes may still be found, but lode mining will never produce on a scale sufficient to offset a serious decline in alluvial mining. Deep leads of tin-bearing gravel occur in several localities under 'false bottoms' of what seemed to the earlier miners to be 'kong' or 'bedrock,' and they are now being discovered from time to time by drilling, but they do not seem to be sufficiently numerous or extensive to make much difference to the total output.

The 'Gondwana' beds of the Kinta valley said by the government geologists to be of glacial origin,* are of considerable economic importance, and should yield large returns for many years. However, there is apparently little doubt that the tin-mining future of the F. M. S. chiefly depends on the extensive areas of alluvium carrying one pound or less of cassiterite per cubic yard, which are so situated that they can only be worked on a large scale, with a suitable choice of modern methods, and which, as yet, have received comparatively little attention. Owing to the heavy initial expenditure necessary for the development of these areas, one may assume that their exploitation will rest more in European than in Chinese hands.

Introducing Machinery

The Chinese are gradually becoming more willing to employ machinery, or water under pressure due to natural head, in cases where the advantages are very obvious, but they are conservative to the core and very distrustful of any innovation. Unfortunately, the record of European mining in the F. M. S. is not a list of unbroken successes. Several elaborate plants, hurriedly selected and erected in the full conviction that they would eclipse Chinese methods, have been shut down after a few months' run, and these failures have done much to foster the Asiatic distrust of our modern mining appliances. However, small steam boilers with pulsometer pumps or portable engines driving centrifugal pumps are in common use in Chinese mines, while, within the past year or two, small gravel pumps of the Kershaw type have come into favor, the 8-in. being the usual size. Steam winches are used for hauling cars out of many of the larger open-cast mines, and power-driven puddlers are often employed where the tin ore is found in stiff clay.

The European and Australian owned mines show many different methods of working. Several companies are operating lodes on fairly conventional lines, at costs ranging from 7s. to over 23s. per ton milled. A few large open-cast mines are operating alluvial beds much after the style affected by the Chinese, their working costs running from about 1s.3d. per cubic yard upward. The heavy rainfall makes pumping a considerable item of expenditure and more especially at limestone and granite contacts where a mine forms a sump for a large drainage area.

A number of hydraulic mines are operating ground with a general slope sufficient to carry off the tailing cut from the bank by the monitors. Some of them claim to work at under 2d. per cubic yard and to win their black

*Quart. Jour. Geol. Surv., Vol. LXVIII, p. 140, 'The Gopeng Beds of Kinta,' by J. B. Scrivenor.

tin for £20 per ton. Where the tailing has to be raised, other hydraulic concerns are using monitors in conjunction with elevators. Although the mechanical efficiency of these hydraulic elevators is very low, they prove most economical where a good supply of water under natural pressure is obtainable, the operating cost in some instances being under 4d. per cubic yard. They have so widened the scope of hydraulic mining that practically all the available streams within reasonable distance have been, or are being, harnessed.

Where the supply of water under natural pressure is limited and the tailing has to be elevated, a monitor may be operated in conjunction with a power-driven gravel pump. The operating cost, which depends largely on the height the gravel has to be lifted, may be in the neighborhood of 5d. per cubic yard. This brings us to what is often called a suction plant, where power is used both to pump water through a monitor and to operate a gravel pump. Assemble this plant on a pontoon, and we have the suction dredge, which has been boomed as the ideal equipment for working alluvium resting on bedrock of limestone. A hard crystalline limestone underlies large areas of the tinfields and gives a most irregular bottom, high pinnacles alternating with deep pockets. However, none of the mines operating these dredges have as yet proved very successful. It is claimed that under favorable conditions the working cost is about 6d. per cubic yard, but the more usual cost in the F. M. S. would seem to be nearer double that figure. One company is operating at a profit in a limestone bottom with a large bucket dredge which is provided with a gravel pump for cleaning out the pockets; but owing to the depth of water in the pond it is difficult to say whether the pump does its work thoroughly.

The Opportunity for Bucket Dredges

It is only recently that the possibilities of bucket dredging in the F. M. S. have received serious attention. A great future for this method of mining, which should show to best advantage in the large areas of swamp land known to contain tin, but hitherto classed as unprofitable, may be predicted. In a deposit of a free gravelly nature, resting on a level soft bottom, an operating cost (including administration, head office, and general expense) of 4½d. per cubic yard may be quoted. For several large bucket dredges now being built for service in the F. M. S., an engineer with considerable local and Australian experience estimates the operating cost under 5d. per cubic yard. The cost of a dredge, afloat in the pond and ready to work, is given as £20,000, the duty as over 80,000 cu. yd. per month, and the life of the plant as 20 to 25 years.

With regard to the operating costs quoted in this article, one must state that they do not include the tin duty, which is deducted direct from the selling price of the output. Most of the tin ore won in the F. M. S. is sold locally to representatives of one or other of the smelting companies, who deduct the duty when buying, and pay it to the Customs when they export the ore to their smelting works at the coast. It is calculated on a sliding scale based on the ruling price in local currency and there is a fairly heavy tax, as the following table will serve to show:

Price per ton metal.	Duty per ton metal.			Duty per ton ore.*			Ratio of duty to value.
£	£	s.	d.	£	s.	d.	Per cent.
140	16	13	2½	11	13	3	11.90
150	18	5	10½	12	16	1¼	12.20
160	19	18	6½	13	18	11¾	12.46
170	21	11	2½	15	1	10	12.68
180	23	3	10½	16	4	8½	12.89
190	24	16	6½	17	7	7	13.07
200	26	15	8¾	18	15	0¼	13.39
210	28	8	4¾	19	17	10½	13.53
220	30	1	0¾	21	0	9	13.66
230	31	13	8¾	22	3	7¼	13.78

*Assessed for duty as containing 70% metallic tin.

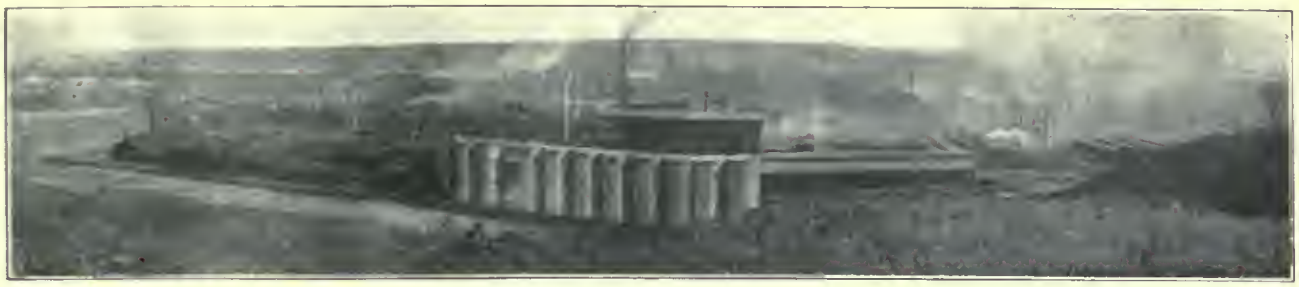
The duty collected on the output for 1913 was £1,238,326. In the case of a mine recovering one pound of cassiterite per cubic yard, with tin at £180 per ton, it amounts to 1¾d. per cubic yard.

Prices and Production

As regards the future scale of production from the F. M. S., it is hardly necessary to say that it depends more on the price of tin than on any other factor. The high prices which have ruled for the past three years have encouraged miners to work low-grade ground and re-wash old dumps, the result being these increased annual outputs which would seem to give the lie to any suspicion of rapid exhaustion of the fields. But what would happen if the price were to fall to £140 per ton?

It is not so long ago that £140 was considered a good price, and, in 1908 or 1909, no one would have dreamed of opening up a mine that did not promise to produce at a profit on that basis; but many of the mines now in operation require to market their tin at £160 or £170 in order to pay their way. The principal Chinese mine owners (and one must not forget that 85% of the total output is won by Chinese) are agreed that should the price drop to £140 per ton and remain at that level for several months, the result would be the biggest slump ever known in local mining. As far as can be gathered, there is no reason to fear that the price will come down so low, but it is instructive to learn the margin on which much of the Chinese mining is being conducted. The F. M. S. produces nearly half the world's tin, and it would therefore seem reasonable to suppose that, if over production should ever cause a glut of tin in the market and a serious fall in price, the decline in output from the Chinese mines alone should soon reduce the world's stock sufficiently to bring the price back to, say, £160 per ton.

In the Federated Malay States is an attractive field for the mining investor, and, should the numerous dredging and other recently floated companies have anything like the success they anticipate, a substantial influx of European and Australian capital can be expected. It is to be regretted that the enormous profits won from the tinfields of a British protectorate have been going mostly into Chinese pockets for so many years.



GENERAL VIEW OF NASSAU PLANT; CONCRETE STORAGE BINS IN FOREGROUND.

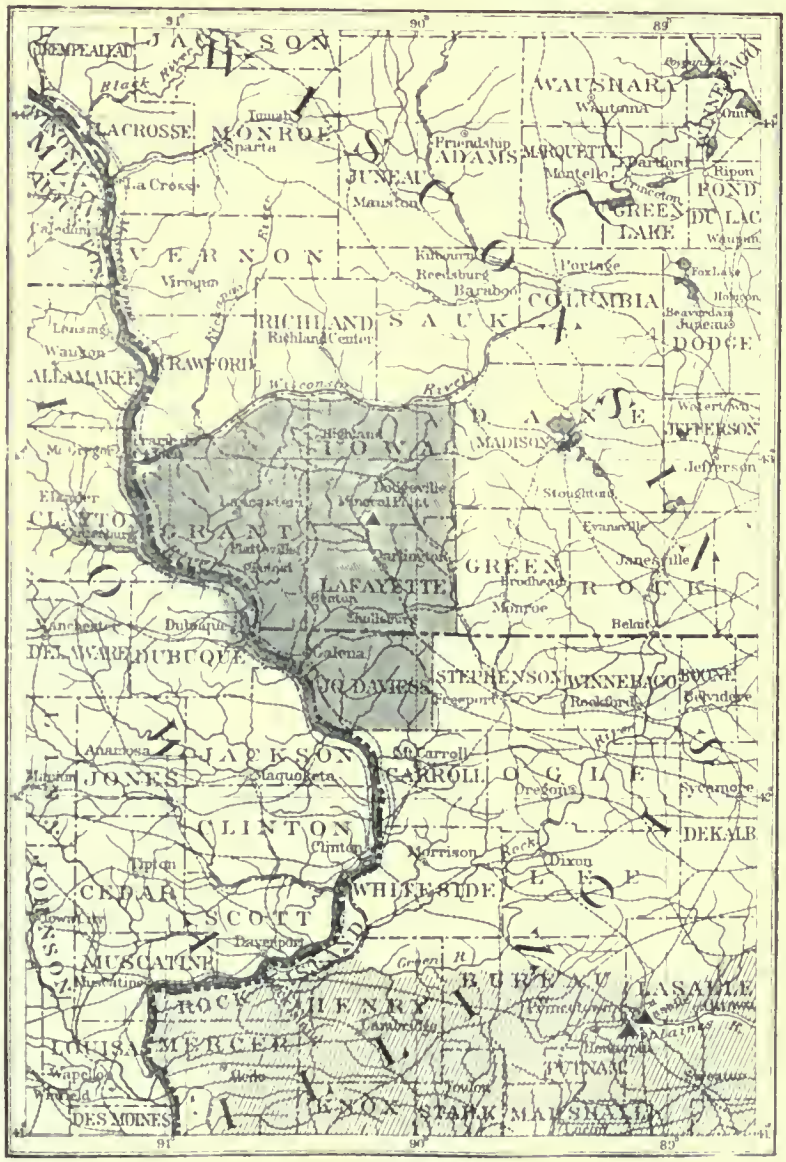
The Nassau Zinc Works at Depue, Illinois

By E. H. LESLIE

Northern Illinois has long been identified with the zinc smelting industry, and by reason of its central situation with relation to mines, market, and fuel, bids fair to be a district productive of spelter for many years to come. The Illinois coalfields have for many years been identified with the zinc industry and in that it has been the history of the industry that zinc concentrate has been shipped to the fuel rather than the fuel being shipped to the concentrate, the coalfields of Illinois will continue to be the centre of spelter production as long as coal is mined and zinc concentrate produced in the Middle West. The Nassau plant at Depue is the most modern of that series of northern Illinois zinc smelters which include the classic Matthiessen & Hegeler plant at La Salle, which was the scene of so many developments and improvements in the metallurgy of zinc, and the Illinois Zinc Co.'s smelter at Peru. The Matthiessen & Hegeler Zinc Co. is operating 5256 retorts, with a new block under construction, and the Illinois Zinc Co. has 4640 retorts. Both of these plants employ the chamber process of sulphuric acid manufacture and the smelting equipment is supplemented in both cases with sheet-zinc mills, in which a large part of the spelter output is rolled into various forms for different industrial purposes.

The Nassau works, at Depue, Illinois, is the most modern of this group and the largest American zinc smelter. The contact process of sulphuric acid manufacture is a distinctive feature of the works, and the general practice is representative of the most modern work in the smelting of zinc concentrates. The mechanical efficieney of the plant has been carefully studied, with the result that the handling of supplies and products and the movement of concentrate through the plant has been made as nearly automatic as modern equipment permits.

The smelter site is a level tract of land covering approximately 80 acres which is adjacent to the main right-of-way of the Rock Island railway, 110 miles west



RELATIONS OF ZINC SMELTERS IN THE NORTHERN ILLINOIS COALFIELD TO WISCONSIN ZINC MINES AND TO TRANSPORTATION. DEPUE IS IN THE LA SALLE DISTRICT.

DRYING AND CRUSHING DEPARTMENT; CONCRETE STORAGE BINS AT THE LEFT; 'HIGH LINE' RAILWAY BETWEEN BUILDINGS.

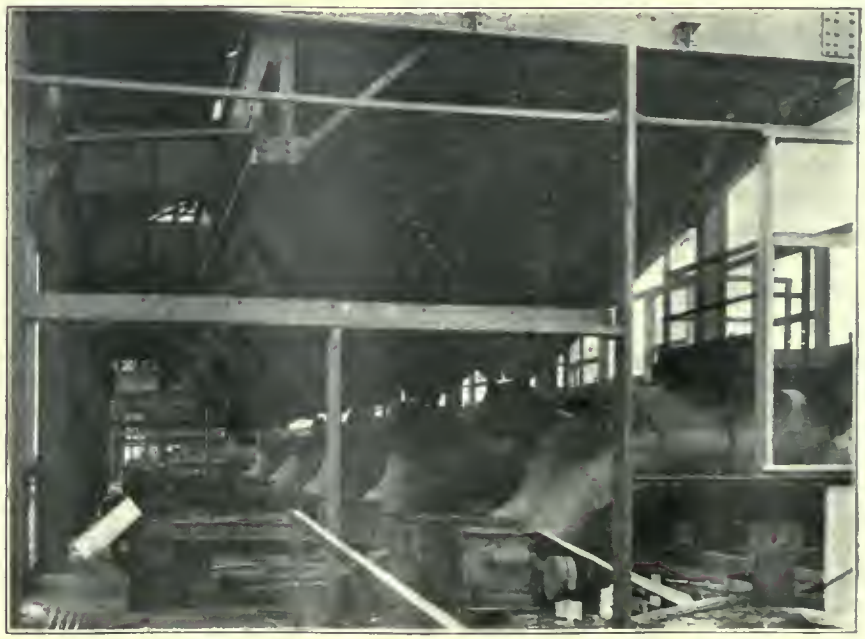
of Chicago and about 150 miles from Platteville and the Wisconsin zinc district. Its advantage in position with relation to ores, fuel, and market is readily recognized and where freight rates on raw materials is an important item the influence of position on economic smelter practice is a most important item. The lay-out of the smelter site, position of buildings, and tramways has resulted in a plant of excellent distances for the economic conduct of smelting operations. The accompanying illustrations present an idea as to the character of the smelter construction. The structural steel, concrete, brick, and corrugated iron structural materials are evidence of a construction which is not dependent upon an uncertain fuel supply, but has that stamp of permanency which marks the new producer-gas smelters.

Construction work on the Nassau plant was begun in the autumn of 1904, the original plant consisting of the three distillation furnaces in the concrete furnace building and two roasting furnaces, with the accompanying acid plant, and the pottery, mix house, crusher, power plant, office, and laboratory. This plant was put into operation in the summer of 1906 and subsequently the capacity was gradually increased until in 1910 it was double that of the original plant. About two years ago construction was started on a large addition which again doubled the capacity of the plant and brought it up to its present size.

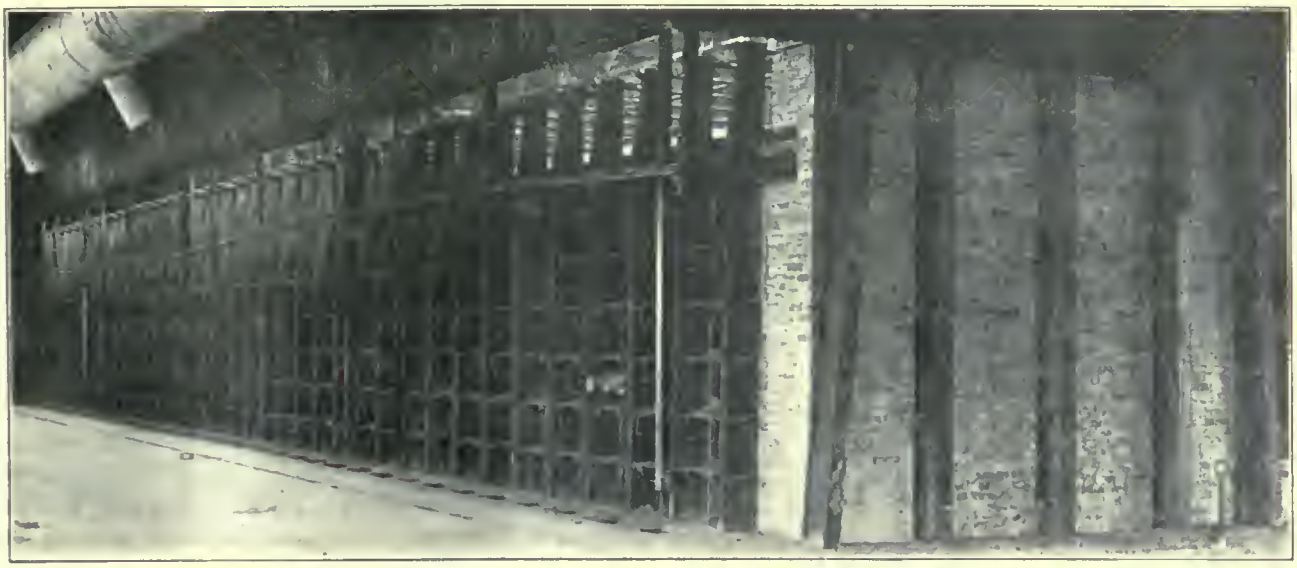
The concentrates from the Wisconsin mines which form a large part of the material treated, together with concentrates from Missouri, Colorado, and other western states, are brought over a turn-out from the main line to the smelter and delivered at the drying and crushing plant. The sulphide and carbonate ores as received at the plant are handled separately, each being stored in a separate unit of the drying and storage department. The sulphides after being received are unloaded by a mechanical unloader, elevated and fed through a rotary dryer. Here the moisture is reduced to 0.3% and the dried product is passed through a pair of rolls and thence to a ¼-in. trommel, the oversize being passed through a second set of rolls and returned to the screen. The undersize as discharged from the screen falls upon a belt-conveyor and is elevated to the circular concrete storage bins. There are 10 of these bins, which have a large capacity, with additional steel hopper bins of about one-half the concrete bins capacity.

The carbonate ore as received at the smelter is unloaded by a mechanical unloader and crushed to ¼ inch in a Farrell jaw crusher and elevated to a feed-bin over a rotary, which has a capacity of 150 tons per 10 hours. After being dried, during which the moisture in the concentrate is reduced to below one per cent, the dried concentrate is recrushed in a pair of 36 by 16-in. rolls and elevated to a ¼-in. trommel screen, the oversize from which is returned to a pair of 27 by 14-in. rolls and subsequently returned to the trommel. The undersize from the trommel is conducted by a system of three conveyor-belts to the circular concrete storage bins, previously mentioned, and elevated in bucket-elevators to the bins. The drying and crushing department of the plant is not in continuous operation, being only used as occasion demands. The entire drying and crushing department is driven by one motor of 75 horse-power.

The dried concentrate is drawn from the bottom of the circular concrete storage bins, previously mentioned, and removed by a belt conveyor to the hoppers which



GAS PRODUCER PLANT FOR DISTILLATION FURNACES.



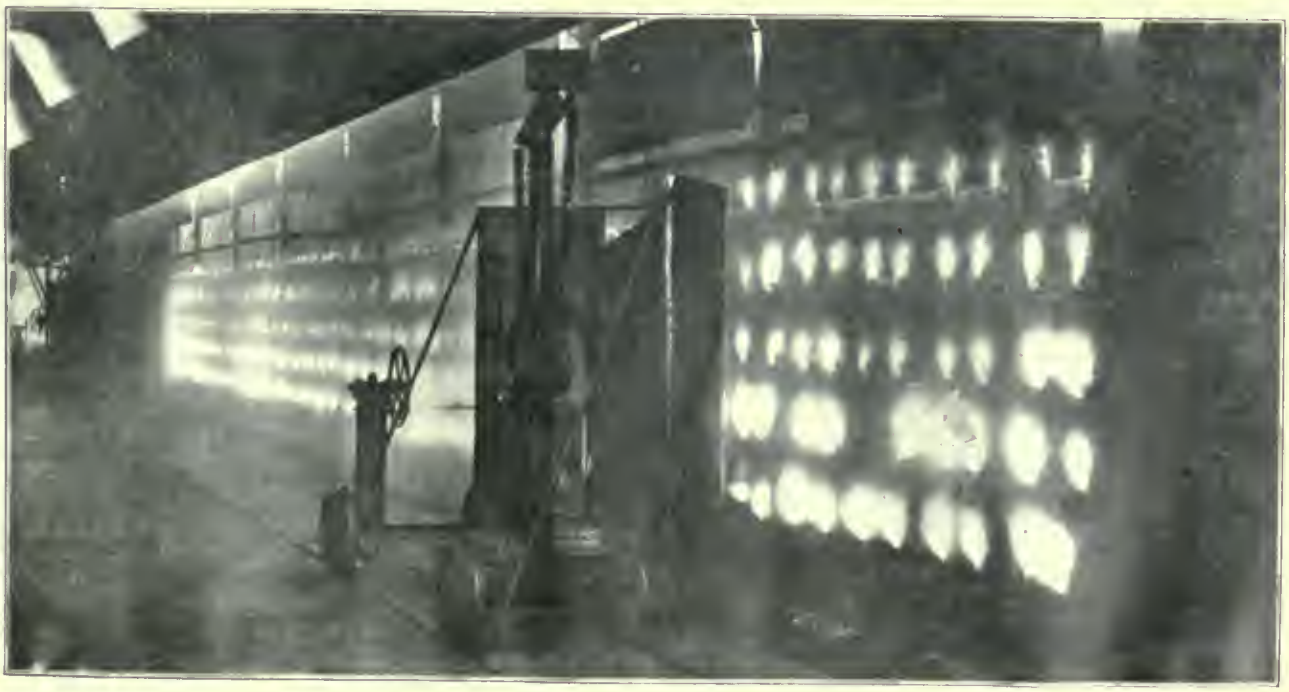
DISTILLATION FURNACES, SHOWING FRAME FOR RETORTS.

load the industrial cars for delivery to the roasting furnaces. As filled, the cars are distributed over elevated tracks, locally known as the 'high-line.' A gasoline locomotive is used on the 'high-line' railway for pulling cars to the different roasting houses, where they are automatically dumped into the feed hoppers of the roasting furnaces.

The roasting of the sulphide ores at this smelter, as at others where the furnace gases are utilized in the manufacture of sulphuric acid, is conducted in modified Matthiessen & Hegeler roasting furnaces. There are seven of these furnaces in operation at the Nassau works, four of which are arranged in one series and three in the other. The furnaces are separately housed in buildings of structural steel and corrugated iron.

The Hegeler roasting furnaces have seven super-imposed muffled hearths, which are 6 ft. wide and 80 ft. long, and of the same general type discussed in previous articles. The fuel, which is producer gas, is admitted under the lower three hearths. Heavy 'I' beam buck stays are used for bracing. The producer gas fuel for six of the furnaces is generated at one central producer plant which is equipped with 12 hand-poked producers and the gas generated is conducted through separate concrete underground conduits to the different roasting furnaces. Samples of the gas are taken every hour and analyzed for CO and CO_2. The southern Illinois coal which is used in the producers is delivered at the plant in standard hopper-bottom gondola cars and unloaded by gravity into bins on a level with the working.

The ore enters at opposite ends of the top hearths of the roasting furnaces and is drawn through the furnaces



DISTILLATION FURNACES WITH DRAW-CAR IN PLACE.

by means of the characteristic Hegeler rabbling mechanism, which has been described in a previous article. The concentrate, as charged into the roasting furnaces, contains 34% sulphur. Its passage through the furnace requires 60 hours, during which time the sulphur content is reduced to about one-half of one per cent. The temperature of the hearths varies from 1000°C. in the lower hearths to 850°C. in the upper. The furnaces have chisel platforms on either side which are fitted with a motor for elevating and lowering them, but are moved over tracks at the sides of the furnaces by hand. The 'chiseling' of the different hearths, or the removal of agglomerated ore, is done about every three weeks by men standing upon the platform and working through the ports at the sides of the different hearths. The furnaces have been in operation for several years and are still in a good state of preservation, the hearths having in but few instances shown signs of weakening. The furnaces are rabbled and drawn every hour. The roasted ore as discharged from the furnace falls over 1-inch grizzlys by which means any agglomerated lumps are removed. The roasted product is then elevated by a chain and bucket-elevator to hoppers on the level of the 'high-line' railway. It is then discharged into industrial cars and removed to the steel storage bins at the mix-house. These bins are 'W' bottomed and have a storage capacity of 9000 tons.

The anthracite coal for use in the retorts is elevated from the cars by means of a Peck carrier to a screen placed above the bins. The fine is discharged into the bins, which are of the catenary design, and the coarse is crushed and returned. The coal from these bins, which have a capacity of 250 tons, is drawn into industrial cars and removed to the mixing house. The cars of roasted sulphide, carbonate, and coal as they enter the mixing house pass over scales where they are weighed and the ore dumped into a Ransom concrete mixer. As the material is discharged from the mixer it falls into the boot of a bucket-elevator and is elevated to hoppers which discharge into the furnace charge cars, which have a capacity of 15,000 lb. each.

Distillation Furnaces

The retort or distillation furnaces are housed in four buildings, three of which are corrugated iron and one of reinforced concrete. The concrete building was the first to be built and this type of construction has since been abandoned. There are three blocks of furnaces, arranged in series in each of the four furnace buildings, making 12 blocks of furnaces in all. Each block of furnaces contains 750 retorts, giving the smelter a capacity of 9000 retorts. At present there are but 7500 retorts in operation. The furnace buildings are of the elevated floor type, the working floor being 22 ft. above the ground-level. This type of structure has come to be standard construction and adopted by all the modern smelters. In this furnace, which is of the Neureuther regenerative type, the gas and air are discharged through ports at three different levels in the centre wall. In this type of furnace, owing to the position of the ports, it has been necessary to construct a thicker centre wall than in the old Siemens furnace. The Neureuther type of regenerative furnace has come to be generally adopted in the more modern zinc smelters, the advantages claimed for it by the inventor being that by introducing the gas and air at different elevations in the centre wall a more uniform heating effect is obtained, an additional row of retorts may be installed, and a corresponding increase in capacity is possible. The air and gas enter through the checker-work under the floor of the combustion chamber and pass through the ports into the combustion chamber on one side of the centre wall, over the centre wall and out through the corresponding ports on the opposite side of the centre wall, thence through the checker-work on that side and on to the stack. The flow of air and gas is reversed regularly about every 20 minutes, causing the hot gases to heat the checker-work on the opposite side. The checker-work thus acting as a pre-heater of the gases conserves to a certain extent the heat losses and thereby increases the thermal efficiency of the furnace. While the principle of regenerative furnaces like the Hegeler muffle furnace is the same in every instance, the details of construction vary and each smelter superintendent and furnace man has original ideas as to what should be the proper construction.

Retorts Charged by Hand

The retorts are charged by hand, the charge mixture being brought to the furnace floor in the 15,000-lb. charge cars, from which it is shoveled into the retorts. The temperature of the distillation furnace is gradually raised from about 800°C. at the beginning to 1400° C. at the end of the shift. The draw-car used for drawing the retorts is hand propelled and the ladle operated by a hand winch. The retorts are drawn three times during the course of 24 hours, and scraped out with scrapers after the last draw. Water and steam are not used for the discharging of retorts. The plant treats about 200 tons of roasted ore per day.

The residue removed from the retorts falls into chutes, in the floor and immediately in front of the furnace, which connect with hoppers underneath and empty into large industrial cars of 6½ tons capacity. Two cars are used on each block, and the residue is removed by these cars to the dump. As the residue from the ores treated here is of no value, no effort is made to conserve it. Possibly at some time in the future a method will be devolved whereby the high carbon content of retort residue may be profitably reclaimed for its fuel value, but for the present most of the residue is dumped or used for railroad ballast.

There are two large batteries of gas producers for supplying fuel to the distillation furnaces. These batteries, of which one is made up of 14 mechanical producers and the other of 24 hand-poked producers, are placed between the furnace buildings. By this arrangement it is possible to have one battery of producers for

each two furnace buildings with their 6 blocks of furnaces.

The fuel used in the producers is southern Illinois coal, which is delivered at the plant in standard gondola cars and dumped into concrete bins situated under the tracks. From these bins the coal is elevated by means of a bucket-elevator, into a steel catenary bin, which is supported on structural steel columns from which the coal is subsequently drawn into an electric larry car and delivered to the bins of the producers. There is also stored a large quantity of coal on the storage piles. Locomotive cranes are used in handling this coal. The Brown hoist system of grab-buckets is used for unloading cars direct. The buckets travel suspended from a rail to the producer bins, where they are discharged. A 25-hp. motor is used for the operation of this crane.

Pottery

The clay or adobe used for pottery purposes is ground to ¼ inch in a gyratory crusher, from which it is removed to dry pans, a form of Chilean mill, where it is further reduced. As discharged from the dry pans, the crushed material is elevated to a wire cloth trommel, the undersize from which is discharged into the storage bins, while the oversize is returned and given a regrinding in the dry pan.

The clay or adobe used for pottery purposes is bins and given a weathering out of doors for six months at least, after which it is brought into the pottery and given a preliminary pugging in a Mehler pugging machine. It is then cut into a convenient size for handling as it comes from the pug-mill and again weathered for 15 days. The material is then removed from the stock piles and given a second pugging and elevated to the retort press floor. Here the material is placed in a Schlag machine and compressed into balls for the retort presses. The power for these machines is supplied by three individual 35-hp. motors.

The retorts are molded in Mehler hydraulic presses, there being two of these machines in the pottery department, one being held in reserve and to meet any increase in demand for retorts. The plant has a capacity of about 325 retorts per day at the present time. These retorts are 8½ in. inside diameter and from 48 to 56 in. long, according to their position in the furnace. As removed from the press, where they are molded under a pressure of 1000 lb. per square inch, the retorts are removed on trucks to the dry-rooms and stored for 60 days. The dry-rooms are arranged on 4 floors of the pottery building, there being 10 rooms on each floor with a storage capacity of 25,000 retorts. The rooms have both floors and ceilings of hollow tile and are kept at a temperature of about 60°C. by the exhaust steam from the power plant. The upper and lower floors are the finishing floors and the retorts are given their final drying here. A Vanetta machine is used for the manufacture of condensers. A 15-hp. motor is used to drive the condenser and ball machines. The material used for the manufacture of condensers consists of a mixture of one-half clay and the other a combination of ground retorts, old brick, and adobes. The condensers not being subjected to the intense heat of the furnace, do not require as good a grade of material or as much care in manufacture as the retorts. As removed from the augur machine they are allowed to stand for a day on the floor, then crimped and removed to the dry rooms, where they are stored for 15 days and subsequently removed to the tempering kilns for use in the furnaces. In removing the products of the pottery to the furnaces they are loaded on flat cars and drawn by a donkey engine over a track on the same level as furnace floors. The life of the retorts is about 35 days and the condensers 15 days.

GENERAL VIEW OF NASSAU PLANT; ACID STORAGE TANKS IN THE FOREGROUND.

Power Plant

The boiler plant consists of 8 boilers, 6 of which are of return tubular and 2 of water tube type. All the boilers are fitted with Green mechanical stokers. The principal power units consist of two Allis-Chalmers compound steam-engines direct connected to two 500-kw. Bullock generators. A third unit consists of a Nordberg compound engine driving a 500-kw. Westinghouse generator. The other engine-room equipment consists of condenser pumps, 3 service pumps, 2 high-pressure pumps for the retort presses, Ingersoll-Rand Imperial type air-compressor, and a Pawling and Harnischfeger

overhead electric crane. A Westinghouse panel switchboard with the regular meter and switch equipment is included.

The machine-shop, which is in the same building with the boiler and engine rooms, is fully equipped for performing all of the ordinary work in the operation of the smelter. All machinery is individual motor driven and includes 3 lathes, a planer, shaper, 2 drill-presses, 3 threading machines, Thermit welding outfit, and accessory equipment. The overhead electric crane is used for work in both the engine and machine shops. The blacksmith equipment includes 7 forges with accessories. The main smelter water-supply is obtained from the Illinois river, about one-half mile distant, by means of a 3500-gal. per minute centrifugal pump direct connected to a 150-hp. motor. The drinking water-supply is obtained from artesian wells.

The Acid Plant

The catalytic sulphuric acid plant for the utilization of roasting furnace gases at the Nassau smelter is unique and one of the features of the practice. It is to be regretted, however, that owing to the present status of the United States patent laws, that in many instances are more productive of litigation than protection, it is not possible to publish details regarding the operation of this process. I may say that the Grillo-Schroeder contact process is used. In this process the roaster gas, consisting of the sulphur dioxide resulting from the combustion of the sulphur from the ore, with the nitrogen and residual oxygen from the air, is carefully purified by the removal of both physical and chemical impurities. This is necessary to prevent deterioration of the contact mass. The purified gas is heated and passed through the converters, in which it comes in contact with the contact mass consisting of finely divided platinum distributed through a mass of granular, anhydrous magnesium sulphate. The catalytic action of the platinum causes the sulphur dioxide to combine with an additional atom of oxygen forming sulphur trioxide, or sulphuric anhydride. This is then absorbed in 98% sulphuric acid, the free water in the acid combining with the sulphur trioxide and forming sulphuric acid.

The principle of catalytic sulphuric acid manufacture is an old one, and is based upon the combination of sulphurous anhydride with oxygen in the formation of sulphuric anhydride which is easily absorbed in water, forming sulphuric acid. Finely divided platinum in the form of platinized magnesium sulphate has that faculty of condensing oxygen and facilitating the union of SO_2 with O into SO_3. By catalysis a decomposition and new combination is effected by reason of the presence of the platinum which does not enter into the reaction itself. It is believed by some that platinum does take part in the reaction, but is restored constantly to its original condition and as such in the cycle of operations no loss takes place. The temperature of the sulphurous anhydride at which it impinges upon the catalytic agent is important, as a complete oxidation with its corresponding high extraction is only possible within certain limits, about 375 to 425°C., at which temperatures a conversion of from 98 to 99° of the sulphurous to sulphuric anhydride is possible. Above this, decomposition takes place and the conversion is greatly decreased.

This process originated in Germany and has been developed in this country into a very efficient and satisfactory process. It has one great advantage over the older or chamber process, which is that it will, in one operation or by simple dilution with water, yield any grade of acid desired.

A great deal of attention is paid at this plant to accurate and scientific control of all operations. All ores, coal, and other raw materials are sampled by the most approved methods, and analyzed in a well equipped laboratory. In addition to the main laboratory, there are small departmental laboratories in connection with the spelter furnaces, roasting kilns, and acid plant in which intermediate and final products are analyzed as checks on the operation of the plant. The handling of materials, which is one of the principal features in operation of an efficient zinc smelter, has been given particular attention, with the result that the movement of supplies and products has been made as nearly automatic as modern equipment permits. For the comfort of the men the Company has supplied sanitary wash-rooms with lockers, mess-rooms, artesian wells, and other conveniences. The plant belongs to the more modern group of zinc smelters, and no little credit is due to the management for its most successful practice at America's largest zinc smelter.

In concluding the present series of articles on American zinc smelters, there is one suggestion which I would venture, and that is a closer coöperation of the zinc metallurgists.

There is no great secret about zinc smelting, and no one smelter, group of metallurgists, or any individual has a monopoly of all that is good practice in the industry, so why this unwillingness to give one's neighbor the benefit of one's experience and coöperate in every way possible for the good of the common cause? There are reasons, no doubt, for secrecy, but there are greater reasons for coöperation and publicity. It is a pleasure to note that among the most progressive and modern of the present-day operators this feeling of aversion to helping one's neighbor is disappearing and friendly relationships are being established. I would take occasion here to express my thanks to those whose assistance has made possible this series, and, while it is impossible to mention all, I recall with especial pleasure courtesies extended by Messrs. Archibald Jones, W. H. Gill, E. G. Godshalk, H. A. Grine, J. N. Houser, Elias S. Gatch, J. D. Martin, W. F. Rossman, F. H. Ives, Joe Brennemann, M. F. Chase, and W. M. Kelsey, who, in addition to being conspicuously identified with modern zinc metallurgy, are representative of the growing sentiment for coöperation and progress.

Sulpho-Cyanides in Cyanidation

By HARAI R. LAYNG

The action of these compounds in cyanide work, judging from the little discussion they have received in the technical papers, has been but slightly understood by those engaged in ore treatment. The importance of this action was not realized by myself until about three years ago, when in attempting to work out a regeneration process, now nearly perfected, I was obliged through encountering many obstacles to realize that sulpho-cyanides were of more importance than text-books and other publications had led me to believe.

Sulpho-cyanides are to be found in all cyanide solutions which have been in contact with ores containing sulphur, or compounds of that element. Cyanide has but little effect on sulphur in the cold, but when sulphur is treated with warm cyanide solutions of appreciable strength, a reaction occurs between the two which results in the formation of a sulpho-cyanide according to the following equation:

$$KCN + S = KCNS$$

Sulpho-cyanides are rarely formed during cyanidation by means of the direct action of cyanide on free sulphur, but they are readily formed through the action of cyanide on thiosulphates resulting from the action of caustic alkalis on sulphur, as is shown by the following:

$$6NaOH + 4S = Na_2S_2O_3 + Na_2S + H_2O$$
$$Na_2S_2O_3 + KCN = Na_2SO_3 + KCNS$$

Sulpho-cyanides are also formed through the action of cyanide on electro-negative or soluble sulphur, which results from the decomposition of sulphur compounds like Na_2S.

Alkaline sulphides do not react directly with cyanide to form sulphur-cyanide. They must first be broken down to soluble sulphur before their sulphur contents will react with cyanide to form sulpho-cyanides, and as solutions usually contain zinc, and possibly traces of lead, it is doubtful whether they would have a chance to break down into soluble sulphur, and then combine with the cyanide to form sulpho-cyanides, before they would combine with the metals to form insoluble sulphides. Therefore, they do not cause the formation of sulpho-cyanides in cyanide solutions to any considerable extent.

Lead acetate does not prevent the formation of sulpho-cyanides to any greater degree than that due to its combining with alkaline sulphides, before the alkaline sulphides have had a chance to break down to soluble sulphur. A number of tests which I made on Goldfield Consolidated ore show that the amount of sulpho-cyanide formed when lead acetate was added at the rate of 0.25 lb. per ton of ore, was only 2/100 lb. greater than that which was formed when one pound of acetate per ton of ore was used in otherwise parallel tests.

Lead acetate does not precipitate sulpho-cyanide from solutions which have sufficient protective alkalinity, but it precipitates the sulpho-cyanide as lead sulpho-cyanide, $Pb(CNS)_2$, from solutions which have no protective alkalinity. The following test shows the action of lead acetate on sulpho-cyanides:

Test No. 1.	KCN, lb.	Pro. alk., CaO, lb.	KCNS, lb.
A—Solution before adding acetate.....	2.38	0.44	0.984
B—Solution after adding 1½ lb. acetate per ton	2.26	0.30	0.984
Test No. 2.			
C—Solution before adding acetate.....	1.00	0.05	0.699
D—Solution after adding 1½ lb. acetate per ton	0.64	none	0.616

Sulpho-cyanides of the alkalies, when treated with acids, form hydro-sulpho-cyanic acid, according to the following equation:

$$2KCNS + H_2SO_4 = 2HCNS + K_2SO_4$$

Sulpho-cyanic acid is non-volatile in the cold, in which one respect it differs from hydrocyanic acid. It has a greater affinity for metals like silver and copper than has hydrocyanic acid. This is proved by the fact that it will replace the cyanogen contained in silver cyanide according to the following equation, which is based on the results of actual experiment:

$$AgCN + HCNS = AgCNS + HCN$$

Its affinity for silver is even greater than that of chlorine, as I have proved by tests that silver sulpho-cyanide will precipitate in preference to silver chloride from a dilute mixture of sulpho-cyanic acid and hydrochloric acid, when silver nitrate is added to such a mixture. Its affinity for gold is great, as is proved by the fact that gold is not completely precipitated from acidified solutions containing HCNS by means of reducing agents, other than those which result in the formation of nascent hydrogen even when after all of the HCN has been removed from the solution, until all of the HCNS has been precipitated from the solution.

Oxygen in the molecular form has no appreciable oxidizing effect on sulpho-cyanides, whether they exist in acid or alkaline solutions. Ozone in a dilute form, and nascent oxygen, will oxidize sulpho-cyanides to a corresponding cyanide, according to the following equation:

$$HCNS + O_3 + H_2O = HCN + H_2SO_4$$

Powerful oxidizers such as strong nitric acid, hydrogen peroxide, undiluted ozone, and others, have a tendency completely to convert the cyanogen contained in the sulpho-cyanide to ammonia. Electrolysis converts sulpho-cyanides to a yellow compound. Strong, or moderately strong acids, such as sulphuric even in a dilute state, will convert sulpho-cyanides to ammonia compounds and carbon oxysulphide, as is shown by the following equation:

$$KCNS + 2H_2SO_4 + H_2O = KHSO_4 + NH_4 + HSO_4 + COS$$

Sulpho-cyanides have but little or no solvent action

on metals like silver and copper, according to tests which I have made; but when an ore is treated with a sulpho-cyanide solution in the presence of lime, by means of air agitation, some silver extraction will be observed. Silver sulpho-cyanide is somewhat soluble in alkaline sulpho-cyanides, and it is quite possible that silver chloride in the ore would be dissolved by alkaline sulpho-cyanides according to the reaction:

$$AgCl + 2KCNS = AgCNS{\cdot}KCNS + KCl$$

In some cases I have noted that free sulpho-cyanide had no harmful effects on the extraction power of a cyanide solution. I have not noticed any reverse to this. It is quite probable that some bad effects on the extraction would be noticed in cases where solutions were loaded with free sulpho-cyanide, but this would be the effect of the inactive salts.

Judging from the evidence shown by the foregoing reactions and facts, it appears that free sulpho-cyanide is not a reducing agent in the sense as reducing agents are classified in the art of cyanidation. I have found that copper from sulphide ores invariably goes into solution as cuprous sulpho-cyanide dissolved in cyanide, as is expressed in the following final equations:

$$2CuS + 8KCN + 2H_2O = Cu_2(CNS)_2{\cdot}6KCN + 2KOH + H_2$$

$$Cu_2S + 8KCN + S + 2H_2O = Cu_2(CNS)_2{\cdot}6KCN + 2KOH + H_2$$

According to these, 1.52 lb. CNS in terms of KCNS would be formed, and 4.09 lb. KCN would be consumed per pound of copper dissolved. To prove the value of these equations, a test was made with 1 gm. of $Cu_2(CNS)_2$ and cyanide. In this the titrations with silver nitrate and potassium iodide indicator showed a consumption of 1.63 gm. of KCN. This agrees closely with the above equations, which would indicate a consumption of 1.606 gm. of KCN per gm. of $Cu_2(CNS)_2$. Further proof of the value of these equations is shown by results of tests made on sulphide ore from the Headlight mine in Trinity county, California. In this test titrations indicated a consumption of 65.16 lb. KCN per ton of ore with the solution of 13.494 lb. Cu, the formation of 21.18 lb. CNS in terms of KCNS, and 9.31 lb. $K_4Fe(CN)_6$, which is equivalent to 9.96 lb. KCN. The cyanide consumed per pound of copper, after allowing for the cyanide equivalent of the $K_4Fe(CN)_6$, was 4.1 lb. KCN, while the sulpho-cyanide was formed at the rate of 1.57 lb. KCNS per pound of copper.

These equations, representing the form in which copper exists in solutions, differ greatly from those given by Will H. Coghill in the *Press* of August 17, 1912. Mr. Coghill mentions a compound having the formula $Cu(CNS)_2$. I may mention that I have failed to find any evidence of its existence in cyanide solutions.

Silver usually enters the solutions in the form of a sulpho-cyanide dissolved in cyanide, excepting in the case of oxidized ores. The silver is usually in the form of AgCNS·KCN. It is because both silver and copper exist in many solutions as sulpho-cyanides, that a number of operators have been misled about the regeneration of cyanide due to zinc precipitation. Some of these operators have been accustomed, in conducting tests, to allow for a regeneration of cyanide in zinc precipitation from the compound of silver existing in the solution which they presumed to be $KAg(CN)_2$. The reactions upon which they based their regeneration figures may be expressed as follows:

$$KAg(CN)_2 + Zn + 2KCN + H_2O = K_2Zn(CN)_4 + Ag + H + KOH$$

$$K_2Zn(CN)_4 + 4KOH = 4KCN + Zn(OK)_2 + 2H_2O$$

According to these, 1.207 lb. of KCN would be regenerated by zinc precipitation, from each pound of silver precipitated. The regeneration of cyanide as shown by the second equation only occurs when solutions have a high protective alkalinity. My experience has been that the regeneration usually occurs when solutions have over 1 lb. CaO protective alkalinity. That the regeneration as shown above is wrong in cases of sulphide ores is clearly proved by the fact that the silver exists in solution not as $KAg(CN)_2$, but as AgCNS·KCN. The regeneration in zinc precipitation from such a compound may be expressed by the equation:

$$AgCNS{\cdot}KCN + 3KCN + Zn + H_2O = K_2Zn(CN)_4 + Ag + H + KCNS + KOH$$

$$K_2Zn(CN)_4 + 4KOH = 4KCN + Zn(OK)_2 + 2H_2O$$

Here the regeneration of cyanide in high alkaline solution would only amount to 0.603 lb. KCN per pound of silver precipitated. While in the case of low alkaline solutions a higher consumption of cyanide would take place according to the above reaction, when precipitating the solutions resulting from the treatment of sulphide ores, than would occur when precipitating solutions resulting from the treatment of oxidized ores.

I have not as yet found any evidence of the existence of a compound of zinc and sulpho-cyanide; therefore, I have presumed that zinc does not exist in solutions as a sulpho-cyanide of zinc dissolved in cyanide.

That free alkaline sulpho-cyanides are regenerated during zinc precipitation is shown by the following typical test which I made at the Belmont mill at Tonopah. In this test the solution entering the precipitation plant for 24 hours contained 2.1692 lb. free KCNS and 2.66 oz. Ag, while the solution leaving the plant during the same period contained 2.47 lb. KCNS and 0.02 oz. Ag. Here 0.3008 lb. KCNS was regenerated. Of this amount, 0.164 lb. was due to the silver precipitated, while the remainder was due to the copper precipitated. Analyses of a head solution taken from the Belmont mill at Millers shows 4.24 lb. KCNS (free) and 1.62 lb. (KCNS terms) of combined CNS. In the case of a test on Jim Butler ore, with fresh solution 1.98 lb. combined KCNS (terms) were formed. The 0.24 lb. of copper dissolved would account for 0.3648 lb. KCNS, and the 25.2 oz. Ag or 1.727 lb. Ag dissolved, would account for 1.554 lb. KCNS; making a total of 1.918 lb. KCNS, against 1.98 lb. KCNS found by titration, only a trace of which was free KCNS.

Present Conditions at Pioche, Nevada

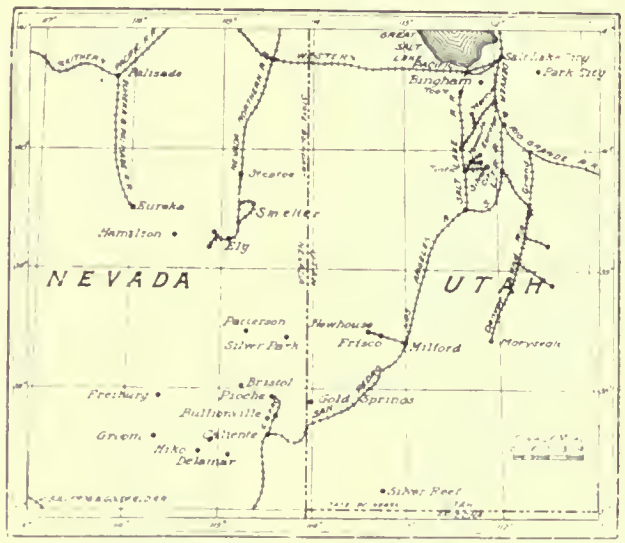
By JAMES W. ABBOTT

The leading banker of Pioche remarked today: "We are right now on the most substantial footing since we came here." This statement accurately represents the universal confidence here among the mining and business men. After passing through various phases of re-grouping and reorganization, the old Utah-Nevada and Meadow Valley properties on the hill south of town are now owned by the Amalgamated Pioche Mines & Smelters Corporation, with head offices in New York City. W. J. Palmer is president and H. R. van Wagenen is manager. The Company is operating through the old Nevada-Utah No. 1 shaft. It has revised the plant, the principal part of which is now new installation. The boiler capacity now is 500 hp. A new boiler-house has been erected and capacious coal-bins excavated. The narrow-gage railroad, up which the coal is hauled from the railroad station, has a new track above the coal-bins. There is a new double-drum steam hoist, housed in a new building. A counter-balance operates in the ladder way. There is a pump station at the 650-ft. level, and another on the 1200, which is the water line. The shaft has been sunk to the 14th level, where another pump has just been placed with a deep sump below. The water is carried through a 5-in. water column to the surface, and then runs down the main street of the town through a waste pipe. There is a new cable 2000 ft. long, a new change room with shower baths, cement floors in front of the boilers, and telephones in the mine connecting with the foreman's office.

Deep-Level Development

The Company ran a cross-cut 135 ft. long from the bottom of the shaft to the old Raymond & Ely 12th level, above which there is a considerable body of zinc ore. Another cross-cut was run from the 1400-ft. station and cut the Raymond & Ely fissure where 18 in. wide. A drift has been run to the westward on the fissure, and it is expected that that drift will cut the old Raymond & Ely Black Ledge within 600 ft. from the cross-cut. No reliable maps of those old deep workings are known to exist, and it has been necessary to make provision for the water collected in the winze which was sunk in the early days on the Black Ledge. As a protection against that water, a very long drill-hole has been carried ahead of the face of the drift, and a cement bulkhead, with heavy rail-reinforced door, placed just back of the station, with a valve, so that in case of emergency the water flow can be controlled. As the drift approaches nearer and nearer to the old winze, the flow of water somewhat increases. It has been carried down to the 1400-ft. pump station, from whence it is lifted to the 1200-ft. level and carried off through old workings. On the 12th level a narrow vein of silicious ore has been opened which sampled 1.34 oz. gold. The drift on the 1400-ft. level has opened a body of mineralized material, 7 ft. wide, some of which carries much native silver in lead and zinc sulphide. This body of ore is believed to indicate the approach to the famous old Black Ledge. Six men are working in the stope above the 1200-ft. level.

At present the Pioche Amalgamated is shipping at the rate of about 300 tons per month, but when the Black Ledge is reached and the ore-house on the surface completed, it is the intention to increase the shipments. Much of the ore now mined will not be taken to the smelters, but will be held for treatment in a mill to be erected later. The Company has given several leases.



MAP SHOWING SITUATION OF PIOCHE.

One covers the upper 600 ft. of the Raymond & Ely fissure, in ground connected with shaft No. 1. The most important of these leases is to a company of which A. Y. Smith is president, B. L. Smith, manager, and H. L. Parker, formerly of Prince Consolidated, is superintendent. This is known as the Yuba Leasing Co. The lease is to run for five years, and covers all the Company's property on the Yuba dike, and 1000 ft. of the old Meadow Valley fissure. This Company now has a 40-hp. Fairbanks-Morse hoist, with a new head-frame, at the old No. 3 Meadow Valley shaft, through which the larger part of the rich ore of the old Meadow Valley mine was hoisted. This shaft has been dismantled, but the new Company, said to have been financed in New York, is preparing to re-equip it thoroughly. It has already erected a blacksmith-shop, engine-room, and large ore-bins, and is about to install an air-compressor. It has done considerable exploratory work, all the drilling being done by hand. A long shoot of ore, running high in gold, with some silver and lead, was found on the 900-ft. level; also several shoots in the old Yuba

ELY VALLEY MINING & MILLING COMPANY.

dike workings, which were opened by a cross-cut from the 900-ft. level, 362 ft. south. A cross-cut is being run on the 6th level from the old No. 5 shaft of the Yuba dike. When the dike is struck, drifts will be run in each direction. The one to the east will in a short distance enter an old stope in Yuba workings. This leasing company has negotiated with the old Boston & Pioche for the privilege of using its workings to gain entrance to the old Yuba, known in the early Pioche days as the American Flag. This property, on the Yuba dike, has already produced millions, and the late William Lloyd, who was in charge of mining on the Yuba nearly 25 years ago, always said they left a very large amount of choice ore when the Yuba was forced to close down because the old Phoenix Reduction Co.'s smelter, down on the flat, went out of commission. In a winze from the 900-ft. level on the Yuba dike the leasing company found ore running 160 oz. in silver and ¾ oz. gold per ton. The finding of these rich bodies of ore so far from the surface, both in the old Meadow Valley and Raymond & Ely, is exceedingly encouraging.

As the result of a complicated series of negotiations, the Amalgamated Pioche Mines & Smelters Corporation now controls the old Ohio-Kentucky, which included the Greenwood. Lessees have recently shipped some high-grade gold ore from the Greenwood mine. The ore-shoot in the part of the mine from which this gold ore was taken is doubtless an extension of the old Panaca vein of the Raymond & Ely.

Several years ago the old Day mine, which, as the Jack Rabbit, in 1877 produced a vast amount of phenomenally rich ore, and the old Bristol Consolidated properties on the Bristol side of the range, were consolidated into a corporation which was known as the Day-Bristol Mining Co. The Day mine has not been worked for a long time, but the Bristol side of the range has been quite active. Mining operations on that side were conducted at great handicap because of very expensive wagon haul, averaging probably $6 or over per ton, from the mine to the Pioche-Pacific railroad at Jack Rabbit. To obviate this wagon haul, the Day-Bristol last year contracted with the F. C. Richmond Machinery Co. of Salt Lake to build an aerial tramway, to cost upward of $40,000, to be settled for with the Company's notes for $5000 per month, first payment to be made within 30 days after completion of the tramway. This tramway is now nearing completion. The properties of the Day-Bristol Consolidated have for a year or more been operated entirely by lessees. Nearly all of those worked have been entirely without equipment, and mining operations were conducted mostly by Mexican methods, but the ore is so valuable that, notwithstanding all these obstacles, it is said that all the lessees have made money.

A Little High Finance

The methods of the Day-Bristol have been so very peculiar as to suggest the doings disclosed by the former president of the New York, New Haven & Hartford railroad. The receipts were not very judiciously applied to covering the obligations of the Company, and some months ago H. E. Freudenthal was appointed receiver of the Day-Bristol Consolidated Mining Co. About three months ago the receiver filed his first report in the District Court. It showed a total indebtedness of $93,040, including cost of the tramway. Many well informed mining men regard the Bristol property as worth $1,000,000, but as there is no cash in the treasury at present, it is not easy to see how the property can be saved from disintegration. If sufficient capital were available to connect the various mines, and operate them through a single shaft at the Bristol terminus of the tramway, doubtless one of the most valuable mining properties in Nevada would be developed, but, as it is, the immediate future of the Day-Bristol is clouded with doubt. The different properties on the Bristol side, which have been operated by lessees, are the Hillside, Tempest, Iron Mine, National, Vesuvius, and Geyser.

The Mendha-Nevada, whose history goes back to the very beginning of time in the Pioche district, last year built a concentrator to treat its second-class ores. The Company has been shipping about two cars of concentrate per week. The property has recently been care-

fully examined by experts, and it is generally understood that a deal is pending.

The old Half Moon mine, about three miles on a straight line southwest from Pioche, has recently been worked on a lease by A. T. Godbe, who has shipped not only many cars of tailing, but also several cars of ore yielding more than ½ oz. gold, in addition to silver and lead. The Half Moon is a bedded vein, which was worked during the early years of this century, and the ore treated at the old Phoenix smelter. It was regarded then as a very valuable piece of property if the ore could be locally treated. A concentrator was erected on the premises and a large quantity of concentrate was made and locally treated, but the enterprise did not pay, and was abandoned, the property being acquired by the Nevada-Utah. Recently the mill building and contents, including crushers and concentrating table, were hauled away from the Half Moon to the Gold Chief property in the Chief district about 25 miles easterly. The Gold Chief ore contains principally gold. Several years ago a cyanide plant was erected at the Gold Chief mine, which was idle for a long time. It has recently been in operation, and about 500 tons of ore has been treated, with an average extraction of about $6, leaving from 80c. to $1 per ton in the tailing. The mine is now being worked and the outlook is very encouraging.

Another enterprise of promise to the Pioche district is the Alps Mining Co., organized under the laws of Oregon by a syndicate composed of Charles S. Shea and associates, of Portland. The Alps, in the closing days of Pioche's first period, was a mine of great promise. It had already produced several hundred thousand dollars under the conditions then existing. It had, in addition to the principal vein, of which the value was mostly in silver, another which produced the most beautiful free gold ever sent from that district. The old Alps owned the Floral mill, situated between the present centre of Pioche and the railroad depot. Lessees have recently shipped the tailing from this old Floral mill and have done well. The new company is going to explore for that rich free gold shoot which was finally lost in the early days.

The Pioche-Pacific railroad, 14 miles in length, from Pioche to the Day mine at Jack Rabbit, was in the hands of H. E. Freudenthal, receiver, for considerably over a year. Last October it was released from the receivership, and has managed to exist from the receipts of ore hauled from the various leases on the Day-Bristol and vicinity.

Prince Consolidated a Heavy Shipper

The most active mine in this district today, and the one at present of most promise for the future, is the group owned and operated by the Prince Consolidated Mining Co., situated about three miles southeasterly from Pioche. The ore in the upper 300 ft. consists of an argentiferous iron manganese, carrying a little lead, the orebody being a replacement in limestone. Below are found numerous beds of shale, and cutting the formation are two approximately vertical veins of ore high in silver and lead. The Company owns a standard-gage railroad about nine miles long, from the Pioche depot on the Salt Lake line to the mine, over which more than 100,000 tons of ore has already been shipped, the present production being from 200 to 300 tons of ore per day. This production can be maintained for many months without additional development. In addition to the mine, the Company owns tailing dumps at Bullionville and Dry Valley, which it is estimated are good for $400,000 when the Company is ready to dispose of them. It was from the tailing at Bullionville that the money was obtained to build the railroad. The mine is at present operated through an incline shaft to a little below the 500-ft. station, which is about water-level. The Company plans soon to exploit the sulphide zones below water level, already disclosed by diamond drills. A commodious vertical shaft, properly placed best to serve the property, is also among the plans for the future. At present the equipment consists of a 50-hp. gasoline hoist, an auxiliary 50-hp. hoist for emergencies, and a 100-hp. gasoline engine to run the air-compressor. The ore, when mined, is dropped to the 400-ft. level and from there hoisted to the surface. James Quirk, for many years foreman at the Mercur mine, is superintendent of

THE MENDHA AT HIGHLAND, EIGHT MILES NORTHWEST OF PIOCHE.

the Prince. M. C. Godbe is manager. Every attention is paid to the comfort and welfare of employees, and it is often asserted that few mine boarding houses in the United States have equalled its high standard of service. During the entire history of the operation and development of the Prince, only one fatal accident has occurred, and that was due absolutely to the victim's own carelessness. This is interesting, in view of the fact that no timbering is required in the mine.

The Virginia-Louise Mining Co., an Oregon corporation, is developing the Virginia-Louise mine which covers the extension of the Prince on the south. From the 321-ft. level a drift was driven in ore the course of the supposed strike, toward the southeast 100 ft., at which point a cross-cut was driven about 40 ft. westerly and 120 ft. easterly, where the walls were found respectively, indicating the strike of the ore-shoot to be almost at right angles to the cross-cut. This entire cross-cut from wall to wall is in ore. The main drift was then extended another 50 ft. and a second cross-cut run to the limestone on the east. The orebody was first cut in the shaft at a depth of 150 ft., with a uniform dip of about 17° to the southeast, the bottom of the drift on the 321-ft. level being a few feet above the foot-wall. Above the main bed in the shaft another bed of ore 20 ft. thick was found, with a 10-ft. bed of limestone between the two ore beds. The assay value shown by a careful sampling of this entire main bed of ore is 3% lead, 3 oz. silver, and 30% excess iron, manganese, and lime; constituting practically, at present market quotations, a $7 ore. The shaft was continued, and at the 381-ft. level another orebody was found, 18 ft. thick, with ore of a trifle higher grade. From the bottom of this deposit the shaft was sunk another 45 ft., where it entered a fissure vein with about 18 in. of silver-lead ore, averaging practically $50 per ton. That the orebodies in the Virginia-Louise are identical with those in the Prince has been demonstrated by a study of the position, thickness, and other phases of the beds. At a depth of about 250 ft. on the Prince a connection was made with the Virginia-Louise, insuring perfect ventilation for both properties, and vastly increased conditions of safety.

The Silver Park District

The pecuniary difficulties of the old Ely Valley and Horn Silver mines, which were due to the illness of George Weddell, president, have been adjusted. The Atlanta Consolidated, a company composed principally of Los Angeles capitalists, including E. M. Bray, W. T. Hook, and J. J. Giroux, owns a large group of patented claims in the old Silver Park district, 45 miles northerly from Pioche. This has been sampled by shafts, drifts, and cross-cuts to develop a sufficiently large body of low-grade free milling ore to supply a thousand-ton mill which the Company is planning to erect soon. The property is equipped with a steam hoist and necessary machinery, water system, electric light plant, blacksmith shop, store houses, assay offices, barn, boarding house, offices, and houses for a large force.

The rocks of the Silver Park district were originally sedimentaries, limestone, and sandstone, cut by an immense dike of porphyry, and later by an intrusion of rhyolite, which appears to have been the source of the mineral-bearing solutions, and in or adjacent to this intrusion orebodies were found. Much of the mineral-bearing material was a more or less complete replacement in the limerock shattered by the intrusion. The ore contains both gold and silver in commercial value, gold prevailing. In the old days, Silver Park had a daily six-horse Concord coach, connecting with the outside world at Palisade, on the Southern Pacific. It had two mills, and when the Pioche mines were producing more ore than could be handled at Bullionville and Dry Valley, a large tonnage was hauled to Silver Park, and reduced to bullion, with a treatment charge higher than the total value of the ore now produced in any of the big mines of the United States. E. M. Bray, manager, and J. J. Stubenbord, superintendent, are in charge of active exploitation now in progress.

Development of Farming near Pioche

It will be of interest to those familiar with the old Pioche as a mining camp pure and simple, to know that Pioche now seems likely to become the commercial metropolis of a very thriving agricultural area. About thirty miles from Pioche is the largest dry-farming enterprise in Nevada. W. M. Jardine, of the Agricultural College of Kansas, a recognized authority on dry farming, reported on the enterprise, and declared that he knew of no region anywhere holding out such promise for successful dry farming.

The Valley View Farming Co., a local enterprise of Pioche business men, has acquired sufficient water to mature a crop on 1000 acres by irrigation. The Association owns livestock, implements, and machinery, has a large farmhouse, barns, machinery shed, granary, etc., acquired at an expense of $25,000. About 80 cars of grain was harvested last year, with an estimated value of crop of $5000. The Company has a large tractor and plows, and hopes to have 1000 acres more broken by the autumn of 1914. Revenue for operations and equipment was obtained by monthly assessments upon each member of the Association. It is expected that the enterprise will be on a paying basis this year. Each member has taken up a half-section of land. Lake valley, in which this Association is operating, contains about 300,000 acres, nearly all open for settlement, with the choicest kind of soil. At the upper end of the valley underground waters come to the surface in the form of geysers, spouting at regular intervals, leading to the belief that artesian water can be developed, although sinking for it has not been tried.

Galvanized iron making in England is important, and exports in 1913 to Argentina, Australia, Canada, India, Japan, New Zealand, and South Afriea amounted to 762,244 tons. This material is used largely in the construction of houses.

Progress and Working Costs, Tanganyika Copper Mines

By ROBERT WILLIAMS

*In order that you may clearly understand the remarks I am about to make, particularly with regard to Benguella Railway finance, I will begin by giving some extracts from a letter I wrote November 4, 1902, to the Minister of Finance of the Congo State, at his request, to show to the late King Leopold, who at that date, just twelve years ago, adopted the general policy for Katanga development laid down in this letter. I have never been able to make this letter public before, but now certain developments have made it possible and necessary that I should do so: "In accordance with your request, I now place in writing the views I gave you when last in Brussels. The reports which have come to hand from my engineer, J. H. Farrell, now place beyond all doubt that we have discovered in the Kambove No. 2 and Likasye mines the richest copper mines in the world, both as regards magnitude and value per ton of ore. These, taken together with the other large mines we have discovered, will place your group and mine practically in control of the copper supply of the world when we have connected our mines by rail to the nearest point on the seacoast. Like the other great discoveries in Africa—namely, the Rand goldfields and the Kimberley diamond fields—this great copper mine is unique in that it is of such magnitude and in such form that, although far removed from the sea, the conditions of mining it, together with the high percentage of copper, will be so favorable that the saving in the mining alone will more than compensate for the cost of transport by rail to the sea, and the cost of smelting by imported coke, should no coal deposits be found, or should a pig-headed policy still decline to push forward the Southern Cape railway to connect our mines with the great Wankies coalfields near the Victoria falls on the Zambesi river. The profit that these mines will yield per ton of copper will therefore almost entirely depend on two factors: first, the cost of transport to the coast and to England; second, the cost of smelting the ore. Now both the cost of transport to England and the cost of smelting depends upon the building of a railway to export our copper and import our coal and other mining requisites at the nearest point on the coast to England. The nearest point is Benguella, and I am on the verge of signing a concession with the Portuguese Government to build a railway to connect our mines in Katanga with this port, subject, of course, to your approval, coöperation, and a guarantee of assistance, without which such a railway would be useless. The points we must agree upon are as follows: First, that you coöperate with us commercially, not as a state, in the actual cost of the railway" —that means it is not a political but an economic railway; "second, that you allow me to extend my line through your country to the mines; third, that you agree not to charge a greater rate on your railway section than is fixed on ours; fourth, that your import and export duties are agreed upon; fifth, that no duty is charged on machinery, coals, gold, copper, or other metals.

*This address, delivered at the annual meeting of the Tanganyika Concessions, Ltd., London, July 22, and reported in the *Financial News*, is of so much interest that we reprint it almost in full.

Comparison with the Rand

"The comparison between our discovery and, say, the Rand goldfields is that we are ready when the railway is finished to produce ore in value that would on the narrow 3-ft. average Rand bed take several millions to develop in deep-level shafts, tunnels, and extensive and costly mining plant, and the public is being invited, and, indeed, has readily subscribed to such mining propositions, being content to wait for upward of five, eight, and ten years until these can possibly produce dividends. Now, our proposition is at least open to the eye; it is above ground, so to speak, and can be inspected by all and sundry of the mining experts of the world who will take the trouble to look, and our only requirement in place of deep-level shafts, tunnels, and mining plant is our own railway, and we can get this built with an absolute certainty that such a railway will yield handsome dividends in at least as short a time as they can get down to some of the deep-level Rand mines." This letter then proceeded to show that the country could produce 1000 tons of copper per day, and gave details of probable costs with imported European coke, and further stated that by using Wankie coke and the Benguella Railway route for transport to the seacoast, copper could be landed in Europe at £24 per ton (5¼c. per pound). The letter then proceeded as follows: "It is also reasonable to expect in a sandstone formation that coal will be found not far distant from our copper, and, certainly, every endeavor will be made by us to find it by boring and otherwise; but in any case it is safe to say that the Rhodesia Railway Co. will find it imperative to connect with our Benguella railway in order to make its own system pay—indeed, the very mines in Northern Rhodesia which they had calculated on to make their line pay will be served by our railway at several pounds per ton cheaper than by their own line. By such an arrangement we will secure cheap coal and coke from Wankies, which will effect an immediate saving of at least £7 per ton of copper on 20% yield and £15 per ton on 10% yield, and the Rhodesian railway system will secure the only traffic that can make that system pay. By such an arrangement, which must come sooner or later, I shall have guided the Cape-to-Cairo railway through your

state, and thereby carried out my guarantee to the late Mr. Rhodes that I would 'see it through.' Such is the plan we should work on, and if my Portuguese railway concession was signed I would place the whole scheme before Mr. Chamberlain''—who was then Colonial Secretary—''and with his keen business insight I think I would have little difficulty in showing him: first, that our copper industry is to be one of the greatest, if not the greatest industry in Africa; second, that such an industry is bound to have a great bearing on the future politics of Africa as a whole; third, that if he works with me now in this railway business and assists me to get a connection with Wankies coalfields and the Rand he will greatly assist the commercial development of South and Central Africa as a whole, and will assist both your state and Portuguese Angoliland as well as our Empire, and thereby seal a friendship which is bound to have a lasting influence on the general welfare of all.''

Fulfillment of the Program

The entire program laid down in that letter was agreed to by the late King Leopold twelve years ago. At that date the terminus of the Cape-to-Cairo railway was many miles away from Katanga, and the Benguella railway did not exist. There is hardly one thing predicted in that letter that has not been either entirely carried out or is rapidly being carried out. I was able to negotiate and finance the extension of the Cape-to-Cairo railway to the Congo frontier through the able assistance of Jean Jadot on the Belgian side and Sir Starr Jameson on the Chartered Company's side, with the result that we have not only secured cheap Wankie coal, but discovered coal of our own at Luana, which will be useful when developed. The quantities of copper we are producing are increasing steadily, and the costs are as steadily falling, and I see no reason why, with the advent of the Benguella railway, in two or three years' time the quantities should not be largely increased and the costs either largely reduced, or, what is equally important, large quantities of low-grade ore made profitable, which can never pay without the railway. The only item in the program I laid down in 1902 which has not yet been completed, and which might have been completed some years ago if the Belgian Colonial Minister had been as energetic as the late King Leopold in these matters, is the Benguella railway. However, colonial expansion is new to the Belgians, and they have to learn, like we did ourselves, and so we have had to be patient, and I am glad to say they have now awakened to the fact that, if they are to make the minerals and railways of Katanga a success, they must have the Benguella railway, and that quickly.

M. Jadot's Recent Speech

I will deal with my finance negotiations for that line later on, and meantime will quote a few remarks from the able speech of Jean Jadot, chairman of the Union Minière du Haut Katanga, in which this Company is so largely interested, and made a few days ago in Brussels. This speech reads as follows: ''With regard to the mines, I have very little to add to the information contained in the directors' report. The two steam-shovels, with a capacity of 200 tons per 10 hours of work, which started working at the Star mine in January, are giving entire satisfaction. At the Kambove mine we shall start working in a few months' time—at the end of January, perhaps—with two steam-shovels with a capacity of from 500 to 600 tons, these being much more powerful machines than those at the Star. The results of the prospecting carried out during the last financial year and during the last few months very largely confirm, both as to quality and quantity, the early estimates, of which shareholders had been reminded in a previous communication. The data collected in proportion as our mines were developed very largely confirmed what was known on the subject of their richness. There are still only three mines working; the others will be developed in proportion with our resources in labor and with the progress of the work.

''Concerning the tin mines, we have made some experiments in working at Busanga. In order to develop them and to arrive at normal working, it is necessary for the railway to arrive near to these mines; in a few months it will be as far as these mines—that is to say, at a distance only of 60 kilometres, which is a very little matter compared with the distances dealt with when we were prospecting. It is also necessary for the labor from the north of the Bukama district to be able to arrive by railway to the mines. Therefore, prospecting has specially been carried on, and the result of these missions confirms previous estimates concerning Busanga from the point of view of richness and tonnage, which were formed as a result of the first investigations. The following will indicate the progress of our metallurgical work: Production of copper, from January 1 to June 30, 1914, 42 days' work with one furnace; 122 days' work with two furnaces; three days' work with three furnaces, which corresponds to 295 days' work with one furnace. The production for this period was 4520 tons of bars, containing on an average from 96 to 97% of copper, and 100 tons of matte containing 65%. The average production per day furnace was 15½ tons. Note—Since that date (June 30) the three furnaces have been working well and uninterruptedly.

Cost of Copper Production

''The average cost of production in 1913 of the ton of copper on truck at the works was 800 francs—that is £32 (7.18c. per lb.). The average cost for the first six months of 1914 was 778 francs (7c. per lb.). This price was found to obtain during a period when work was comparatively reduced, if it be compared with that registered since three furnaces had been working. We had anticipated an average cost of 700 francs per ton (6¼c. per lb.). This cost will certainly not be exceeded by the average cost for the financial year 1914 now in progress, because during the second six months the production will be higher than that of the first six

months and will be recorded under more economical conditions. The probable production for 1914—we say probable because we must always take into account occurrences of every kind—will be from 10,000 to 12,000 tons of copper instead of the 7000 tons in 1913. To the above-mentioned cost of production calculated on truck at the works must be added the cost of transport from Elisabethville to Antwerp, cost of handling, sale, etc., which gives as the probable cost of production at Antwerp for 1914, in round figures, about £40 per ton (9c. per lb.). Please note that this price does not include general European expenses carried to the profit and loss account, which amounted in 1913 to £18,000.

Progress at the Mines

"We are engaged in realizing a vast program of enlargement of our metallurgical works at the Lubumbashi, especially by the addition to the three existing furnaces of four new furnaces, which we hope to see working about June or July, 1915. If this hope be realized, our production for 1915 may be from 20,000 to 24,000 tons of copper. Naturally, this increase in production will have a very favorable effect upon the cost of production; the more the production increases the more the cost of production diminishes. We do not lose sight of the question of the mechanical preparation plant about which I have spoken to you previously. The question of the mechanical preparation and concentration of our ores is a very important one. We have decided upon the construction of a small experimental works built to prepare 50 tons of ore per day; further, this plant will be equipped for the investigation of different new processes which have been suggested to us for the treatment of the ores. This plant is ordered and is on the way to Africa, where it will be erected in a few months' time. The question which is of equal importanee to us is the question of fuel. We have not ceased to give it our attention. The two batteries, each of 22 coke ovens, were fired, the first in December 1913 and the second in March 1914. Their capacity for production is 3000 tons per month. They ensure the working of two water-jacket furnaces, and fulfill our expectations.

With a view to obtaining all the coke required to supply the new plant, we have entered into a very satisfactory agreement with the Wankie colliery. We have obtained a notable reduction on the transport rates for fuel on the Rhodesian railways. The question appears, therefore, to be settled on excellent terms. The year 1914, during which we shall have working coke ovens, three water-jacket furnaces, and a mechanical preparation plant, and during which we shall have commenced the construction of the new smelting plant, including four new blast-furnaces, shows signs of being one of importanee in the history of the Union Minière du Haut Katanga. We pay a tribute here to our staff, both in Africa and Europe, which has not failed to show us its devotion. In order to ensure under the best possible conditions the carrying out of our vast mining and metallurgical program, we have obtained the services of a consulting engineer, A. E. Wheeler, a man of great experience, who left a very exalted position in the copper industry in the United States in order to collaborate with us in the realization of the great work we have undertaken. Mr. Wheeler at the present time is making a thorough study on the spot of our mines and works; in fact, we can confirm what we told you in December last. The principal difficulties encountered since the beginning of our undertaking are today overcome. One, however, still remains, and one which is not the least serious, which you know has had our attention for a long time; it is the question of native labor."

M. Jadot, in finishing his speech, made the following significant statement with regard to railways: "The Benguella-Katanga railway, the construction of which is being pushed on in Angola, is to connect this territory with the mining regions of the colony, and is included in the Belgian program of the Colonial Minister. It would thus be a powerful element in the industrial development of Katanga, ensuring with the Katanga railway and the Bas-Congo Katanga railway—in complete accord with those two lines—the enormous transport which will result from the development of the great mining wealth of the southern part of the Congo."

The Future

Last year the copper output was 7000 tons. Now I am going to predict to you the future output of copper, cost of same, and profits. I believe, from all the statistics I have read, and given fair conditions of labor—and at present these look promising—that the copper output and costs of the Union Minière company will be about as follows: For 1914, 12,000 tons at £38 (7½c. per lb.) landed at home; for 1915, 25,000 tons at £30 to £32 landed at home; for 1916, 40,000 tons at about £30 (6½c.). The profits on these outputs will, of course, depend on the price of copper, but there is no indication that it will fall below present prices. Now, if copper prices are maintained, then the Union Minière company must earn something in the neighborhood of £1,800,000 to £2,000,000 sterling in profits in the next three years, of which we are entitled to about 40% after allowing for depreciation and other deductions.

I may further tell you that if the negotiations I am now carrying on are signed in their present form this Company and the Zambesia company will receive debenture interest at once from the earnings of the railway, as about £390,000 will be earned within two and a half years in carrying construction material alone, according to Pauling & Co.'s contract. If people ask you how we are financing or are likely to finance, just quote these figures to them and tell them that although our assets figure as stated in the report at £3,545,831, one of them, which is given at a cost of £392,000 in the above figure, is worth today on the market about £3,000,000 sterling, which is equal to your whole share and debenture capital.

The Taisho National Exposition at Tokyo

By WARREN D. SMITH

On my way home from the Philippines recently (June 1914), I stopped off at Tokyo for a few days, and while there called on my old friend, B. Koto, professor of geology in the Imperial University of Tokyo and dean of Japanese geologists. After we had chatted for a while about our geological experiences he proposed to take us to the big exposition which was then being held in Ueno Park nearby. We spent all that afternoon there and I went back Monday and spent the day. I was particularly interested in this exposition because it comprised in the main the exhibits which will later be sent to the Panama-Pacific, and I can say that Japan will have no reason to feel ashamed of her part in the big fair in 1915. I cannot even attempt a description of all that I saw, nor would it interest the readers of this paper sufficiently to warrant.

Plan of the Exhibition

The general arrangement of buildings is essentially like that at any big exposition, with lagoons, fountains, escalators, and casinos. The buildings, much to my disappointment, were not in the Japanese style, but this was partly redeemed by the Formosa building, which was in the Chinese style as found in that island.

Readers of this paper would naturally go first to the mining exhibits, and so did I. I was greatly impressed by the mineral production of Japan as shown by what I saw displayed in this building. The Japanese have an especial aptitude for anything requiring manual dexterity, and the wonderful display of mine models demonstrated this beyond question. The coal and copper industries were very fully represented by complete models of several of the largest plants, samples and maps, and exhibits illustrating working methods. I noticed one pile of ingots of the reddest looking copper I had ever seen. Mr. Koto told me that it was characteristic of the copper from that particular mine. Not being a copper expert, I was unable to say whether it was unusual or not. The ore is chalcopyrite.

The Petroleum Exhibit

Perhaps the exhibit which interested me most was that of petroleum and one of the first things to meet my eyes was a huge model of a California derrick with complete rotary equipment. It was about 20 ft. high. Full credit was given to California oil men for the present great success of that type of rig in Japan. What heightened the interest of everyone in this exhibit was the fact that almost simultaneously with the opening of the exposition a great gusher was struck in the north of Japan in the Prefecture of Akita, due to the use of the new (to them) type of rig. I have been told since that the production of the Echigo field (the principal one) has been doubled since the advent of the rotary. The Japanese oil men feel very grateful to Californians for what they have done to help them in this most important industry, and if I mistake not, they applied first to the *Mining and Scientific Press* for advice. I swelled, too, with pride when I saw a great spire of cubes diminishing in size from the one at the bottom (labeled 'oil production of U. S.') about two feet on a side to a wee tiny one on top about one inch on a side labeled 'all other countries.' Of course, there were some fairly respectable sized blocks in between, standing for Russia, Roumania, etc., but Uncle Sam's topped as well as bottomed them all. I believe the feeling of the Japanese oil men toward California is typical of the feeling of most of the good people of Japan. They certainly want to be friendly, and it will not be their fault if they can't be. Not once in all the places I visited in Japan, and I traveled from Nagasaki to Tokyo by rail, did I see the slightest sign of any ill-feeling toward an American. But this is getting too far away from the subject.

The Imperial Geological Survey had a small but well selected exhibit consisting of useful minerals and maps, and anyone who has ever given these maps more than a passing glance must acknowledge their excellence in point of draftsmanship, and if their geologists are anything like Mr. Koto, who, as it happens, trained most of them, they must also be very accurate.

Formosa and the Head Hunters

In another part of the ground there was one feature which served both for amusement and for educational purposes, namely, a great artificial landscape containing the ramifications of a mine with small mine cars and everything complete. The galleries were just large enough for a person of average height to walk through comfortably. From this we went across the lagoon to the Formosa building. In the centre of this large pavilion was a relief map of the island nearly a hundred feet long. All the cultural features were indicated and explained. My attention was particularly drawn to a large area on the eastern slopes of Mt. Sylvia marked off by a white line. Mr. Koto translated the label and I was able to verify what I had heard about Japan's method of dealing with the intractable hill people. The label explained that this white line marked the position of an electrically charged wire or set of wires (over 300 miles long) placed there to keep the headhunters confined. Surrounding this enclosure troops are stationed. If the people try to break through they usually come to grief, but if they come quietly begging for salt they are given a chance to come out and settle in one of the peaceful villages. You will say, many of you, how barbarous! But the Japanese believe in getting through with a painful operation quickly and they don't believe

in having to perform the operation more than once.

It is to be admitted that in Formosa, at least, they are getting results. Formosa is not as large as Luzon, is geologically very similar, and the Japanese have had control there only three years longer than we have been in the Philippines, and yet the mineral production of the former last year amounted to about $20,000,000, as against $3,000,000 for the whole Philippine group. This ought to settle for once and all those wild charges emanating from that enlightened circle of anti-Imperialists near the 'Hub of the Universe' to the effect that we Americans in the Philippines have been exploiting the poor Filipino.

Who Are the Japanese?

In that same building were many exhibits from the schools showing that the Japanese are not neglecting that side of the people's interests. There was also the Aino building, which was very interesting, particularly as the Aino is one of the parent stocks of the present composite race we call Japanese. You may not know it, but Griffis, who spent many years in the East, has said that the Japanese race is made up of Malay, Mongolian, Semitic, and Aino elements. I can account for all but the Jew. How and when he got in I don't know. There were also a Bonin islanders exhibit and a Polynesian section, all of which threw considerable light on questions which had come to mind in traveling among the less civilized groups in the Philippines.

We had dinner early in a nice hotel in a high part of Ueno Park not far from a great Pagoda. The head waitress here spoke excellent English and had lived a long time in Berkeley, California. She told me that English was now required in all the government schools in Japan.

Sayonari

As Mr. Koto and I made our way to the Shimbashi station we talked about many phases of the new Japan, and I said, "Koto, Tokyo looks very much like one of our cities. Are you going to take over the Occident entire?" "No," he said; "this is largely superficial, it won't go much deeper," and hesitating a little, but with fine courtesy, "I don't think we ought to take any more." He did not mean to be rude, and I did not so take it, for I had to admit that there was much in our Western civilization it would do no people good to adopt. I found him always ready to give praise, as for instance when we were discussing ore deposits, "You Americans now lead the world in the science of ore deposits."

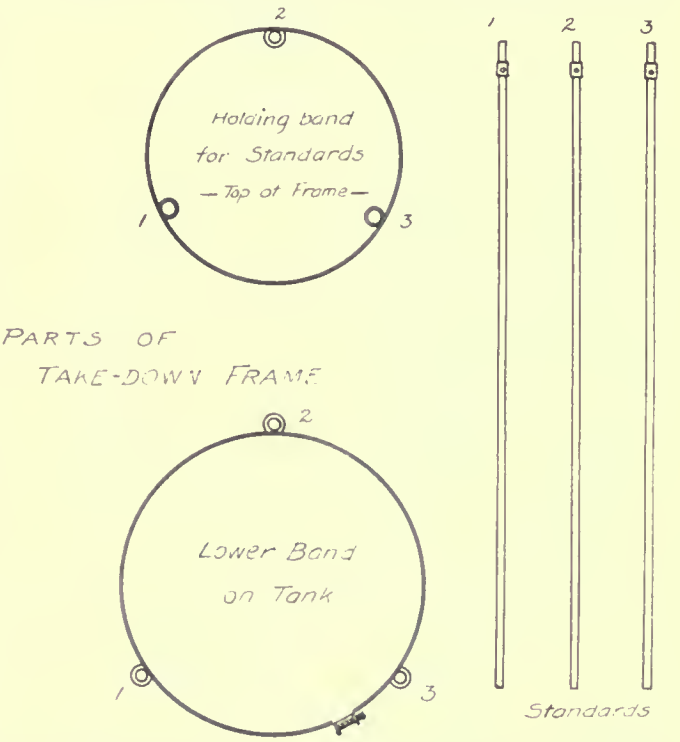
As I looked out of the train window at the fine old gray head bent forward in a bow such as only the Japanese can make, I thought "there is one of the modern Samurai of Japan," and I took away the thought that there is too much of value in Japan for us of the Occident ever to permit ourselves to become unfriendly toward them. I urge all visitors at the great fair next year not to neglect Japan's part of it, for she will be there with an exhibit well worthy of a visit and of which any nation might well be proud.

Portable Assay Outfit

By THEO. A. CLACK

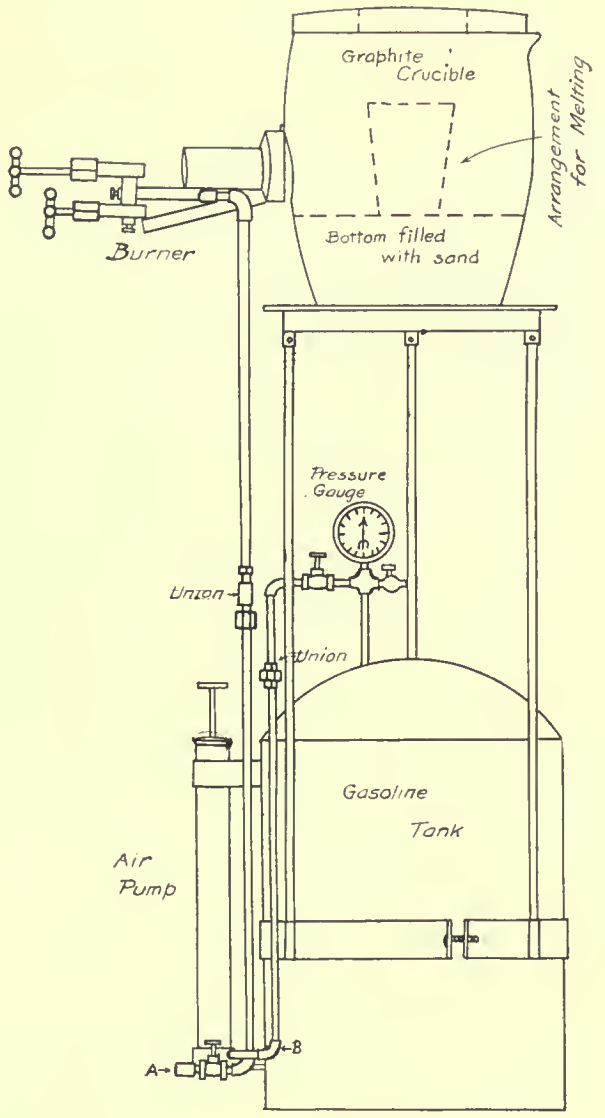
The accompanying sketch shows a portable assay outfit designed and built at the Heald's Engineering School, under my supervision in the department of mines, metallurgy, and chemistry. It is considerably lighter and cheaper than outfits sold for field work, and may with a little skill be built by most any one engaged in prospecting. It has been used in field work and has given excellent results.

The outfit consists of an 8 by 11-in. graphite crucible, 1-in. gasoline burner, pump, and tank with the necessary

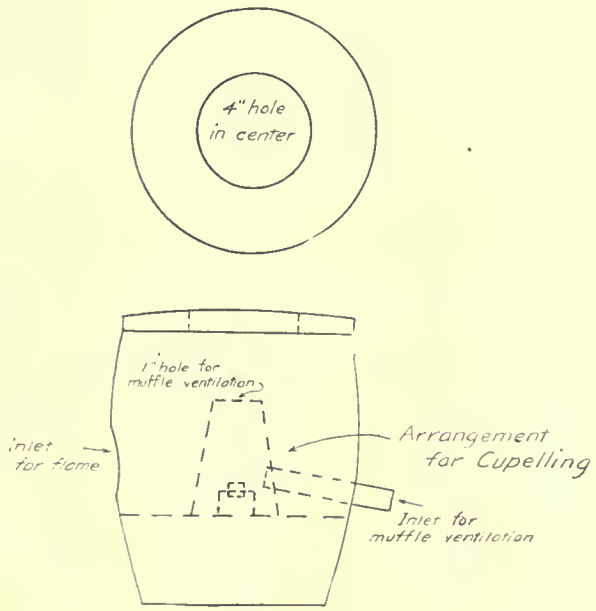


crucible support and piping. The piping, if arranged as indicated, may be taken down by unscrewing two unions. The take-down frame support for the crucible may be removed by pulling out the standards which fit into openings provided in the band about the gasoline tank and into the rest for the crucible. With this arrangement the outfit may be set up and taken down with dispatch and can be packed in a comparatively small space.

The large graphite crucible constitutes the furnace. It may be replaced easily when worn out or broken and gives sufficient heat insulation to produce a melting temperature within 15 minutes. This furnace crucible is covered with an ordinary crucible top having a 4-in. hole in the centre as indicated in the diagram. The burner is placed in front of the opening in the side of the crucible in a slanting position so that the flame may have a twirling motion within the furnace. The flame may be regulated in this way so that the hottest part of the flame envelopes the crucible or crucibles carrying the assays.



A - Gasoline Pipe
B - Air Pipe
Gasoline pipe supports Pump



CLACK PORTABLE ASSAY FURNACE.

Cupellations may be conducted in the same furnace crucible by a slightly different arrangement. There is a 1-in. hole lower than the hole admitting the flame and on the opposite side of furnace crucible which allows the entrance of a porcelain electric wire insulator. This insulator supplies air to the inverted 30-gram clay crucible shown in sketch in which the cupellation takes place. This improvision will permit good cupellation conditions. The movement of the flame around this muffle crucible creates a sort of whirlwind action above the muffle crucible, and in this way seems to aid the circulation of air within. A porcelain insulator was used above the muffle crucible which resulted in an excessive supply of air and was consequently discarded. Under those conditions feather litharge formed about the cupel until it was covered completely.

With the exercise of judgment and the acquisition of experience, satisfactory results may be obtained with a home-made outfit of this character, which is, as far as we know, considerably lighter, cheaper, and more convenient than the usual portable outfit.

Ore Contracts and the Smelter

By HERBERT LANG

Contracts for sale and delivery of ore generally run for a term of months or years or relate to a specific quantity to be delivered at the smelter yards, or sometimes at sampling plants controlled by a third party. They contain stipulations concerning the time of delivery, time and rate of payment, method and place of sampling, and the handling of the assays on which the sale is to be based. They invariably specify the percentage of the assay value to be paid, which infers the amount of deduction on each of the several metals. The contract is frequently put in the form of letters, one from the buyer to the seller offering to purchase on stated terms and in set quantities, and the reply from the seller accepting the proposal. The contract, while sufficiently rigid to be of legal value, is not very formal in tone or phrase, partly because the smelters have found that such contracts are not too stringently adhered to by the sellers. In fact, their violation is not improbable. Legal measures to compel their observance are not unheard of; but the smelters, as a rule, have not found it profitable to attempt to hold recalcitrant parties to strict account, allowing a pretty wide latitude rather than spend much money in the uncertain pastime of the law. The percentage paid varies in different localities and under different conditions. A deduction of 5% on the silver is now usually made, but I have been able in former days to buy on a 15% deduction, the recovery having averaged about 96%. A transaction like this would be held nowadays to be a robbing game, but I cannot yet see why it is not perfectly justifiable, and I wish I might do it again. By basing the treatment charge on wet weights, I made a very pretty profit. I recall that one lot of ore containing 60,000 oz. of silver yielded us $20,000 net.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Kalgoorlie Geology

The Editor:

Sir—In view of the recent voluminous discussion concerning the geology of Kalgoorlie goldfield, perhaps a few remarks, from a practical standpoint, may not be out of place.

As far as geology assists the mining engineer to find ore material carrying precious metals in quantities sufficient to pay for mining, treatment, and dividends—and to cheapen its development, it is of value, but no further, except as a scientific study. Mr. Maclaren, while on his recent visit to this field, stated that it was the physical characteristics of the country rock traversed by the lodes which chiefly determined the deposition of gold in the latter, and experience has proved the truth of this statement.

Mr. Larcombe, while dealing with felsite, a rock which has a detrimental effect on those Kalgoorlie lodes which are enclosed in it, said (*Mining and Scientific Press*, Vol. 108, p. 700) * * * "at deep levels the edges of the felsite are often 'aphanite;' the recognition of this fact has considerably reduced the thickness of the felsite."

Let us use for the time being this new term 'aphanite,' merely for the sake of reference to Mr. Larcombe's remarks. The 'aphanite' is probably, then, contemporaneous with the felsite. It is obvious that this felsite is older than the orebodies, since it is penetrated by them, so both this felsite and the 'aphanite' along its edges are older than the orebodies. The physical characteristics of felsite and this 'aphanite' of Mr. Larcombe are practically identical. Indeed Mr. Larcombe admits this: "This rock (aphanite) at deeper levels is indistinguishable from the felsite (albite porphyry)" and apparently differences are only observable under the microscope. Therefore these rocks must have had a precisely similar effect on the deposition of gold in the lodes and from the point of view of the mining engineer may be regarded as one and the same. Mr. Larcombe is then merely making confusion worse confounded by introducing a new, and as I have attempted to show, an unnecessary name into a geological situation already sufficiently complicated.

A little further on in the same paragraph, is the following: "A study of the Horse-Shoe plans shows the importance of this rock as an indicator in boring * * *" Certainly, in places there is a considerable amount, up to 30 ft., of material which is readily "separated from quartz-dolerite in cores" on either side of the Golden Horse-Shoe lodes. This is bleached and carbonated rock, resulting from the action of the lode-bearing solutions on the original quartz-dolerite, through which the lode fissure passed. The Geological Surveyors for the state of Western Australia called this 'carbonated diabase.' The term 'bleached dolerite' describes it equally well. Why then, in the name of all that is logical, do we require the name 'aphanite' for this rock, either for its schistose or its pink (through oxidations of ferrous carbonates) varieties?

J. L. Connor.

Kalgoorlie, June 22, 1914.

[A more detailed account of the district in question, prepared by Mr. Larcombe for the *Press*, will be printed later.—Editor.]

Valuation of Dredging Ground

The Editor:

Sir—To elaborate on the article by L. A. Decoto in the *Mining and Scientific Press* of May 9, 1914, I submit a mathematical demonstration of the principles involved in estimating the value of ground and then show their applications to the theoretical example given by him.

The following nomenclature will be used. The product of yard value by depth in feet will be called 'valence' and designated by the letter v. The depth of the prospect hole in feet will be designated by d.

Starting with the simplest geometrical figure, a triangle, A, B, C, Fig. 1, at the corners of which drill holes

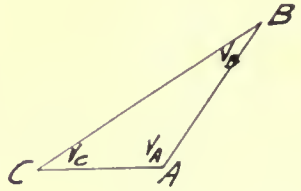


Fig. 1.

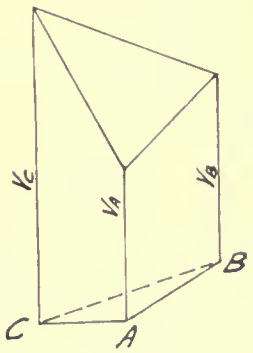

Fig. 2.

have been sunk, giving the valences v_a, v_b, v_c. The valence of the entire triangle can be shown graphically by the volume of a prism, the base of which is equal to the triangle A, B, C, while the vertical sides may be represented by some convenient scale equal to the corresponding valences. This has been done in Fig. 2.

It is assumed in this figure that $v_c > v_b > v_a$, and that the area of the triangle A, B, C is unity, also that the valences increase uniformly along the lines AC, AB, and BC. While this last assumption is not borne out by actual experience, it is a safe one to make, provided the differences in yard values are not excessive and that the distance between individual prospect holes is not a great one.

The volume of the prism $= \frac{v_a + v_b + v_c}{3} \times$ area of triangle A, B, C, and as this area has been assumed as unity: $\frac{v_a + v_b + v_c}{3}$. That is, the average valence for a triangular piece of ground is the arithmetical mean of the valences at its corners.

Similarly we get for the cubic contents of the prism, as existing on the ground, for a triangle of area of unity: $\frac{d_a + d_b + d_c}{3}$ and for the mean yard value, $\frac{\frac{v_a + v_b + v_c}{3}}{\frac{d_a + d_b + d_c}{3}}$ or $\frac{v_a + v_b + v_c}{d_a + d_b + d_c}$.

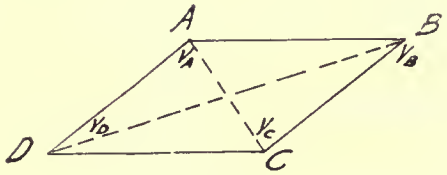

FIG. 3.

Taking now the case of a parallelogram, Fig. 3, we can divide it into two triangles by either one of the diagonals AC or BD. Using AC first, we have for the triangles ABC and ADC the following expressions for their average valences: For ABC, $\frac{v_a + v_b + v_c}{3}$, for ACD $\frac{v_a + v_c + v_d}{3}$, and for the parallelogram, as the two triangles are equal, the arithmetical mean of the above expressions, or $\frac{2(v_a + v_c) + v_b + v_d}{6}$.

Similarly we get for the same parallelogram, using triangles ABD and BCD the following expression: $\frac{2(v_b + v_d) + v_a + v_c}{6}$.

For the equality of these two expressions, we have after reduction, $v_a + v_c = v_b + v_d$. That is, the sum of the valences at opposite corners of the parallelogram must be equal.

Constructing the valence prism, as shown in Fig. 4, it can readily be seen that the condition of equality of the sums of the valences at opposite corners means geometrically, that the prism shall be terminated by a plane surface. The condition just stated is hardly ever fulfilled in practice, and to obtain the most probable value for the valence of the prism, the arithmetical mean between the two different expressions derived above will have to be taken, as follows:

$$\frac{2(v_a + v_c) + v_b + v_d}{12} + \frac{2(v_b + v_d) + v_a + v_c}{12} = \frac{v_a + v_b + v_c + v_d}{4}.$$

That is, the most probable average valence of a piece of ground, having the shape of a parallelogram is the arithmetical mean of the valences at its corners.

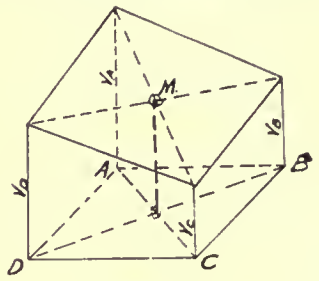

FIG. 4.

Analogous to previous derivations, we get for the mean yard value $\frac{v_a + v_b + v_c + v_d}{d_a + d_b + d_c + d_d}$. As the prospecting of dredging ground can generally be reduced to the described simple geometrical figures, no other shapes need be considered. Narrow deposits following the sinuosities of a stream do not lend themselves to this method of prospecting and are not considered in this article.

To test this method on the theoretical example, shown by L. A. Decoto, and compare the results from it with those obtained by him, I have divided the field into tri-

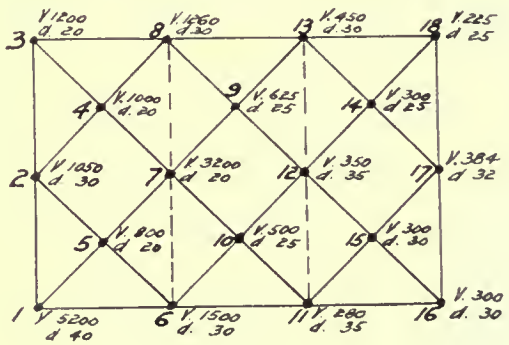

FIG. 5.

angles and squares, as shown in Fig. 5. In calculating the average yard value, it is of course unnecessary to take each figure by itself, it is only necessary to ascertain by inspection into how many triangles and squares each valence and depth enters, for instance, No. 2 would enter into three, No. 7 into four, etc.

We can thus write down for the sum of the valences:

$$2\left\{\begin{matrix}5200\\1200\\225\\300\end{matrix}\right\} + 3\left\{\begin{matrix}1050\\1260\\450\\384\\280\\1500\end{matrix}\right\} + 4\left\{\begin{matrix}800\\100\\3200\\500\\625\\350\\300\\200\end{matrix}\right\} = \begin{matrix}13850\\14772\\28300\\56922\end{matrix}$$

$6925 \qquad 4924 \qquad 7075$

For the sum of the depths, we have:

$$2\left\{\begin{matrix}40\\20\\25\\30\end{matrix}\right\} - 3\left\{\begin{matrix}30\\30\\30\\32\\55\\30\end{matrix}\right\} + 4\left\{\begin{matrix}20\\20\\20\\25\\25\\35\\25\\30\end{matrix}\right\} = \begin{matrix}230\\561\\800\\\hline 1591\end{matrix}$$

$2 \times 115 = 230$; $3 \times 187 = 561$; $4 \times 200 = 800$

And for the average yard value of the tract, we have:

$\frac{56922}{1591} = 35.8$ cents.

To show how the calculation of the yard value of small tracts compares with that of larger ones, I have subdivided the tract shown by the dotted lines, running from hole No. 6 to No. 8 and from hole No. 11 to No. 13, and have calculated each of the three tracts separately. Only one of the calculations will be shown in detail, the one for tract comprised between holes 1, 3, 8, and 6.

Sum of valenees:

$$2\left\{\begin{matrix}5200\\1200\\1260\\1500\end{matrix}\right\} - 3\left\{\begin{matrix}1050\\3200\end{matrix}\right\} + 4\left\{\begin{matrix}1000\\800\end{matrix}\right\} = \begin{matrix}18320\\12750\\7200\\\hline 38270\end{matrix}$$

$2 \times 9160 = 18320$; $3 \times 4250 = 12750$; $4 \times 1800 = 7200$

The sum of the depths:

$$2\left\{\begin{matrix}40\\20\\30\\30\end{matrix}\right\} - 3\left\{\begin{matrix}30\\20\end{matrix}\right\} + 4\left\{\begin{matrix}20\\20\end{matrix}\right\} = \begin{matrix}240\\150\\160\\\hline 550\end{matrix}$$

$2 \times 120 = 240$; $3 \times 50 = 150$; $4 \times 40 = 160$

The average yard value: $\frac{38270}{550} = 69.6$ cents.

By a similar calculation, we obtain for tract 6, 8, 13, and 11: Average yard value $\frac{22130}{615} = 36.0$ cents.

And for tract 11, 13, 18, and 16: Average yard value $\frac{7112}{661} = 10.8$ cents.

Combining the three tracts, we have for sum of the valences: $38270 + 22130 + 7112 = 67512$, and for the sum of depths: $550 + 615 + 661 = 1826$.

And for the yard value of the whole tract:

$$\frac{67512}{1826} = 37.0 \text{ cents.}$$

It will be noticed that this amount is larger than the one obtained by considering the entire tract. The reason for the discrepancy lies in the fact that the yard values do not increase and decrease uniformly in all directions between the individual test holes. To show this it will only be necessary to take one of the squares of Fig. 5, for instance, the one formed by the holes 7, 9, 12, and 10 and find the valence at its centre. Figuring from holes 7 and 12, it would be the average between 3200 and 350 or 1785; figuring from holes 9 and 10, it would be 562, or only about one-third of the other value. This shows that the determination of the value of a small area from a few drill holes is very problematical.

Referring to Fig. 5, it can be seen that the area may be divided into triangles in two different ways, one being by vertical division lines, the other by horizontal. To check up the results obtained for the average yard value of the tract, the calculations were made for both subdivisions, resulting in each case in a value of 35.7c., which practically coincides with the result obtained by the method of division into squares and triangles, which latter saves a great deal of time and labor in the calculation. The rectangle between holes 1, 3, 8, and 6 was also figured by dividing it into triangles by vertical and horizontal lines, the former giving a yard value of 67.9c., the latter of 70.8c. The higher value obtained in the second case is due to hole No. 7, which in that calculation enters four times, while in the first case it occurs only three times.

It will be noticed that the yard value for the tract, as derived by the method here outlined, differs a little from the one shown by Mr. Decoto, being about 5% smaller, which is on the safe side. From the yard value thus obtained should be deducted a certain percentage to obtain the actual recovery, and, while I have data on this subject, they are not exhaustive enough, nor do they cover a sufficient range of different installations, to warrant any but the most general conclusions, which may be stated as follows: The higher the prospect value, the greater should be the percentage of loss in recovery, starting with about 5% on 5c. per yard, and extending to perhaps as high as 50% on 75c. per yard; it being understood that these prospect values are for large areas and a great number of prospect holes. When it comes to small areas, covered only by two or three holes, a rough guess, tempered by good or poor judgment is all that can be offered. It is to be understood that the judgment is good when the results show in your favor and vice versa. The trouble is that it is impossible to be sure of your judgment beforehand.

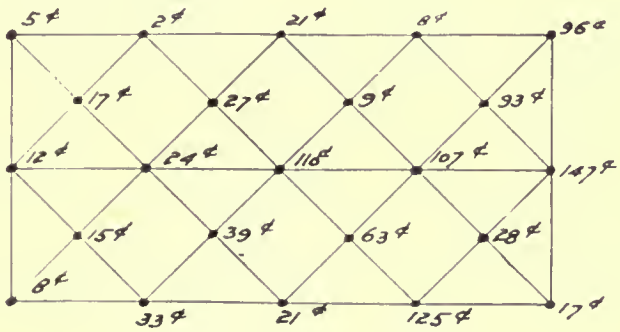

FIG. 6.

It may be imagined by those not familiar with dredging prospects that the theoretical example shown by Mr. Decoto represents unusual conditions. To set at rest any doubts on this score, I have shown in Fig. 6 the results obtained in prospecting part of a large piece of ground, which will illustrate the practical value of Mr. Decoto's theoretical example.

L. J. HOHL.

San Francisco, August 1.

[The importance of this subject warrants further discussion. What have you to say?—EDITOR.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COMMERCIAL MANGANESE ores at present in America are those which contain at least 35% of manganese.

RAINFALL in some mining countries is very heavy. At the Ashanti mine, West Africa, the fall was 21.54 in. in 27 days of July; while 4.82 in. fell in 4.5 hours on June 23, resulting in part flooding of the mine. The temperature ranged from 67 to 68° Fahrenheit.

STAMP BATTERY SHOES, when worn to from one to two inches in thickness, may be used as dies. A cast-iron false die is used for this purpose. This is fitted with a recess into which the shank of the inverted shoe fits snugly.

COMPENSATING WEIGHTS, to allow for the loss of crushing power resulting from wear of stamp shoes, are sometimes used. These consist of halved cast-iron collars which are clamped on the stem just above the head. An alternative method of maintaining output, which involves considerable labor, is to transfer shoes when worn down, to a battery having heavier heads.

CYANIDE BULLION may be brittle from a variety of causes. Lead is the most common cause of brittle bullion. It may get into the bar if an excess of lead salts is used to facilitate precipitation; it may be that the zinc contains a little lead. Of course sulphuric acid treatment does not remove it from the precipitate. Bullion containing over 10% zinc is likely to be brittle, especially if there is but little silver present.

ORDINARY METHODS OF COMMUNICATION are not sufficient for the great mining enterprises of today. At the Homestake properties, in South Dakota, a complete telephone system is maintained, reaching into the mine, and to all surface plants at Lead, to the timber camps, pumping stations, electric-generating stations, etc. The telegraph is also used, and the latest equipment for communication to be installed is a wireless telegraph.

LARGE ITEMS OF WASTE will be found, by close inspection, to exist at nearly all mines, no matter how small the scope of operations, if there is no adequate check on supplies issued to the employees. A warehouse, or storeroom, where various fittings are kept, and issued only on requisition, will, properly handled, effect remarkable economies. At a certain mine the consumption of screens on the stamp batteries was almost halved by an energetic manager. This same mine's consumption of giant powder was almost cut in two. The same ratio holds good with nearly all of his other supplies, such as pipe fittings, bolts, nuts, screws, crucibles, candles, blacksmith coal, and dozens of other items.

TEMPERATURES in a beehive coke oven charge during a 44-hour burn are as follows, according to T. B. Williams, of Canmore, Alberta, Canada: fresh charge put in oven, 1260°F.; period of ignition, two hours later, 1330°; air admitted above charge, four hours later, 1870°; some draft shut off, eight hours later, owing to too violent ignition, 1760°; volatile hydrocarbons being driven off, and part burned above the charge, from 1830 to 1540°; oven door luted up and oven tranquil, 1470 to 1260°; and owing to the drop in temperature, a little air was admitted and a small amount of the fixed carbon was burned off, after which the cover was placed on and the door luted up tight, 1980 to 1800 degrees.

ANALYSIS of the strong circulating solution at the Meyer & Charlton mine, on the Rand, is as follows, according to H. E. Williams, in the *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa:

	Per cent.	Parts per 100,000.
Sodium cyanide	0.03880	38.80
Sodium ferrocyanide	0.00570	5.70
Sodium zinc cyanide	0.04080	40.80
Sodium cuprocyanide	0.00660	6.60
Sodium nickel cyanide	0.00419	4.19
Sodium aurous cyanide	0.00091	0.91
Sodium cobalticyanide	0.00290	2.90
Sodium cyanate	0.00780	7.80
Sodium thiocyanate	0.01458	14.58
Sodium sulphate	0.16630	166.30
Sodium chloride	0.04614	46.14
Calcium sulphate	0.06600	66.00
Calcium hydroxide	0.02440	24.40
Free ammonia	0.00136	1.36
Total	0.42648	426.48

The total cyanogen expressed as sodium cyanide is small, notwithstanding that the liquor is one of the strongest on the Rand. The double zinc cyanide formed must for the greater part be brought into play as a solvent for gold, the zinc being removed from solution and alkaline cyanide liberated by some reaction, or reactions, that take place during the operation of gold extraction, and there are many such possible reactions, otherwise one cannot account for the comparatively low amount of this compound which is present in the liquor. Again, the total free cyanide returned by the usual Liebig test, in the presence of so many other double cyanides, is much too high as an expression of the actual free cyanide present, even when potassium iodide indicator is used.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

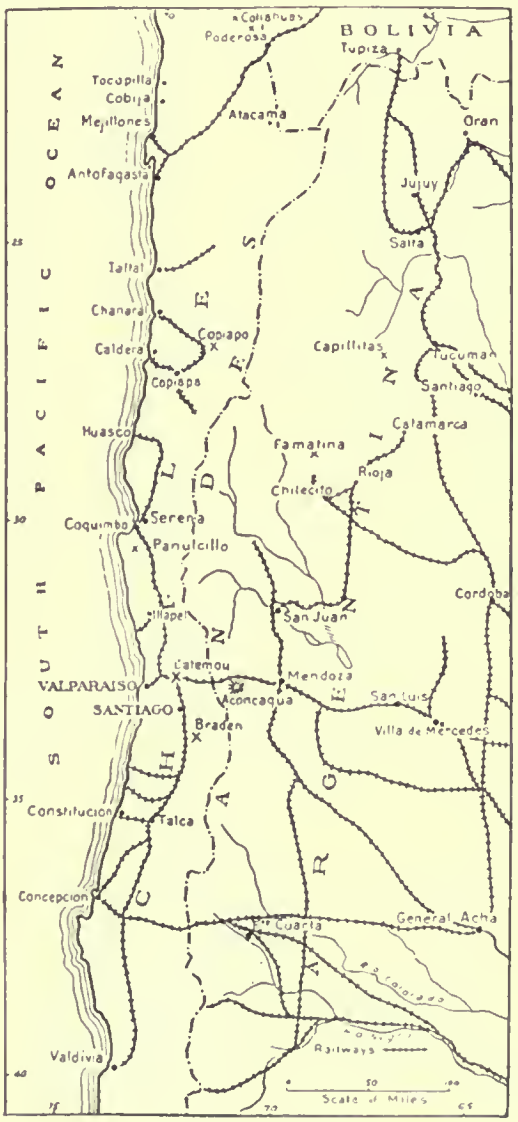
ALLEGED DISCOVERY OF LARGE GOLDFIELD IN ALASKA ABSOLUTELY UNTRUE.—NIPISSING OPTIONS AT POACUPINE.—A. S. & R. CO.'S REPOAT.—WORK AT CHUQUICAMATA AND BRADEN.

New York had its first really thrilling mining news in a long while last week when the daily papers published an account of an interview supposedly given out in Tacoma by Stephen Birch, who is president of the Beatson Copper Co., vice-president and manager of the Kennecott Mines Co., Alaska Development & Mineral Co., and a director of the Copper River & Northwestern railroad and the Alaska Steamship Co. In the alleged interview Mr. Birch was made to say that in the Broad Pass district, which is southwest of Fairbanks and northeast of Mt. McKinley, there is a newly discovered gold-bearing district surpassing even the Transvaal. The gold-bearing veins, at the northwest, were from 200 up to 2000 ft. in width. A 100-ft. vein averaged $15 per ton across the whole width, and a 14-ft. 'pay-streak' on the hanging wall side averaged $250 per ton. The poorest of these wonderful veins was supposed completely to eclipse the Alaska Treadwell and Juneau. Reporters scurried off to find Daniel Guggenheim, and persuaded him to say that if Mr. Birch said such things they must be so, which was promptly rendered in the papers as a statement that Mr. Guggenheim had a telegram from Mr. Birch confirming the wonderful discoveries, and that Mr. Birch was bringing sackfuls of the ore to New York with him. A few days later Mr. Birch arrived in person and explained that he had not been in Tacoma, nor had he visited the Broad Pass region, concerning which he had no information. He had actually been on the east slope of the Wrangell mountains, and had there seen some quartz veins that were of promise as prospects. On this slender basis, probably from an overheard conversation, the wild story was set afloat.

Morton Webber, with a corps of assistants, is now engaged in valuing the McIntire mine for the Nipissing Mines Co., which has an option on shares, and if the ore reserves prove equal to the vendor's representations, the option will be promptly exercised. The Nipissing has also taken an option on the Teck-Hughes. This is the first venture of the Nipissing into the Porcupine district, and it is interesting that its attention is directed toward promising properties instead of mere prospects. The Nipissing has been doing well lately. The war has not affected operations, as the mine has enough cyanide on hand to last until the middle of February.

The report of the American Smelting & Refining Co. for the six months ended June 30 showed a surplus of $1,956,691 available for dividends, as compared to $2,017,894 in the same period last year, corresponding to 3.91% and 4.03% respectively. In his accompanying statement, the president, Daniel Guggenheim, draws attention to the good showing made during a period of disturbance in Mexico, and adds: "the income account for the period shows surplus earnings over both preferred and common stock dividends to be $956,691." Details of the report will be given in another issue.

The disturbance incident to the war has not had any marked effect on construction and development work at Chuquicamata, Chile, and it is hoped that it will be possible to start the first unit of the leaching plant some time during next March. The electrical equipment for the power-house, transmission line, and electrolytic plant had been contracted for in Germany, but fortunately it had nearly all been shipped, and was either in Tocopilla or on board Chilean steamers when the war broke out. As the German ports are not yet blockaded, it is possible that even the small amount not yet shipped can be forwarded, and if not the American plants affiliated with the German company will undertake delivery. The difficulty with the management of the Antofagasta-Bolivia Railway Co. over water-supply has been practically settled,



MAP OF CHILE.

and was indeed never so serious as it appeared. Even if the Chile Copper Co. had been unable to secure the gravity supply from the Loa river, it could have secured a sufficient supply by pumping from a point within its own property lines. And there is a third source of water-supply also available, but at a considerable distance. The pipe for the water-supply line has been delivered, and is now being laid. Operations at the Braden have been much interfered with by the unusually hard winter which has been experienced there, but the

output for August, which is at the end of the winter in Chile, was 4,532,000 lb., the largest month in the history of the Company. This was largely due, though, to cleaning-up around the smelter. The output for the first eight months of this year has amounted to 18,315,000 lb., as compared with 11,056,000 lb. last year for the same period. The mill recovery during August averaged 72.7%. Shipments of blister copper have been diverted from Europe to New York. Nothing has been done recently in regard to the proposed leaching plant at Braden.

WASHINGTON

No Mining Legislation Probable This Session.—Conservation Bills.—Alaska Coal Land Leasing Bill.

Though there are a considerable number of bills in Congress bearing specifically on mining, it is generally conceded that they have no chance of enactment in what remains of this session. Some hoped for bills are thus deferred and some not desired are postponed and probably prevented from becoming law. M. D. Foster, of Illinois, chairman of the House committee on mining recently, said: "I see no chance for further mining legislation during this session of Congress, not even for the commission to codify the mining laws and the mine-rescue legislation. Most of the mining bills carry appropriations, and the leaders in Congress are set against granting any more appropriations for anything. It has to be tremendously necessary to get it by. No such pressure exists in mining legislation, however much desired. I am quite sure we will be able to get action in Congress on our more desired projects in the short winter session. There will then be no such pressure in the treasury, and after elections Congress is always more liberal toward legislation carrying money. It is only a matter of waiting a few months—six months. That we can do." However, the conservation bills are making their way through the House and they affect mining. They have not yet got through the House, and there seems no likelihood that the Senate will undertake to consider them at this session. An attempt was made last week to get the Senate to consider the bill granting the leasing of coal lands in Alaska. The bill has passed the House and came from the committee of public lands of the Senate with a report on it by Key Pittman of Nevada. He surprised the Senate by asking the body to consider the bill immediately. Mr. Shafroth of Colorado at once opposed this, saying: "I have very serious objection to a leasing system. I think it is wrong. I do not think it is expedient and I do not think it is practicable. This is a great measure and it seems to me that a proposition to put it through by unanimous consent cannot be seriously made." The Senate bill referred to requires that after the execution of surveys the President shall designate and reserve from use, location, sale, and lease 5120 acres of coal-bearing land in the Bering coalfields and 7680 acres in Matanuska coalfields to be mined under the direction of the President when it becomes necessary by reason of an insufficient supply of coal at a reasonable price for the requirements of government works, construction and operation of government railroads, for the Navy, for national protection, or for relief from oppressive conditions. The unreserved coal lands shall be divided by the Secretary of the Interior into leasing blocks or tracts of 40 acres each, or multiples thereof, in no case exceeding, however, 2560 acres, the leases to be awarded through advertising and competitive bidding to United States citizens or associations. There may be a consolidation of leases and holdings, but not beyond 2560 acres. It is a felony to get more in any manner. For the privilege of mining and extracting and disposing of the coal the lessee shall pay to the United States such royalties as may be specified in the lease, to be, however, not less than 2c. nor more than 5c. per ton, payable one month after the shipment of the coal from the mine. An annual rental is also required to be paid of 25c. per acre for the first year, 50c. for the next four years, and $1 per acre for every year thereafter so long as the lease runs. The leases are to be for not more than 50 years. To provide for strictly local and domestic needs, arrangements are permitted in the bill by which the Secretary of the Interior may issue limited licenses granting the right to prospect for, mine, and dispose of coals on specified tracts not to exceed ten acres and without payment of royalty for the coal mined. [Telegraphic advices state that the coal, petroleum, phosphate leasing bill passed the House Wednesday last.]

KALGOORLIE, WESTERN AUSTRALIA

Good Developments in the Golden Horse-Shoe Mine at 2900 Feet.—Calc-Schist Not Stopping Deep Prospecting.—Chaffers, Bullfinch, and Sons of Gwalia Mines.

In a cross-cut on the 2900-ft. level, in the middle of May, the Golden Horse-Shoe company cut No. 4 lode, 100 ft. east of the shaft, where it assays $18.36 per ton over a width of 15 ft. and carries visible gold and telluride. This is a very important development, because this lode was only 15 ft. from the Great Boulder boundary at 2630 ft., 39 ft. at 2780 ft., and is now 95 ft. at 2900 ft. At 2630 ft., the lode where cut assayed $25.42 per ton over a width of 7 ft., and at 2780 ft. $14.28 per ton over 16 ft., so that it has maintained its width and value to the lowest point yet reached. On all three levels the lode has also been proved to carry telluride and visible gold in places. Apart from these rich developments in the deepest levels, the Company has opened a practically new mine at the south end of its 24-acre property. Down to No. 12 level the ore-shoots in No. 2 and 3 lodes, which have provided the bulk of the mill supplies, since No. 4 lode originally passed into the Great Boulder ground at 950 ft., cut out before reaching 500 ft. south of the main shaft. On No. 13 level the shoot in No. 3 lode was worth from $6 to $8.64 to 800 ft. south of the main shaft, or 70 ft. south of No. 2 shaft. On No. 14 level the shoot was longer and assays from $7.68 to $28.56 per ton up to the Chaffers boundary on the south, a distance of 1100 ft. south of the main shaft. Similar results have been met with at both No. 15 and 16 levels, and the shoot in No. 3 lode has already been proved to extend as far south as No. 2 shaft at No. 17, 18, and 19 (2000 ft.) levels. The shoot in No. 2 lode has not been driven on to the same extent, but still it has been proved to continue in highly profitable ore as far south as No. 2 shaft, from the thirteenth to the sixteenth levels, whereas at No. 10, 11, and 12 it was very poor after passing 500 ft. south of the shaft. Several winzes between levels are now being driven to open this ore.

There appears to be some chance of its being proved that Malcolm Maclaren and other geologists were as premature in predicting the early demise of the Kalgoorlie-Boulder mines, because of the intrusion of calc-schists, as geologists were in the Kolar field of India a dozen years ago, because of an intrusion of a barren zone. In spite of Mr. Maclaren's pessimism, the managements of the Lake View Consols, South Kalgurli, and Oroya Links are continuing deeper development and report satisfactory results, and even the Kalgurli company is not quite satisfied that profitable ore will not be found in deeper ground, and continues prospecting by diamond-drilling.

Erection of the new plant on the Chaffers at Kalgoorlie is making slow progress and seems unlikely to be in operation much before the end of the year. The stack is the largest in the district, being 7 ft. 9 in. diameter. Sinking winzes to connect No. 15, 16, and 17 levels is making good progress, and the shaft has been re-skidded from the surface in preparation for the starting of the mill. The working capital called up since last July of $231,000 has been nearly all

spent, and the future success of the Company will have to depend chiefly on the revenue from the mill. The management has not followed John Morgan's (former manager of the South Kalgurli and who reported on the Chaffers) advice given in May, 1912, to sink deeper for the rich ore being opened in the Horse-Shoe. The deepest level in Chaffers is 2261 feet.

On December 31, 1912, ore reserves of the Bullfinch mine at Southern Cross, above 210 ft. were given as 177,300 short tons assaying $13.10 per ton, of which 117,300 tons was in No. 3 northern series. Although only 29,900 tons was treated from here during 1913, the ore reserves at the end of 1913 included no ore in No. 3 northern series above 210 ft., and only 24,700 tons above 310 ft. This shows that the result of the creep or collapse of ground was the loss of 87,400 tons above 210 ft., and a curtailment of development at 310 ft. In fact, very little development has been done on No. 3 series since the creep, and during the last half-year monthly progress reports do not refer to it. Shaft-sinking has been entirely suspended for the last 18 months, and this may be accounted for by the fact that, in 1912, a diamond-drill hole from No. 3 level cut granite at a depth of 400 ft. at a distance of 700 ft. east of the main shaft.

Prospects of the Sons of Gwalia mine at Leonora appear to be improving at depth. The lode at No. 17 and 18 levels was poor, owing to the intrusion of epidiorite, but, at No. 19, the shoot for a length of 1100 ft. contained ore assaying $8.40 for the full width of the drift. A winze below this level, sunk 149 ft. to the horizon of No. 20 level, was in ore assaying $14.88 per ton over a width of 62 in. At the bottom of this winze a drift put in 100 ft. assays $22.26 per ton over 116 in. A prospecting shaft is being sunk in the northern section of the property to try and pick up an ore-shoot beyond the epidiorite intrusion.

Gold production of the state in June was $2,145,400, with $476,000 in dividends. Yields of the principal mines were approximately the usual average given in former issues of this journal.

TORONTO, ONTARIO

Conditions at Cobalt.—Dome Gold Yield.—Iron and Steel Companies' Position.—Consolidated Mining & Smelting Co.'s Dividend.

The short-lived period of depression in the Cobalt silver industry, following the outbreak of the war, has passed away, and the output is again normal, shipments going forward freely to the smelters. On September 8 the Kerr Lake, after a three weeks' suspension, resumed with a full staff. The Drummond Fraction is resuming with 25 men. Shareholders of the Bailey mine are being asked to oppose the sale of the property for debt. It is stated that a deliberate attempt is being made to wipe out the stockholders' interests, and a protective committee has been formed to fight the sale.

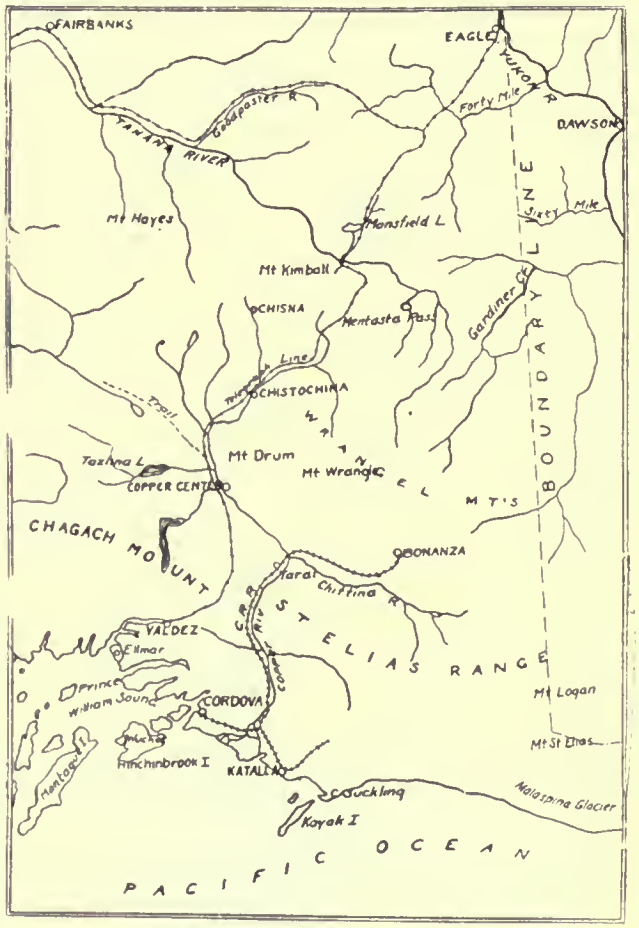
The output of the Dome for August was the largest since January, amounting to $90,893. The amount of ore treated, 20,170 tons, exceeded that of any previous month, and the average value was $4.50 per ton.

Whatever may be the outcome of the movement to induce the iron and steel manufacturers to pursue a policy of expansion, with a view of capturing a portion of the German export trade, the present condition of depression is reflected in the passing of the dividends on deferred and common stocks by the Nova Scotia Steel & Coal Co. The president, R. E. Harris, in a circular to shareholders, states that this action has been taken in view of trade depression which has been emphasized by the European war. It certainly will not tend to restore confidence, especially if, as is considered likely, it foreshadows a similar course on the part of the Dominion Steel Corporation, which is in a distinctly less favorable position than the Nova Scotia.

CORDOVA, ALASKA

Changes at the Bonanza.—Jumbo Developing Favorably.—Mother Lode, Great Northern, and Other Copper Mines, —Nabesna, Nazina, and Chisana Placers.

The capacity of the mill at the famous Bonanza mine, owned by the Alaska Syndicate, has been increased within the past few weeks from 300 tons to 500 tons per day. The development work is going forward and is now down to a 700-ft. level with an incline something over 1300 ft. long, still in a splendid body of ore. As is well known, great quantities of high-grade glance are found in this property, ranging from 60 to 72% copper. The development work is still opening up large bodies and the ore is brought to the mill over an aerial tram three miles long. Another aerial tram is being erected



MAP OF CORDOVA DISTRICT.

from the millsite to the Jumbo property which belongs to the same people. This tram will be 3½ miles long and will be completed before winter. The Jumbo lies on the same contact as the Bonanza and promises to be even a better producer than the Bonanza. They are now down below the 400-ft. level and the ore taken out has paid for all development up to date, notwithstanding that it has been hauled to the mill by team.

The Mother Lode copper mine, lying twenty miles distant by trail and on the opposite side of the mountain from the Bonanza, is owned by New York people, of whom James J. Godfrey is president. Last winter this Company shipped 500 tons of high-grade ore to the Tacoma smelter, hauling it over snow and ice. Development work has gone steadily ahead and the property is said to be looking well, but no ore is shipped because of the lack of transportation.

Work on the Alaska United Copper & Exploration Co.'s group of claims at the head of Dan creek, known as the West-

over group, is being pushed by the superintendent, Mr. Foster. They have a vein of solid bornite ore 8 ft. wide with a depth of 400 ft. All this property needs is a railroad connection to put it in the shipping class. This is also true of a group of claims owned by the same company at the head of the Kuskalina, and known as the Finch group. The Tjosevich property, directly across the Kennecott glacier from the Bonanza mine, is being examined by representatives of the Granby company, and nothing but assessment work has been done on this property this year. This is also true of the Great Northern Development Co.'s properties on the Kotsina and Kennecott rivers, in which James J. Phillips, Jr., of New York, is largely interested. These properties are being patented, and over half a million dollars has already been expended in developing an enormous body of ore ranging from 3% to 8%. If the government would permit the coal of Alaska to be used for smelting purposes, this property would be a big producer. Development work is still going forward on the Hubbard and Elliott copper properties on the Kotsina. The Alaska Copper Corporation, which owns the Rarus and Nugget groups of claims on the Kuskalina, Alfred B. Iles, superintendent, is arranging for transportation to connect with the C. R. & N. W. R. R. at Strelna. The California-Alaska Mining & Development Co., A. E. Lathrop, manager, has proved its copper properties in the Kotsina, and is patiently awaiting the construction of a railroad into this district before beginning active mining operations. There are 18 claims in the group.

The Nabesna district has been thoroughly examined by representatives of the Alaska Syndicate this season. Henry Bratnober, the veteran mining man of Alaska, had been developing claims here for the past six years. Its future development wholly depends upon transportation. Should a government railroad reach the area, it will open the largest field for tonnage in Alaska outside of the Kennecott district.

The placer fields of the Nazina district show much more activity this year than ever before. George Max Esterly and Ham S. Andrus have two hydraulic plants fully equipped and in operation, one on Chittitu creek and the other on Rex gulch. Both are driving into a 42-in. flume, with two 4-in. giants, and using a 5-in. giant for stacking tailing. Up to August 1 they had moved more yardage than in any one year since they began operations, and a good clean-up is promised. Forty-two men are employed. H. G. Birch is operating a similar plant on Dan Creek Mining Co.'s ground on Dan creek and using 25 men. This is the first year's active operation on this property, and a very fine showing was made up to August 1. Bert Carvey is operating a small plant and working four men on the bench gravel of Rex gulch and taking out gold. George W. Brooks has a small hydraulic plant in operation on No. 14 Rex, using ten men and mining good gravel. This is the first year's operation of this plant. Coppis, Kernan, Taylor, Stanton, and Sorenson are shoveling in on Chittitu, Rex, and White creeks, using a few men each, and all doing well. Cliff Cayantte has struck good gravel on the bench ground on Dan creek. He is using five men shoveling in and is taking out from $300 to $400 per day per man, according to current rumor. This man deserves great credit for tenacity, having held this property for the past ten years, working in the summer to get a grub stake, and in the winter driving a tunnel in order to tap what appeared to be an old channel. This year he succeeded in running the tunnel through, and is now getting his reward. Murray and Stevenson are building a small hydraulic plant on Young creek, another tributary of the Nazina, and claim to have pay ground. De Witt, Balduff and Maxwell are sluicing on Reader gulch, and Erickson on Upper Young. As was said, much more activity is displayed in this district this year than ever before since the discovery of gold in 1902. Work will continue at least until October 1, and the output is variously estimated by the operators from $350,000 to $750,000.

The Chisana district has not developed into the producer that was hoped or expected. Still, it has not had a fair chance. Provisions were scarce, the proper machinery lacking, and no real prospecting done. The total output will be close to $200,000, and it is believed by those best posted that with proper machinery and intelligent work, this district will become a large producer. Surely there is nothing more discouraging in this camp than was encountered at Fairbanks the first two or three years, except the lack of transportation, Fairbanks having had the advantage of the two large rivers, the Yukon and the Tanana. But should the government railway be constructed so as to tap the Nabesna copper district, this would be overcome. The situation throughout this part of Alaska is very encouraging, and large development is looked for in the next few years.

JOHANNESBURG, TRANSVAAL

TRANSVAAL TIN-MINING INDUSTRY SUFFERS FROM LOW PRICE OF METAL.—ALBU GROUP OF MINES.—MESSINA COMPANY'S AFFAIR.

The low price of tin during June caused some uneasiness to the holders of tin shares in this state. That month's price of Straits tin was £136 or so per ton, compared with £202 last June, and £228 in January 1913. The Transvaal tin-mining industry is comparatively new, but its history is an interesting one, and the losses incurred in speculating in tin properties have been abnormally heavy. Practically the whole of the tin concentrate produced in South Africa is shipped to the Straits Settlements. The output during May was 319 tons valued at £25,956. Owing to the patchy nature of the tin deposits, it has taken several years to establish the industry in the northern Transvaal, where most of the tin mines are situated. It has been suggested by the *South African Mining Journal* that, considering the low price of the metal the mines ought to close down.

In common with all mining groups on the Rand, the experience of the Albu group, or General Mining & Finance, as it is called, has been disappointing during the past year. Controlling some important properties, extending from one end of the Rand to the other, this corporation has always faced the mining difficulties encountered by its subsidiary companies with more than ordinary boldness, and rendered more liberal assistance than many of the other controlling groups. Mines operated by this Company include the New Goch, Roodepoort United Main Reef, Cinderella Consolidated, Rand Collieries, Meyer & Charlton, Van Ryn, and West Rand Consolidated.

Some startling revelations have been made to the shareholders of the Messina Development Co., owner of the well known Messina copper mine in the northern Transvaal, by the report of Price, Waterhouse & Co. of London on the affairs of the Company. Some time ago the failure of Chaplin, Milne, Grenfell & Co. and the Canadian Agency were announced, but little was it expected that the Messina company would be involved in the failures. It now appears that it has discounted bills accepted by the defunct firms amounting to £71,000, and that arrangements have had to be made with the National Bank of South Africa to enable the Messina company to meet its present financial requirements. Loans to the Canadian Agency amounting to £183,000 have been made by the Messina against various securities, some of doubtful value, and to most of the shareholders the disclosures have come as a great shock. The Messina is the only copper mine at work in the Transvaal, and considerable capital has been expended in making a railway to the mine. The mine is situated in the northern extremity of the state, above Pietersburg, not far from the Rhodesian frontier, and unlike other copper lodes in that neighborhood, metal contents continue to a fair depth.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

After September 15 the postoffice at Chisana was closed, in spite of protests of the governor and residents of the district. About 150 people will winter there. Gold output so far is placed at between $250,000 and $300,000.

Juneau

The Alaska Treadwell 240 and 300-stamp mills worked 30.74 and 30.62 days, respectively, in August, crushing a total of 81,596 tons of ore. Gold saved by amalgamation was $155,636, and by cyaniding 1942 tons of concentrate $157,158, a total realizable value of $309,666, an average of $3.83 per ton. Operating expenses were $81,575, and construction $11,590, leaving a net profit of $216,501. Mine development amounted to 530 ft., and the stock of broken ore decreased 54,387 tons.

Nome

The Bangor dredge is in operation. W. W. Johnson, of the Union Construction Co. of San Francisco, has been in charge of construction.

Port Wells

The Granite mill was shut down for 19 days in August, on account of repairs to the concrete foundation. Gold from the plant worth $14,000 was taken to Valdez early in September. The output is now about $1000 per day.

ARIZONA

Cochise County

The Copper Queen smelter at Douglas is to receive custom ores again in a few days, while it is probable that the Calumet & Arizona plant will do likewise. The Warren mining district shows marked improvement of late.

A meeting of creditors of the Tombstone Consolidated Mines Co. is to be held in Bisbee on October 7, when the final report and dividend from this bankrupt concern will be discussed. The property now belongs to Phelps, Dodge interests.

Gila County

The administrator of the estate of F. L. Dupen, who was killed in the Miami mine last June, is suing the Company for $60,000.

Greenlee County

As the Shannon Copper Co. has sold no copper since July 30, the mines and smelter have been shut down indefinitely. The properties produce about 750 tons of ore per day and 1,000,000 lb. of copper per month. Over 500 men are employed. Old employees are offered Company's houses free of rent.

CALIFORNIA

The total value of all mineral products of this state last year was $100,791,369, against $93,219,149 in 1912, according to the U. S. Geological Survey. Some of the principal yields were as follows:

Product.	1913.	Value.	1912.	Value.
Oil, barrels	97,788,525	$45,709,400	87,268,536	$39,616,387
Gold, fine ounces	987,187	20,406,958	953,639	19,713,478
Cement, barrels	6,018,262	8,896,734	6,093,790	8,215,894
Copper, pounds	34,575,007	5,359,126	33,451,672	5,519,526
Clay products	.....	5,344,958	.....	5,912,450
Quarry products	.....	4,118,935	.....	3,902,313
Borax; asphalt	.....	3,200,000	.....	.....
Natural gas	.....	1,883,450	.....	1,134,456

California is first among the states west of the Mississippi river and fifth among all the states in value of its mineral production.

Oil production of California in August was 9,034,853 bbl. from 5984 wells, an increase of 65,158 bbl. over July. Shipments amounted to 7,971,224 bbl., a decrease of 300,000 bbl. compared with July. Stocks were 54,018,481 bbl. on September 1, against 52,954,852 bbl. on August 1.

Amador County

(Special Correspondence.)—For the first time in the history of California, a first-aid contest was held at the picnic grounds, between Sutter Creek and Jackson, on Labor Day, September 7. Teams were entered from Amador City, Sutter Creek, and the Kennedy mine at Jackson. A team also started from Plymouth, but owing to an automobile break-down did not reach the grounds in time to participate. Results of competitions were as follows: first prize, Kennedy team, $65 cash, general average of team, 99%; second, Amador City, $30, average 97%; and third, Sutter Creek, $20, average 94%. The Kennedy mine team was composed of the following: H. E. Stewart, captain, R. White, Wm. Dougherty, Gordon Ireland,

TEAM FROM KENNEDY MINE WHICH WON FIRST PRIZE, AT LEFT; TEAM FROM KENNEDY MINE ILLUSTRATING METHOD OF PREPARING MAN WITH INJURED SPINE FOR TRANSPORT ON MINE CAGE, IN MIDDLE; AMADOR CITY TEAM AT WORK, AT RIGHT.

John Church, and Nick Snell. Amador team: L. C. Cain, captain, O. Anderson, Williamson, I. Brown, E. Worth, and D. Kelley. Sutter Creek team: Henry Loge, captain, Wm. White, Gustave Schroder, Fr. Gehirohi, James Jury, and W. R. Forbes. The judges were Dr. Gall, Dr. Endicott, and S. E. Robbins. Contributions to prizes were as follows: Miner's union, $50; Mr. O'Brien, superintendent of Original Amador mine (for winning team), $20; Kennedy mine, $5; Argonaut mine, $5; South Eureka mine, $5; Central Eureka mine, $5; Keystone mine, $5; Bunker Hill mine, $5; Treasure mine, $5; Fremont mine, $5; and Plymouth mine, $5; a total of $115. The contest was a part of the program at the miners' picnic. It was watched by a large crowd of interested spectators who favored the contestants with much good (?), if unsought, advice, and seems to have aroused more interest in 'first aid to the injured' work than has ever been stirred up in the state.

Jackson, September 19.

A spirited drilling contest was held at Jackson on Labor Day, but owing to the soft character of the rock the local champions' drill stuck at the tenth minute of the fifteen.——Rescue-car No. 5 of the U. S. Bureau of Mines is to be at Jackson from September 28 to October 5. It is now at Colfax.

The Bunker Hill company paid its monthly dividend of $5000 last week. This makes $45,000 for the current year and $746,000 to date. Work at 1950 ft. is encouraging.——The Fremont Consolidated also paid $4000, making $36,000 for 1914 and $254,000 since starting.——The Brunswick Consolidated company has declared dividend No. 5, of 6%, or 6c. per share, amounting to $23,717, payable October 15. This makes a total of 27c. per share in dividends paid by the Company and 18c. per share paid in 1914. The total authorized capitalization is 500,000 shares of the par value of $1 per share, and the total number of shares issued is 395,287.

Placer County

The Placerville Gold Mining Co., an English concern, was operating the Pacific mine at Placerville before the war, but has since leased it to P. D. Burtt and J. H. Santo. The mine has had a good record for production.——The Church Union quartz and placer mines may be reopened soon, as a writ of attachment has been released.

Plumas County

At the Bellevue gravel mine on Wallace creek near La Porte, 10 men are washing tailing, which will take several weeks yet. A 3400-ft. adit was being driven when the war started, Scotch people being heavily interested, but they have decided to continue work.——Eight men are employed at the Motor gravel mine, near Port Wine, and gravel will soon be extracted.

Shasta County

It is reported that 18 ft. of manganese ore has been discovered near Heroult by T. P. Peterson of Redding. It is just across the Pit river from the Noble Electric Steel Co.'s smelter.——No furnaces are in blast at the Mammoth plant, owing to a general overhauling of the bag-house, and building of new tracks about converters, and additional cooling pipes for fume.

Sierra County

A pipe-line is being constructed for the Wide Awake gravel mine near Downieville, to wash some good ground opened. ——Twelve men are at present employed at the Miners' Home mine at Howland Flat.

Trinity County

Twelve men are prospecting the Paulsen ranch, near Lewiston, for dredging purposes.——The Trinity Asbestos Co. has the installation of machinery for its new plant, 27 miles from Carrville, well under way. The first unit will have a capacity of 50 tons of asbestos per day. A large tonnage of ore is available. Oakland people are heavily interested.

Tuolumne County

(Special Correspondence.)—A new company has become interested in the Atlas mine, near Tuttletown, and operations have been resumed. The one-mile adit being driven to cut the workings of the Springfield Tunnel & Development Co.'s property is in over 1600 ft., and better progress is being made owing to a more favorable condition of the rock formation. Development has been in progress for several months at the Louisiana mine, near Tuolumne, and prospects are good at this time. A rich development has just been made on the 700-ft. level of the Providence, southeast of Tuolumne, which has for the past few years been operated by the New Providence Gold Mining Co. The extent of the new orebody is not yet known. The rock is speckled with gold, besides containing high-grade sulphide.

Sonora, September 12.

COLORADO

Gilpin County

Lessees in the Carr mine are doing fairly well, as is shown by the following table of recent shipments:

Lessee.	Tons.	Gold, oz.	Silver, oz.	Copper, %.
Boyd and Co....	4½	2.75	6.77	6.20
Boyd and Co....	2	2.60	5.40	3.00
Holmes and Co...	3½	2.22	8.03	7.73
Eatwell and Co..	3½	3.78	5.90	3.65
Terrill and Co...	2½	1.50	3.50	1.35
Curnow and Co..	3½	2.00	4.00	6.60
Holmes and Co..	6½	1.70	5.00	6.00
Sylvester and Co.	5¾	1.98	3.68	2.00
Williams and Co.	9½	1.11	3.23	1.10

The last three on the list represent concentrate from the Stroehle plant.

Gunnison County

The Good Hope gold mine at Vulcan is being unwatered, and mining is to be resumed. The shaft is down 700 ft., and good ore is said to exist above this point.

Saguache County

Rich gold-bearing ore is reported to have been discovered on the Baca land grant, near Crestone, recently thrown open to prospectors. B. F. Tripton, of Cripple Creek, is in charge of the mineral area of the estate.

Teller County (Cripple Creek)

Practically all of the Cripple Creek holding corporations with producing companies are taking advantage of the ruling of John W. Sheafor, district judge, relative to becoming coplaintiffs with the Granite and Vindicator companies in the suit decided in their favor. On September 12 the Gold Dollar, Petrel, Gold Sovereign, and Pharmacist companies filed their petitions. Under the judge's ruling, the assessment on producing mines will be reduced 3.33 mills, the determined illegal over-assessment.

There is said to be a shortage of cyanide for some mills in the district, especially the Neville, Wild Horse, Isabella, and Gaylord.

Work has been resumed on company account at 1100 ft. in the Gold Coin shaft of the Granite company, which is situated in the centre of the town of Victor. Dan McCarthy is superintendent.——Ore containing about 5 oz. gold per ton has been shipped from 1100 ft. in the South Burns shaft of the Acacia company.——The Gaylord plant is working again. August returns were $3600.——Development in the Elkton is decidedly encouraging of late.——About 700 tons of $20 ore is being extracted from the Abe Lincoln mine per month by Hahnewald Leasing Co., and eight sets of sub-lessees. Prospects are good.——The Cresson Consolidated has taken over the Maggie properties.

The annual report of the Jerry Johnson Gold Mining Co. has been published. All ore mined has been from old stopes:

at 300, 400, and 450 ft. The only encouraging development is the opening of good ore 500 ft. from the main shaft. A total of 3369 tons of ore was shipped worth $78,672. Freight and treatment cost $21,942. Royalties received were $14,057. At August 31, 1914, the cash balance was $30,727. The mine is under lease to Frank Caley up to January 1, 1919, provided he erects a 50-ton mill by the beginning of 1915.

MICHIGAN

Houghton County

The Michigan College of Mines is offering special short courses for miners, millmen, and smeltermen, which is something new for this institution. Regulations for entrance are few.——Excellent progress is being made in cross-cutting in the South Lake mine, records of 55 and 60 ft. being made in five days respectively, and 200 ft. for the past month. Average distances driven in this district are from 130 to 150 ft. per month.——In testing about 10,000 tons of 'rock' from the Franklin's Allouez conglomerate lode at the Allouez-Centennial mill, a recovery was made of 14 lb. of copper per ton. Loss in tailing was nearly 7 lb. per ton.——After spending over $2,000,000 in exploration, the Winona company's mine is filling with water.

MISSOURI

Jasper County

Heavy rains have flooded a number of mines during the past week. The East Hilltop mine of the Oronogo Circle company was badly damaged.

MONTANA

Fergus County

Estimated gold yield of the Barnes-King company in August was $27,400 from 4200 tons of ore, with $10,000 profit.

Silverbow County

At its 11 operating shafts the Anaconda company has 2800 men on night and 3000 on day shifts.

NEVADA

Clark County

Rich gold ore from the Boss mine of the Goodsprings district is reported to contain high platinum content, and is confirmed by Ledoux & Co. of New York and the U. S. Geological Survey.

Elko County

(Special Correspondence.)—Mill tests which the Eastern Star Mining Co. has been conducting in San Francisco have been completed, and it is announced that a 10-stamp cyanide mill will be built, construction to start as soon as the surveys can be made and mill plans drawn. The mine is in the Gold Circle district in the western part of the county. The tests were conducted by the California Ore Testing Co. under the supervision of W. B. Chidester, who will have charge of mill construction for the Eastern Star Mining Co. The tests show an extraction of 96.2% gold and 84.4% silver, a total extraction of 94.5%, in a 24-hour treatment, crushing in solution. The capacity of the mill will be about 60 tons per 24-hour day.

Gold Circle, September 18.

Humboldt County

About a half-mile per day of the new line into Rochester is being laid, according to A. A. Codd, and less than six miles remains to be completed. The 60-hp. engine and frame of a Winton automobile was placed on light railroad trucks and acts as a locomotive to haul material for the line.

Contracts have been let for the complete mill of the Rochester Consolidated Mining & Milling Co. It is of 100-ton capacity and is to contain the following machinery: Blake jaw-crusher to crush 100 tons in 8 hours, ten 1550-lb. stamps of Allis-Chalmers manufacture, who also supply other machines; Dorr classifiers, two 5 by 18-ft. tube-mills, Dorr thickeners, Dorr agitators, Dorr continuous decantation system, zinc-boxes, and sampling plant. All will be motor driven from the Nevada Consolidated Power Co.'s plant. Back-geared motors will be used to drive the stamps.

There are no troubles with gas now in the Seven Troughs Coalition mine. The daily output of ore is 40 mine-cars assaying $100 per ton. Ore at 1200 ft. is still high grade.

Lyon County

Ore received at the Mason Valley smelter during the week ended September 16 totaled 2461 tons, of which 1870 tons was from the Mason Valley mines, and 389 tons from the Nevada-Douglas. A rumor that the plant was to be stopped is without foundation.

Mineral County

At a distance of 4400 ft. from the mouth of the adit, rich silver-lead ore has been opened for 130 ft. in the Lucky Boy property at Lucky Boy. This is at a depth of 600 ft. vertical. The adit is to be continued to the Hubbard shaft, about 1400 ft. ahead of the present face, and all virgin ground. Stoping is to be started on the orebody.

Nye County

At 200 ft. in the White Caps, at Manhattan, the lode is 24 ft. wide, averaging $20 per ton. A raise in this shoot shows higher grade ore. Oxidized ore ready for treatment is worth $40,000.——A new system of handling ore from the Big Pine open-cut is now in operation. A Blake crusher is working at the collar of the main shaft, and breaks ore hoisted from 200 ft., to where it is dropped from the open-cut, where two men mine 200 tons per day. After passing over grizzlies, the oversize, assaying 60c. per ton, is trammed to the waste dump, representing 48% of the total product. By this means the ore milled is three times the value of the ore before separated by crushing and screening. Tests are being made to see if the ore cannot be sent direct to a tube-mill from the crusher, eliminating the stamps.——Sampling and testing at the Commercial mines has been suspended temporarily. Only two 200-ft. holes were drilled.

Tonopah mines produced 10,094 tons of ore, worth $207,680, during the past week. In August the Belmont yield was 315,286 oz. bullion from 15,455 tons, with a profit of $128,582. ——The Tonopah Mining Co. produced 227,610 oz. silver and 69 tons of concentrate from 11,970 tons of ore, with $84,020 profit.——Jim Butler profits were $20,951 from 4096 tons. Profits for the year total $199,921.

NORTH CAROLINA

Montgomery County

The property of the Candor Mines Co. has been bought by the Martha Washington company, which is developing the adjoining property, and will use the Candor mill for treating its ore. The Candor mine is now shut down, and operations in the Uwarra are at a low ebb.

UTAH

Juab County

A large cave-in in the Centennial-Eureka mine on September 17 resulted in 12 miners being buried. Rescue work was difficult.——No ore is to be shipped from the Grand Central mine until the market improves, but development continues at 600, 800, and 1000 ft., also shaft repairing.——Machinery is arriving for the new concentrating plant of the Chief Consolidated mine.——To treat the lower grade ores of the Victoria mine, the manager, J. C. Lynch, states that a mill and cyanide plant may be erected next year.

Salt Lake County

The Ohio Copper Co.'s property is in the hands of receiv-

ers, and the mine and mill have been closed indefinitely. About 250 men are affected.

SUMMIT COUNTY

Work at the Daly-Judge mine and mill was resumed on September 18 and 20. The main shaft has been retimbered in places, development done, and the mill overhauled.

WASHINGTON

FERRY COUNTY

The Lone Pine, Pearl, and Surprise mines of the defunct Republic Mines Corporation are now controlled by West Virginia people, and J. L. Harper and other Spokane associates. The properties are under a three-year bond for $200,000, $10,000 having been paid. The San Poil mill is also to be taken over under a four-year bond for $185,000. The new syndicate is negotiating for the Last Chance and other claims at Republic.

CANADA

BRITISH COLUMBIA

The Standard Silver Lead Mining Co. has cut its monthly dividend for September to 1¼c. per share, corresponding to a dividend of $25,000, making $1,550,000 paid since April 1912. Shipments are now suspended, and the earnings in July were only $30,550, as only 25c. per ounce has so far been advanced on silver. The cash on hand at July 1 amounted to $226,315.

ONTARIO

The Nipissing company produced silver worth $212,965 in August, but only shipped $69,855, the balance being stored at the mine. Prospecting by hydraulicking revealed a vein of low value. Vein 98 is now 540 ft. long and 65 to 80 ft. high. The Little Silver branch vein at shaft 63 is 2 in. wide, assaying 2500 oz. per ton. The Company is being sued for $5000 by A. Brazeau, who alleges that he was injured in the mine this year. Development at the Teck-Hughes at Kirkland Lake, which the Nipissing has under option, has opened a vein parallel to the main orebody.——During the first 18 days of August the Alexo mine shipped a total of 564 tons of nickel ore to the Mond Nickel Co. at Coniston.

MEXICO

(Special Correspondence.)—A scarcity of labor is retarding extensive mining, milling, and smelting operations in the state of Chihuahua, according to recent reports. Recruiting for the army of General Francisca Villa, which was carried on up to a short time ago, is said to be principally responsible. However, it is expected that many Mexican laborers will now return to Chihuahua districts from copper centres of the United States, where operations have been curtailed. The Chihuahua smelter, one of the American Smelting & Refining Co.'s plants, is operating only two furnaces. While in San Francisco recently, R. M. Raymond, director of the Exploration Co., Ltd., London, stated that the El Oro Mining & Railway Co., one of the concerns controlled by the Exploration company, would be soon operating again on a large scale. He said that the Company was fortunate in having on hand a large supply of cyanide, shipments having arrived after operations were suspended. It is understood that some of the other important mining concerns of Mexico also have plenty of cyanide in stock as a result of the arrival of shipments during the late trouble. No arrangements have yet been made for the resumption of work at the Zacatecas camp of the Santa Rosa Mining & Milling Co., another concern controlled by the Exploration company. Pachuca and Guanajuato companies are resuming work in those districts. In the state of Jalisco, the Amparo and Cinco Minas companies are operating in a limited way, and work probably will be in progress soon at the Casados, El Favor, Mololoa, Espada, and Amajac camps. A decision to resume mining and milling has been reached by the American company owning the Lluvia de Oro gold mine in western Chihuahua. This Company maintains its shipping agency at San Blas, on the Southern Pacific Railroad of Mexico. T. H. Pomeroy, an oil man from Tampico, who arrived here a few days ago, reports that lightning recently fired a lake of oil at the big Potrero del Llano gusher of the Pearson interests south of Tampico, and that when he left that Mexican port the destruction of the well was feared. The Dos Bocas well, the first large gusher brought in by the Pearson interests, was burned out a few years ago. The Potrero del Llano was credited with a capacity of 100,000 bbl. daily, and was the greatest gusher of the Tampico before the Corona.

San Francisco, California, September 21.

Direct trains between Mexico City and El Paso, Texas, without stopover or change of cars by passengers, were started by the Constitutionalist authorities on September 9. They were interrupted September 23 on account of threatened trouble with Villa, whether temporarily or not is uncertain. *The Mexican Herald* came through from Mexico City to San Francisco, California, in 7 days. The service from the capital to Nuevo Laredo, Tamaulipas, was resumed September 12. Also a service from the capital to Manzanillo and Guadalajara, with a change of cars at Colima. The line from San Luis Potosi to Tampico is in working order; and repair work between San Francisco and Vera Cruz is nearly finished. All is quiet in the states of Tepic and Sinaloa, and work is being resumed by some Americans and other foreigners. Coal mines in Coahuila are being operated again, and damaged towns are being repaired. Federal troops are being disbanded by the Constitutionalists. Military passes are not required by persons leaving Mexico City, save officers of the former federal army. Prices of corn and sugar have been lowered, and a fine will be inflicted on attempts to sell above the fixed price. On September 13 there was a great demonstration in honor of the late President Madero. His clothes are now in the Museum. *Bonos* or treasury notes issued by Carbajal are to be withdrawn from circulation, and ₱5,000,000 of Constitutionalist notes in 10, 20, and 50 *centavos* have been circulated. Business with New York has been done at 20 to 25c. per *peso*. There is still a disturbance in Sonora, and Villa with an army of about 5000 men is to proceed against Governor Jose Maria Maytorena and Gen. Benjamin Hill who renounced the Carranza government. After this campaign, part of the army will move against former federal garrisons in Lower California who have refused to surrender.

MAP OF MEXICO.

PERSONAL

C. A. Rodegerdts has gone to Mazatlan.

Address of B. Frank Hand is wanted.

Karl Eilers returned from Europe on September 16.

C. R. Corning has returned to New York from Bolivia.

Stephen Birch has returned to New York from Alaska.

Morton Webber has gone to Porcupine on professional business.

Gelasio Caetani left for Rome Friday. He hopes to return in February.

R. E. Hore is soon to be married to Miss Morrison at Calumet, Michigan.

Donald F. Irvin sailed September 15 from Boston for Costa Rica *via* Havana.

James Whipple is in the hospital at Los Angeles suffering from stomach trouble.

A. W. Geiger is back from Eagle River, Alaska, and has been in Trinity county.

Ralph Stokes, who returned to England to join the army, is a veteran of the Boer war.

Alton L. Dickerman is at Houghton, Michigan, after an extended trip through the East.

E. C. Morse is now superintendent of the mill at the Ogie Mt. mine, at Scotts Mills, Oregon.

J. Kojima, metallurgist for the Ashio Copper Co., is expected to arrive in New York early in October.

Richard L. Grider is making an examination of placer properties on the Tipanni river, Bolivia.

George H. Garrey is at present making a geological examination of zinc-bearing lands in Tennessee.

C. M. Eye will sail for Manila on the *Manchuria* today, the sailing of the *Minnesota* having been canceled.

Theodore J. Hoover is on his way to California, where he expects to stay a few weeks, returning to New York.

Heinrich Ries has returned to Cornell from Europe, where he visited the iron deposits of Lapland and the mineral districts of Bohemia.

H. M. Zeisemer and F. B. Anderson, consulting engineers for the Copper Queen, recently examined the Commercial holdings in Copper Basin.

Owing to interruption of steamer schedules by the war, Ferdinand McCann went to Mexico from Hong Kong by the Japanese line instead of to the Argentine by way of the Suez.

J. M. Callow, president of the General Engineering Co., of Salt Lake City, left last week for Miami, Arizona. He will go from there to Superior to inspect the Magma Copper Co.'s mine.

Arthur L. Walker is returning to America from Kyoto, having decided to cancel his trip through Korea and China, on account of the war. He will visit smelting plants in the western United States before returning to New York.

John R. Stanton has been elected president of the Mohawk and Wolverine mining companies, succeeding Joseph E. Gay. Frank M. Stanton succeeds his brother as treasurer of these companies, and G. W. Drucker has been succeeded by J. W. Dunston as director of the Mohawk, but the vacancy has not been filled in the Wolverine.

The American Institute of Mining Engineers will hold its next annual meeting in New York City, beginning February 16, 1915. Papers for this meeting should be with the secretary not later than November 23.

The American Mining Congress will meet at Phoenix, Arizona, from December 7 to 11, inclusive.

SOCIETY MEETINGS

Obituary

Caradoc James, well known in Western Australia and London, and recently metallurgist at the Tarquah mine, West Africa, died at sea in July on his way to England from Africa. He had been in that territory for several years, with the usual long vacations necessitated by the climate.

C. A. Stewart died on August 28 at Westhampton, Long Island, following several operations which he had undergone in the spring. He was a graduate of Columbia and Cornell universities, having taken his Ph.D. in geology at Cornell. He was later appointed professor of geology in the State University at Idaho, where he did notable work and had made much progress toward securing the establishment of a state geological survey. Last spring the state of his health made it necessary for him to come to New York to undergo an operation, a second proved necessary, and he did not recover from its effects. He was one of the most brilliant of the younger geologists, and if his life had been spared a few years more he would have made a notable mark in his chosen profession. He leaves a widow, to whom the sympathy of his many friends is extended.

James Porter Evans died suddenly of pneumonia at his home in Denver on Sunday evening, September 13. He was born at Zanesville, Ohio, November 29, 1860, and went to Denver in 1881 to engage in the railroad business, rising through various positions to that of auditor for the Denver & Rio Grande railroad. In 1895 he went to the Colorado Iron Works Co., of which he was vice-president and general manager at the time of his death. His activities in connection with the development and manufacture of mining and smelting machinery brought him into intimate contact with many men of note, and in his sudden demise the mining industry loses a prominent figure. Mr. Evans had drawn to himself a wide circle of friends to whom he had endeared himself through his upright character and genial disposition. Upon these his loss will fall as a personal bereavement. He was a member of many societies, among them the American Institute of Mining Engineers. He is survived by his widow and one daughter, Elisebeth.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, September 24.

Antimony	15 —15¾
Electrolytic copper	13⅝—13⅞
Pig lead	4.00— 4.95
Quicksilver (flask)	$75
Tin	36 —37½
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	15

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, September 24.—The metal markets are quiet, there being none for copper, while lead and spelter are quoted at 3.85 and 5c. respectively. Dividends declared are as follows: Old Dominion, 25c. per share on October 8; Old Dominion Copper Mining & Smelting Co., and United Globe Mines, both controlled by the Old Dominion of Maine, $2.25 and $3.50 per share, respectively, on October 7; International Nickel, 1½% on preferred and 2½% on common, on November 1; Eagle & Blue Bell, 5c., on October 1; Consolidated Mining & Smelting Co., of Canada, 2%; and Anaconda Copper Mining Co., 25c., against 75c. last quarter. Exports of manganese from Russia have been prohibited, except to Allied nations. The steel trade is dull, and as a whole only 60% of mill capacity is being operated.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The average price of bar silver in London in August was 25.979d., or 51.958c. per ounce. The market is unchanged there at about 24¼d., and nearly all buying at present is confined to coinage orders. Stocks in Bombay are now 6000 bars. Writing on September 10, Samuel Montagu & Co., of London, state that the tone of the market has improved somewhat, due to decreased supplies from America. Regarding trade demands, the metal is a drug on the market. Imports of silver into London up to this date were 60,420,385 oz., compared with 79,561,836 oz. in the same period of 1913.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per pound more. Prices are in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	....
Mch.	14.72	14.11	Sept.	16.23	....
Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

The New York market continues stagnant, and foreign market easier. Prices range from 12 to 12.5c. per pound. Exports for the month, up to the 23d, total 11,897 tons. England takes copper in increasing quantities, but naturally most of the shipments made are on bookings previous to the war.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Week ending	
Aug. 27	80.00	Sept. 10	75.00
Sept. 3	75.00-85.00	" 17	75.00
		" 24	75.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	....
Mch.	40.20	39.00	Sept.	39.70	....
Apr.	41.00	38.90	Oct.	39.37	....
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

There is no change to report in this metal. Large orders would pay a somewhat lower price than the above quotation. In the last 'Press Bulletin' issued by the U. S. Geological Survey is given a general summary of the quicksilver situation, covering production, uses and prices, most of which has been published in the 'Press' from time to time.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Sept. 17	3.85	Aug. 12	3.85
" 18	3.85	" 19	3.88
" 19	3.85	" 26	3.87
" 20 Sunday		Sept. 2	3.90
" 21	3.85	" 9	3.85
" 22	3.85	" 16	3.85
" 23	3.85	" 23	3.85

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	4.28	4.11	July	4.35	3.80
Feb.	4.33	4.02	Aug.	4.60	3.86
Mch.	4.32	3.94	Sept.	4.70	....
Apr.	4.36	3.86	Oct.	4.37	....
May	4.34	3.90	Nov.	4.16	....
June	4.33	3.90	Dec.	4.02	....

St. Louis quotes are 3.60 to 3.62½c. per pound, with slow sales.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
Sept. 17	5.00	Aug. 12	5.25
" 18	5.00	" 19	5.60
" 19	5.00	" 26	5.77
" 20 Sunday		Sept. 2	5.75
" 21	5.00	" 9	5.50
" 22	5.00	" 16	5.25
" 23	5.00	" 23	5.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	6.88	5.14	July	5.11	4.75
Feb.	6.13	5.22	Aug.	5.51	5.45
Mch.	5.94	5.12	Sept.	5.55	....
Apr.	5.52	4.98	Oct.	5.22	....
May	5.23	4.91	Nov.	5.09	....
June	5.00	4.84	Dec.	5.07	....

St. Louis wires that immediate demands seem satisfied and the market is dull. Ore, basis of 60% metal, is down to $44 per ton. Buyers' orders are easily filled. Exports from New York since August 18, when the movement started, total 11,000 tons.

TIN

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	....
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

The nominal price of Straits tin in New York is about 31.75c. The market has only a limited number of sellers. Deliveries up to September 17 at Boston, Baltimore, and Philadelphia totaled 2902 tons, and metal afloat and due by the end of the month is 1815 tons.

MINING DECISIONS

Oil and Gas Lease—Lessee in Wrongful Possession

Where a lessee under an oil and gas lease brings in a gas well after the term stipulated in the contract of lease has expired, he will not be held for exemplary damages where it is shown that he acted in good faith, and under the advice of competent counsel, and before suit was brought.

Cooke *v.* Gulf Refining Co. (Louisiana), 65 Southern, 758. May 25, 1914.

Coal Mines—Width of Barrier Pillars

The Pennsylvania Legislature having provided that the width of barrier pillars between two coal mines should be determined by a tribunal, consisting of the mine engineer from each of the adjoining mines and the district inspector, the finding of such a tribunal that the width of the pillar in a given case should be 300 ft., made by a majority of the tribunal after opportunity for inspection and hearing had been given all the members and parties interested, will not be disturbed.

Mill Creek Coal Co. *v.* Curran (Pennsylvania), 91 Atlantic, 424. March 23, 1914.

Ore on Dump—Realty or Personalty

Whether or not ore extracted from a mine and placed on the dump is realty and a part of the mines or personalty, depends upon the intention of the owner thereof at the time of its extraction. Unless it be shown by the evidence that there was a specific intent on his part at the time to consider the ore as personalty separate from the mine, it will be treated as a part of the realty and pass under a subsequent deed conveying the mine.

Steinfeld *v.* Omega Copper Co. (Arizona), 141 Pacific, 847. July 9, 1914.

Patent Improvements—Not Allowed

The certificate of the surveyor-general as to improvements upon a mining claim required by section 2325, Revised Statutes, is not conclusive upon the Land Department, which may, in the presence of anything tending to impeach the correctness thereof, wholly disregard the certificate and require further showing as to improvements. No part of the value of permanent and immovable improvements on a mining claim, made long prior to the location thereof by the present claimant, under a previous location embracing the same ground, solely to improve and develop the prior claim can be accredited as patent improvements on the latter claim, there being no privity shown between the former and present locator.

C. A. Sheldon *et al.* (Land Department), 43 Land Decisions, 152. February 21, 1914.

Gas Lease—Suit on Implied Covenants

A gas lease provided that a test well should be drilled to completion, and if gas were found in sufficient quantities to be marketable, for royalties to the lessor. The lessees drilled the test well and found gas in profitable quantities, but thereafter neglected to extract the same or drill further wells, or pay royalties to the lessor. The lease provided that the lessee should hold the premises for five years or as much longer as gas or oil should be found in paying quantities. Held, that the lease conveyed, in effect, a freehold estate, and that the lessor was entitled to sue for damages for breach of covenant to extract the gas and pay royalties, and not merely for a forfeiture of the lease.

Doughetee *v.* Ohio Oil Co. (Illinois), 105 Northeastern, 308. June 3, 1914.

BOOK REVIEWS

The Mineral Industry During 1913. Edited by G. A Roush. P. 1010. Ill., index. McGraw-Hill Book Co., New York, 1914. For sale by *Mining and Scientific Press*. Price, $10.

This, the twenty-second volume in the series established by Rothwell, is consistent in general form and scope to the preceding volumes. Its editor, Mr. Roush, who came new to the task this year, is, however, to be congratulated upon having produced one of the best volumes of the series. The individual chapters have been prepared as heretofore in collaboration with many men, and while not of equal value, they are, on the whole, wonderfully consistent and serviceable. The special chapters are: 'Progress in Ore Dressing and Coal Washing,' by Robert H. Richards and Charles E. Locke; 'Hydrometallurgy of Copper,' by Thomas T. Read; 'Analysis of Smelter Contracts,' by Gelasio Caetani (reprinted from the *Mining and Scientific Press*); 'The New International Diamond Caret of 200 Milligrams,' by G. F. Kunz (reprinted from *Trans.* A. I. M. E.); 'Data of the World's Principal Mines,' by S. F. Shaw (reprinted from *Eng. & Min. Jour.*); and the usual summaries by countries.

A Text-Book of Geology. By James Park. P. 598. Ill., index. Charles Griffin & Co., London. J. B. Lippincott Co., Philadelphia, 1914. For sale by *Mining and Scientific Press*. Price, $4.50.

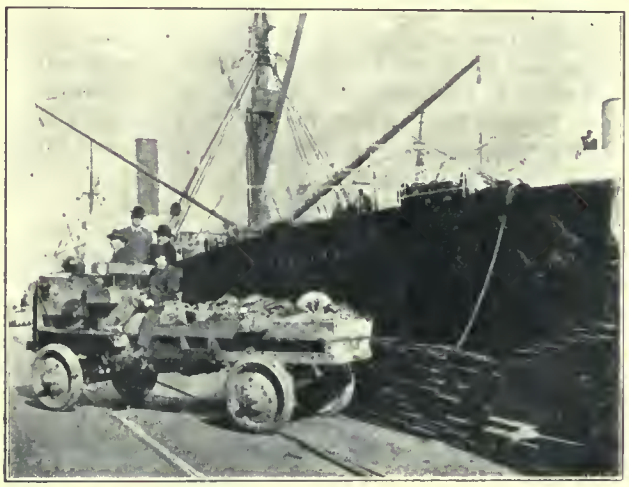
In the introduction to this text-book the veteran professor of geology in the University of Otago, gives some excellent advice to the student entering upon the subject. In particular, he says: "Make an early acquaintance with the facts of geology as presented in the field. Miss no chance of travel or exploration with the experienced geologist. Cultivate the faculty of exact observation, and be mindful not to form hasty conclusions. Remember that things are not always what they seem. Make extensive collections of rocks and fossils, and be careful to keep the fossils of each horizon apart. Take every care to preserve your fossils from injury. The dictum of the Hon. Walter Mantell that 'a fossil that is worth collecting is worth its paper' is as true now as when made to the author forty years ago, and applies equally well to rock specimens. Do not attempt to describe new species; leave that to the specialist. Even when you have gained some note as a writer on geology, refrain from coining new terms. * * * Do not select a single specimen of a rock for analysis and regard it as representative of the whole mass, as the results may be altogether misleading. All sedimentary and igneous rocks vary considerably in composition in different parts, the former because they are mechanically formed, the latter on account of the development of large phenocrysts or the proximity of sedimentary or other rocks. Select fresh unweathered examples whenever procurable, and, except it be any analysis of a particular fragment that is required as an aid to microscopical examination, select the average sample or samples with as much laborious care as you would sample a coal seam or an ore vein. Unless you are a specialist, which is unlikely, do not attempt the analysis of your rock samples; do not think that because you have waded through the analysis of a rock specimen or two in your graduate course that you are competent to undertake the systematic analysis of a rock."

The body of the text follows the usual lines, beginning with a brief résumé of the principles and scope of the science, and continuing through a study of geologic processes to their products, to a brief history of the earth, and closing with brief sketchy chapters on economic geology, field geology, and geological surveying. Illustrations are chosen from a wide field and the book is excellently printed.

New Machines and Devices

Auto-Trucks for Ore Transport

Owing to the war in Europe, the supply of magnesite from Austria was cut off, and some of this mineral from a California mine was brought to tidewater on Jeffery 'Quad' trucks, and then shipped east by way of the Panama canal in the *Nebraskan*. It was thought that when this magnesite mine was opened that it would be necessary to build a railroad over the mountains in order to carry the product out, but by this



JEFFERY QUAD DELIVERING MAGNESITE ORE TO THE STEAMER.

time the United States government had finished its tests of the Jeffery truck, demonstrating the ability of this vehicle to carry a two-ton load anywhere that a four-mule team could pull a load, with the result that this truck was found very suitable for this strenuous kind of transportation.

Commercial Paragraphs

The McCord Mfg. Co., of Detroit, shows in Catalog No. 12 the force feed lubricators of this firm.

The Nordberg Mfg. Co. is distributing Catalogs 23 and 24, descriptive respectively of the steam and air and the electric hoists manufactured by that Company.

The Western Electric Co., of New York, has issued a leaflet describing a new portable vacuum cleaner of the outside bag type, which embodies several improvements.

The Hammond Iron Works have come promptly to the front and are distributing a convenient little map of Europe. Carry it in your pocket and keep in touch with the armies that are fighting.

The Hardsocg Wonder Drill Co. is marketing a new rotating sinking drill which is known as No. 90. It is designed not only for sinking but for block-holing, hitch-cutting, and similar duties.

A. Leschen & Sons Rope Co., of St. Louis, monthly bulletin describes the new state capitol of Utah. During construction of this $2,000,000 structure the contractors used 12,600 ft. of ⅝ in., and 1100 ft. of ¾-in. 'Hercules Red Strand' wire rope, made by this firm.

The Stephens-Adamson Manufacturing Co., of Aurora, Illinois, monthly, *The Labor Saver*, No. 65, is devoted to coal handling machinery in all its uses. Some interesting pictures are shown of screens, elevators, jig driving gears, stokers, bucket carriers, conveyors, and other equipment.

The 'Giant' low-grade fuel oil engine manufactured by the Chicago Pneumatic Tool Co. is described in *Ideal Power* for July. This is designed to stand especially hard service and to burn various crude and residual oils. It is based upon ten years experience in building gasoline engines.

The Senn Concentrator Co., of San Francisco, recently published a booklet entitled 'Senn Pan Motion.' In it are described the standard 8 and 12-ft. concentrators, which have large capacities; and the pan-motion amalgamator, which has a capacity of 50 tons per 24 hours. A description of the pan motion appeared in this column last week. The catalog is attractively gotten up.

The Luitwieler non-pulsating pumps are described in a reprint from the *Engineering Magazine* for August and a series of interesting pamphlets covering the 'Luitwieler System of Pumping,' the 'Luitwieler System of Non-Pulsating Triplex Pumps,' and the 'Luitwieler Non-Pulsating System' issued by the Luitwieler Pumping Engine Co., of Rochester, New York. In these pumps a cam is used to transmit power from the driving shaft to the plungers, and, while the principle is old, the method of application is such as to give a highly efficient machine suitable for many uses around mines.

The National Tube Co., of Pittsburgh, Pa., *Bulletin* No. 9C describes some expansion tests of 'Kewanee' pipe unions. Nine unions, ranging from ½ to 2 in., were connected by short lengths of corresponding size pipe, with a 'regrinding' valve at one end of the pipe. Steam at 140-lb. pressure was turned on for 5 minutes to 92 hours, the fittings thus being heated to the steam temperature at this pressure. Steam was turned off, and the whole immersed in a vat of water of 48°F. temperature for 5 to 30 minutes. This test was repeated 50 times, and the unions held tight after all. Service tests were made of several other unions, these being disconnected 1000 times, showing no leaks.

The G-O riffle, manufactured by the General Ore Concentrating Co., is made from monel metal that unique combination of copper and nickel. It is machine made with great accuracy and its peculiarity is that the points are integral with the riffle itself. As a result there are no irregularities as in the ordinary wooden strip nailed to the deck of the table, and it is possible by reason of this and the hard, true edge presented to secure absolutely uniform results. The riffles are furnished in various sizes and can be fitted to any deck. Not only do they permit better work, but they are quicker placed, and last longer. Therefore they decrease loss of time and so increase plant capacity.

The Ingersoll-Rand Co., of New York, has recently perfected and placed on the market a new type of hoist, known as the 'Little Tugger.' It is intended for light lifts, having a capacity of 1000 lb., and as it only weighs 300 lb. complete, and is 21¼ by 16½ by 20⅛ in., is suitable for mining and other work. Underground it may be clamped to a drill column or stretcher bar, shaft bar, or timber, for hauling various loads. The drum is 6 in. diameter, and will hold 700 ft. of ¼ or 450 ft. of ⅜-in. rope. At a rope speed of 85 ft. per minute, and 80-lb. air or steam pressure, the load is 1000 lb. The motor or engine is of the reversible square piston type, and there are no dead centres.

WAR news must give way this week to editorial discussion of technical matters. We can promise to even the score by a double measure next week of Mr. Rickard's pen pictures of conditions in London.

DEVELOPMENT, production, and construction at many copper mines in the United States have been curtailed somewhat on account of the war, but it is encouraging to hear that work goes on unabated at the Chile Copper Company's great plant at Chuquicamata, and leaching may be started by April next. All seems well at the Braden mine, also in Chile.

PLANS for the meeting of the American Institute of Mining Engineers at Pittsburgh, October 8, 9, and 10, include excursions to the Homestead or McKeesport works, the Harbison-Walker plant, and the testing plant and experimental mine of the U. S. Bureau of Mines. The preliminary list of papers indicates that the technical program will be up to standard and full of interest.

WAR has conferred unusual interest on the papers published in the *Annales de la Société Géologique de Belgique*, of which the volume for last year has recently appeared. Among other studies of regions made familiar to everyone through the daily news reports, M. Ch. Stevens contributes an '*Etude des terrasses de la Sambre*' in which he concludes "*L'inégale résistance des roches à l'érosion a causé ces différences topographiques dans une meme vallée.*" The fierce resistance of maddened human beings to each other's advance has since then imparted an entirely new aspect to that unhappy country.

STEAM STAMPS are discussed at length in this issue. While experience seems to indicate that the heavy stamps find their best field for usefulness in northern Michigan, the old firm of Fraser & Chalmers did build such stamps for the Boston & Montana, the Anaconda, and the W. A. Clark mines in Montana, as well as for the Homestake and for a Japanese mine. The later Allis-Chalmers company, as well as the Nordberg Manufacturing Company, has not attempted to push these stamps except in the Lake Superior country. The Allis-Chalmers company does make a small steam stamp, the 'Tremain,' which has given good account of itself in Rhodesia and various other countries. The reason for this difference in usage is discussed elsewhere.

GERMANY has afforded one of the great markets for copper. Aside from approximately 50,000,000 pounds of domestic production, the Empire has imported about 425,000,000 pounds per year, and of the 100,000,000 or more pounds sent annually to Holland, a large part found its way into Germany. Part of this has been re-exported in the form of manufactured goods and part has evidently gone into manufacture of war material, but the domestic consumption for ordinary uses is enormous. No doubt the demand for copper in the Empire just now is especially large. Great Britain regards copper as conditional contraband and is using every effort to prevent supplies reaching Germany through neutral territory as well as direct, as related on another page. The suggestion, therefore, that American ships load with copper and cotton to Holland, returning with cyanide, dye stuffs, and medicines from Germany involves peculiar difficulties. In ordinary times the North German Lloyd line sailing from Baltimore to Bremen finds in cotton and copper a heaven-born combination of bulk and weight, comparable only to the pig iron and coke of the Scotch and Belgian ships that come to California. In war times, however, the economically sound routing of freight is not always possible, since other conditions must be taken into account.

CONCERNING COPPER QUOTATIONS

Our contemporaries in Chicago and New York, the *Mining and Engineering World* and *The Engineering and Mining Journal*, have been indulging in a discussion concerning metal quotations that has become at times so heated as to threaten losses by volatilization. We have no desire to mix into what is 'a very pretty quarrel' as it stands. However, our friends in Chicago have intimated broadly that the *Journal* quotations are not only inaccurate but are not independent. In this we believe them to be mistaken. The *Journal* is a bit pompous, mayhap, and its assumed superiority, though generally merely amusing, becomes wearisome at times, but it is honest and uncontrolled. If we have occasionally shied a stone at the famous glass house, it has been mainly with an eye to decoration of the landscape through the internal explosion that never failed to follow. Differences in policy, we hope, do not necessarily imply differences in honesty, and the *Journal*, as is true of technical publications in the United States without

notable exception, enjoys a well deserved reputation for honesty and independence.

As to the latter we are privileged to quote the following from a personal letter from Mr. T. A. Rickard: "I note also that the Chicago paper again suggests that *The Engineering and Mining Journal* is controlled by a special interest and that the copper prices are untrustworthy on that account. Well, as you know, I used to have something to do with the *Journal*, and I can testify to you that it was absolutely independent of the Guggenheims or any other financial group, and I am willing to give long odds that it is just as independent now." Coming as this does from one who has served as editor of both the *Journal* and the *Press* and is now editor of *The Mining Magazine*, it voices the opinion of an informed and independent critic.

However, the *World* has shown that there is a discrepancy between the average quotation, as published in the *Journal* and the average sale price as realized by a number of the large copper selling concerns. We believe this is more an indictment of a system than of an individual; but the system is one that obtains generally in trading in commodities and securities. That the *Journal* quotations are as nearly correct as it is practicable to make them, we are satisfied for the excellent reason that careful comparisons ranging over many months and several years, show that they check with our own, of which, as a matter of course, we know the source absolutely. Furthermore, they do not differ materially from the quotations in *The Iron Age*, which has its own market observer, and a very capable one. A large silver dealer tells us that our quotations of that metal are consistently nearer the market than are those of the *Journal*, but in the main the quotations made by the *Press*, *Journal*, and *Iron Age* check closely. They do not agree so closely with those given by *The American Metal Market*, and they are consistently lower than those reported by the Associated Press. The reason for this lies in the fact that the two last named depend largely, if not entirely, upon the New York Metal Exchange, and it is true, if unfortunate, that the big business is not done on the exchange. The condition is not unlike that in San Francisco, where only small lots of metal are bought and sold. Our own San Francisco quotations are therefore always higher as to most metals than our New York and St. Louis quotations. Nobody pretends to think than any considerable body of metal is sold or could be sold at San Francisco prices. The difference between the two sets of New York quotations, while due to the same sort of conditions, is naturally much less.

The quotations published by the *Journal*, *Press*, and *Iron Age* take into account the quantities sold on each day, but this quantitative factor is lost when weekly, monthly, and yearly averages are made, and that is the source of the trouble. Each quotation represents as nearly as possible the price at which copper was sold in quantity on the day mentioned, but the amount sold varies greatly from day to day. For weeks, perhaps, only small lots will change hands, though each day there is a ruling price at which only, large amounts could be bought or sold. That price is the correct price for such copper as is settled for as of that date. The larger companies have, probably, the shrewder dealers, the more complete information, and the better financial backing, which permits them to wait for favorable prices. On the average they sell more of their copper when the price is high than when it is low, and therefore their average return for the year is a trifle above an arithmetical average of entirely honest and fair daily quotations. That is all there is to the matter. As to the intimation that the Guggenheim interests, the Anaconda, or any other group, can fix the price of copper or control its quotation price; it needs but to review the list of dealers and to note the amounts each sell, as printed, for example, in the *Press*, May 3, 1913, to make evident the fact that the copper market is keenly competitive.

Despite the fact that the Guggenheims control more than 60 per cent of the lead production of the United States, there is also keen competition in the sale of lead. It is to be remembered that the largest individual lead-producing company in the world, the St. Joseph Lead Company, is not under the Guggenheim blanket, and that there are other independent sources of supply. The conditions as to lead and copper differ and it is common to name the American Smelting & Refining Company price separate from the general market price when, as happens frequently, there is a slight difference. Even here, however, the daily price is a fact that can be determined by any competent market reporter and does not depend upon esoteric information.

At the beginning of the war in Europe both the *Journal* and the *Press* suspended regular quotations. The reasons, perhaps, have not been fully understood. As a matter of fact there was no general market for copper, so no general quotation was possible. The conditions were closely analogous to those in the security market when the New York Stock Exchange closed. That was a war measure designed to prevent ruinous selling. Suspension of copper quotations was with the same object in view. No one doubts that with European demand at first absent and later greatly reduced, with domestic demand below normal, and a large surplus impending because of the impetus of production, copper prices would have dropped to five cents or less per pound before the curtailment could have made itself felt. Stopping quotations forced the small producers to join the big companies in reducing production, but if this is held to be a hardship, let the miner ask himself how he would have liked to continue to ship under his contract and settle for the copper at five cents per pound. Stopping quotations was a war measure, and, we believe, a proper one, but in any event the responsibility does not rest with the technical press; there being no general market, general quotations could not be made.

Since suspension of the regular quotations we have printed each week such data as were available covering prices at which copper was being sold. Admitting that the market is artificial, these figures still have value.

We publish this week the first general summary covering actual settlements made in New York by the large companies since the latter part of August. These represent real transactions in considerable quantities, but even they can hardly be considered to indicate prices at which the market would absorb copper if bidding were open as usual. These do, however, represent *the price at which copper is being sold*. We are glad to add that English demand is proving better than anticipated; domestic consumption, while sub-normal, is improving; no new production is coming into the market; and copper producers are already beginning to plan for a greatly increased output when the war closes. With a little patience and continued exercise of the good sense which producers and dealers have shown since this trouble came on them, these trying times will be passed without disaster.

CYANIDE NOW AVAILABLE FROM GERMANY

Further steps are being taken at Washington to secure for American mines a supply of cyanide from Germany. We are especially glad to mention this active and intelligent work on the part of the State Department in this case, because mining men generally have felt that the attitude of the Department toward them and their troubles in Mexico has been none too sympathetic. However, in this instance, from the Secretary down, the Department has been graciousness itself and is proving extremely helpful.

As we noted last week, the American ambassador at Berlin had been informed that export of cyanide to Mexico and the United States would now be permitted. Through the courtesy of Mr. Charles Butters we are permitted to repeat the following dispatch, received Monday last from Mr. Robert Lansing, acting secretary of state:

Despatch from Berlin states that although American ambassador has been informed by certain exporters that Secretary of Interior had agreed to export of cyanide, dye stuffs, chemicals, and medicines on guarantee that they were for the United States only, ambassador is now informed by under Secretary of Foreign Affairs, shipments of goods of this kind will not be allowed in Holland ships but in American ships only. Ambassador suggests ships could take over cargo of cotton and copper consigned to Holland merchants and return with above commodities. If America wants dye stuffs, cyanide, and chemicals, American ships must be sent. Would appreciate your suggestions at conference to be held September 30 at 3 p.m. at State Department to consider means for sending American ships. Will your firm share in expense? Suggest you send representative to Washington for conference or authorize someone in Washington to represent you.

Mr. Butters arranged for Mr. G. W. Shepherd of his staff, and Mr. Thomas T. Read of ours, to attend the conference. At the conference, as noted in our market pages, arrangements were made for immediate shipment of cyanide from Amsterdam in American ships. While the exchange proposed involves difficulties, as noted elsewhere, Germany is showing every disposition to respond to the needs of American industry as far as circumstances will permit, and we have strong hopes that a way will be found to permit importation of the cyanide. For our own part, we shall be glad to coöperate to this end with all concerned.

LARGE VERSUS SMALL STAMPS

For some years the tendency in stamp-milling has been toward the use of heavier stamps, and while it has not come into extensive use in this country, the heavy Nissen stamp has found much favor in South Africa, and in Cornwall as well. On another page Mr. Algernon Del Mar describes the large steam stamps which have long been standard practice in crushing the native copper ore, and raises the question whether they may be used to advantage in stamp-milling gold ores. Some further discussion of this question, in which we hope our readers will join, will not be without interest.

In the first place, we must take it for granted that a stamp is an uneconomical crushing machine. The stamp is not intended, and should not be used, for crushing any ore except ore in which native metal is scattered through brittle rock. For that purpose it is the logical machine, reproducing on a large scale the method anyone would instinctively use to free a mass of metal from adhering rock; namely, the striking of blows which crack open the brittle gangue and leave the ductile metal free. No matter how superior their mechanical efficiency, crushers which work by trituration or pressure are not suited to this work, as has been proved by experiment in the Lake Superior district. The stamp is therefore the proper machine for the crushing of gold ore and metallic copper ore, and with this as a major premise the characteristics of different types of stamps may be critically considered. Natural impulses are often safe guides to follow. Anyone would naturally employ a large hammer to drive a large nail and a small hammer to drive a small nail. If the use of a large stamp, striking a heavy blow, for crushing ore which is fed to it in small pieces, and the use of lighter stamps when the feed is finer is critically considered it will be found to be logically sound. The problem is not so simple as this, however. The use of large steam stamps for crushing gold ore can not be put on simple efficiency basis with their use for metallic copper ore. For many years it was the custom in gold milling to catch as much gold as possible inside the mortar, and amalgamated plates and grooved liners were used for this purpose. The problem in stamping was not simply to crush the quartz, but to crush as much as possible without scouring the inside plates. Mr. T. A. Rickard, in his 'Stamp-Milling of Gold Ores,' has lucidly discussed the effect which this and other considerations in gold milling has had on the design of the mortar and the force and speed of the stamp blows. In copper milling, on the other hand, provision must be made for the large masses of native copper, which, if allowed to remain between the stamp and die, would uselessly con-

sume large quantities of energy in being pounded into flat masses and gradually broken into fragments which would pass the screen. This involves the use of a roomy mortar, with spaces into which this copper can find a retreat, which is the probable reason for the otherwise illogical use of a die smaller than the stamp shoe. The hydraulic discharge for allowing the copper to escape from the mortar box has greatly helped to solve this problem, and it may be that the mortar now employed on the steam stamps is too roomy to give the maximum efficiency of discharge. If any studies of this feature have been made they have not come to our attention.

As long as amalgamation was the *sine qua non* of stamp-milling of gold ores, the steam stamp had another disadvantage in that it is necessary to lubricate the steam piston and oil was constantly finding its way down the stamp stem into the pulp, a proceeding which the millman regarded with horror. Much of this can be prevented by care, however, and now that the catching of gold on the plates is not so important a consideration, so long as it is caught before the tailing escapes from the cyanide plant, the efficiency of the stamping operation is more of a consideration than it once was. It may therefore prove to be more economical to give stamp-mills, in gold practice, a coarser feed, and use a steam stamp to strike a harder blow. Unquestionably the stronger blow is the better for the coarser feed. The trouble with the steam stamp, however, is that the length of the stroke of the steam piston is necessarily irregular, depending upon the amount of ore on the die. Thus the steam escapes at the end of the stroke with only part of its energy utilized, thus producing poor steam efficiency. In order to overcome this, the steeple-compound stamp was devised by Mr. Bruno Nordberg. Even this only partly overcomes an inherent difficulty. More recently Mr. F. L. Bosson has brought about the use of a low-pressure steam turbine to utilize the exhaust steam from the stamps, mixing the flow with boiler steam if necessary. This gives a better net total of efficiency, but detailed figures showing the gain have not yet been made public. This arrangement has already become the standard practice of the Calumet & Hecla, Copper Range Consolidated, and other large Lake Superior companies, though only a few steam turbines have so far been installed. It is to be hoped that detailed studies of the mechanical efficiency of this combination may soon be made public, so that the managers of large gold mills may have the necessary data on which to base conclusions as to whether large steam stamps working in conjunction with steam turbines would yield them a better net efficiency than the present practice of using heavy gravity stamps.

If gold mill operators are prepared to abandon the use of the stamp as an amalgamating device, and will send the stamp-mill pulp directly to tube-mills, passing the tube-mill discharge over amalgamated plates before sending it to the cyanide plant, the question may be raised as to whether it is necessary to retain stamps for the preliminary crushing of the tube-mill feed. The verdict of experience seems to be that the tube-mill is an excellent crushing device to free gold from its adhering gangue, the impact of the pebbles furnishing a sufficiently heavy blow for the comparatively small particles with which the tube-mill is fed. The logic of the situation would then seem to be that the crushing of the tube-mill feed should be done by the most efficient machine or machines, regardless of their principle of crushing action. This scheme of milling is about to be put into practice in the new large mills of the Alaska Gold Mines, and publication of the results of operations there will be awaited with the keenest interest by mill operators everywhere.

THE HALL PROCESS

Smelting men have no more difficult problems to face than those involved in rendering harmless the fume from roasting and furnace stacks. Among the most interesting attempts at the solution of the problem is that made by Mr. Theodore J. Hoover and his associates who propose by means of the Hall process to reduce the sulphur to the elemental form by roasting sulphides in an atmosphere lean in oxygen. We published an outline of the process July 5, 1913, and have since printed several notes on the progress of the tests at Coram. This week, through the courtesy of Mr. H. F. Wierum, who is in charge of the experimental work, we present a full account of the present state of affairs. Mr. Wierum discussed the matter before the New York section of the Mining and Metallurgical Society last week, and this publication is with his consent and in accord with an arrangement made at the time the experimental work was undertaken. The paper is full of interest and we commend Mr. Wierum for both his frankness and his caution. Everyone of experience recognizes the difficulties that lie in the way of such pioneer work, but not everyone is willing to discuss his own difficulties so illuminatingly. Evidently the Hall process has elements that show distinct promise; but evidently, also, there is much that is still to be learned.

Anyone may speculate as to the reactions involved and we may perhaps be permitted to question whether the old one between H_2S and oxygen, whereby sulphur and water is formed, does not enter into the result. Another question that suggests itself is whether, in the oxidation on the lower hearths "with free admissions of air" in the later experiments, SO_2 was not produced in the ordinary way, to be later reduced on the upper hearths by reaction with hydrocarbons, substantially as in the Thiogen process. If either of these surmises are well founded, there are disheartening possibilities of litigation over patents. We hope that whatever may be the chemistry involved, neither actions nor reactions will lead into the courts. Close quantitative work on fundamentals is still needed in connection with several of these processes, but nothing will so clear the way as such delightfully lucid and honest statements as Mr. Wierum has given.

Steam Stamps From the Gold Miner's Point of View

By ALGERNON DEL MAR

While the facts here set forth may be familiar to millmen using steam stamps, to the gravity stamp millmen the huge plants on the shores of Lake Superior are a revelation. My first thoughts were of the application of these stamps to the milling of gold ores, but after studying many stamp-mills I came to the conclusion that while for the copper ores of the district the gravity stamp would be useless, for gold ores the steam stamp would be at a disadvantage. Each type of machine has its usefulness, limited by the many conditions inherent in the physical character of the ores and the conditions under which the operations of milling are conducted.

The Problem in Copper Milling

The problem at the copper mills is to extract the maximum amount of copper at a minimum expense from rock that contains copper entirely in the metallic form. The masses of copper which reach the mill are of any size up to that passing the bars of the rock-house grizzly, which, judging from the appearance of the feed at the stamps, are commonly 4 in. apart. It will at once be seen that an ordinary stamp could not handle masses of copper of such size, for there is no place in the mortar for it to rest, except under the stamps, where it would be pounded to bits; a process not at all desired, for while 80% at the most might be saved by pounding the copper into pieces, 100% of this coarse copper is saved by separating it from the rock as soon as possible and holding it near the stamp in as large pieces as possible. The comparison, then, is between a steam stamp taking a 4-in. product and reducing it to ⅝-in. mesh (with the rock-breaker work not charged to the mill account, for this is done at the 'rock-house' at the shaft), and two rock-breakers working say to 2-in. mesh followed by gravity stamp crushing to say 10 mesh with no masses of metal to be taken care of. The character and amount of the free copper in the Lake Superior ores determines the process following the stamps, just as in a gold mill the amount and character of the gold determines the after process, but with this difference: a pound of copper is worth but 14c., while a pound of gold is worth about 2000 times this amount.

Any comparisons that may be made between steam and gravity stamps must include the difference in wages. In the Lake Superior district men are paid about 60% of what the same class of labor earns in gold mills, and the cost of power, which is far below that obtained in gold mills, must also be considered. In the Lake Superior region power may be generated or bought for less than one cent per horse-power hour. It is also to be remembered that the smallest copper mill with one stamp, crushing say 600 tons per day, would be a large-sized gold mill; the largest mill, with 28 steam stamps crushing approximately 12,000 tons per day, is of greater capacity than any gold mill. To crush the same tonnage of gold ore would require from 1500 to 3000

NORDBERG STEEPLE-COMPOUND STAMP.

gravity stamps. I cannot justify my faith by figures, for exact comparisons are not possible under the circumstances, but I do believe that, leaving out the mass copper, the gravity stamp is more economical than the steam stamp, per ton of ore stamped, even in localities where steam must be the motive power. A typical mill, one of the best in the Lake Superior district, shows by indicator cards that 2.3 tons per horse-power day was the crushing capacity of the mill. The complete stamp head in this mill weighed 6650 lb. The lifting velocity was 9.6 ft. per second, and the falling velocity 23.1 ft. per second. At 108 drops per minute, in 24 hours this stamp crushed 605 tons through a ⅝ mesh screen. I do not believe there is a stamp in the district, so far as I could gather, even on the softest ore, that had a capacity of over three tons per stamp per horse-power day.

South African Practice

This may be compared with the gold mills in South Africa, which crush from 5 to 6 tons per horse-power day through a 9-mesh screen. The only reason I can find for this difference in capacity is that, while in the gravity stamp-mill but a small layer of ore is kept between the shoe and the die, and thus the full force of the blow of the stamp is utilized, in the steam stamp, capacity is sacrificed to safety. From 6 to 8 in. of ore is always kept on the die, and should this be lowered to 3 or 4 inches the vibration in the shaft or stem is so intensified that the piston rod is liable to break. To change a piston rod means about 16 hours work, during which time the 600 tons per day equipment of the whole mill is at a standstill, while in the gravity mills the operator is not so particular, for he only loses the capacity of 5 stamps for half an hour when a stem breaks. The greater capacity of the gravity stamp-mill is partly balanced by the comparatively greater outlay in first cost.

In mills where no regrinding is done, the process being to stamp, jig, and concentrate, the cost per ton is about 16c. Of course, that cannot be approached in a gravity mill on account of the cost of labor and power; but if 4c. per ton be allowed for concentrating, the cost for steam stamping is 12c. per ton. At the Goldfield Consolidated, the cost of stamping is 13.3c. per ton, at the Alaska Treadwell 13.8c., at the Black Oak in California 11.26c., and at the Liberty Bell 19c. These gravity mills are all of much less capacity than the copper mill cited. The screen mesh is much finer, as is likewise the size of the feed.

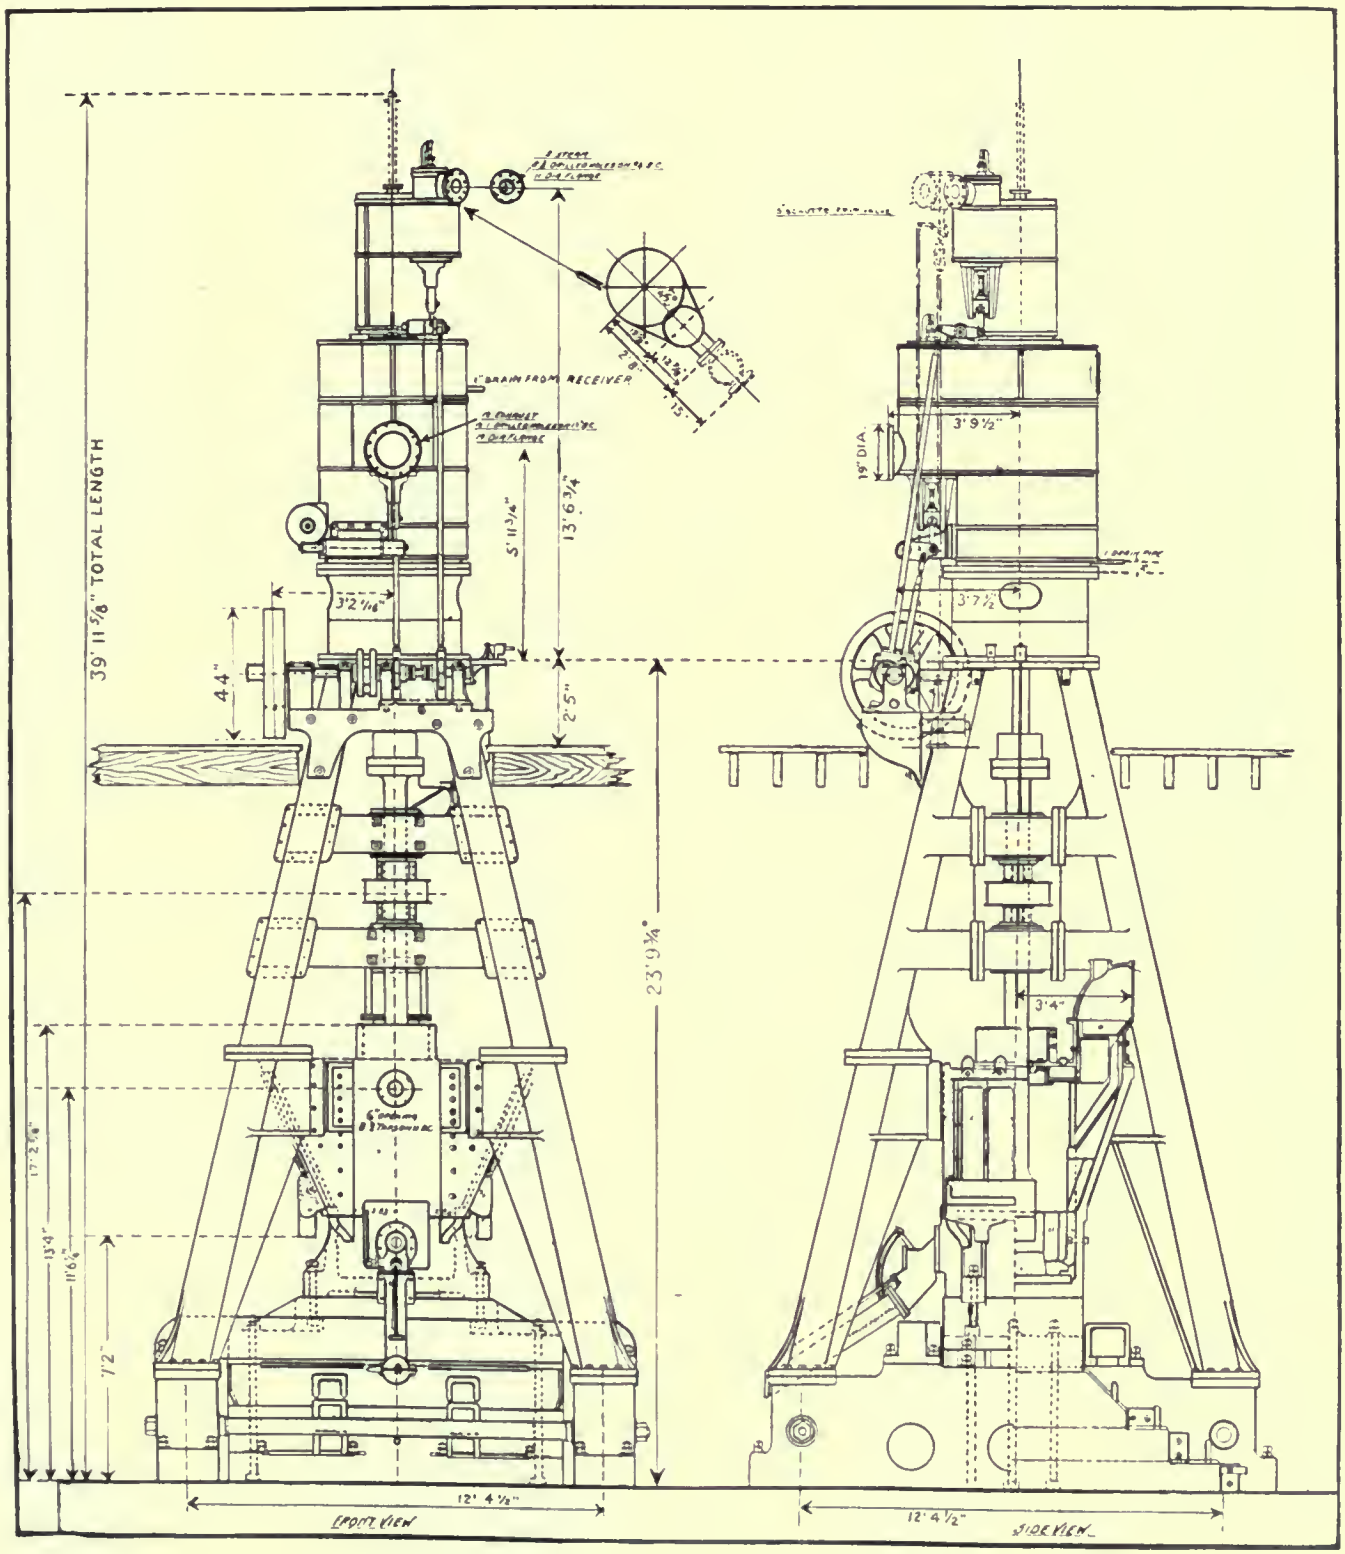
Steam stamps may be divided broadly into two types: the simple and the compound, the first type being represented by the Fraser & Chalmers simple and the Morris simple cushioned, and the latter by the Nordberg 'steeple-compound.' This refers to the steam portion of the stamp which may be superimposed upon a mortar with a circular opening, quadruple discharge opening, or with a two-side discharge, with four-post, two-post, or A frame. In the compound stamps there is economy in steam when they are run with a condenser, but when the exhaust steam is diverted to a low-pressure steam turbine the compound stamp does no better work than a simple one. In other words, better total efficiency is obtained by utilizing the low-pressure steam in a turbine than in the low-pressure cylinder of the stamp. Those not familiar with the steam stamp are at once struck with the fact that the rate at which the stamps drop, from 103 to 107 per minute, is regulated outside of the machine itself, the valve gear being operated by belt and pulley from a line shaft driven by power from an independent engine or motor.

One engineer usually takes care of two stamps, but three is possible by the use of an arrangement whereby the feeder man can at any time stop the stamp. This division of authority between engineer and feeder is by some operators thought to be a poor plan. A steam stamp is not fed automatically like a gravity stamp, but a man must be at each mortar to feed the ore as required, at the same time picking out all lumps of copper coming down the chute, which will amount to 6 to 8% of the total metal saved in the mill. Should anything happen requiring that the stamp be stopped, he pulls a cord which releases a catch and allows a 75-lb. weight to pull the steam-valve lever, shutting off the steam. Even if it were not possible to eliminate this 6% of copper from the mill system with a man at the feeder, the importance of not allowing a break of the stamp is so great that no mechanical feeder could be trusted. Some mills have a shaking feed, but a man is kept there just the same to pick out the copper and regulate the ore going to the stamp. The feed spout is always high enough above the mortar and inclined sufficiently so that all the feeder has to do is to regulate the feed with a bar bent like a poker. He does not shovel at all.

Drop and Stroke

The stamps drop with a stroke of from 24 to 25 in., with 6 to 8 in. of ore on the die, as already mentioned, and when the stamp has reached a safe limit on its downward stroke the bonnet on the shaft strikes a bell. It is therefore the business of the feederman to keep the stamp as near as possible to the point where the bell will ring. In a mill with, say, one steam stamp crushing 600 tons per day, there will be one engineer and one feeder on each shaft, and a repair crew of at least four men, which is about the same force as is required in a 100-stamp mill.

A new shoe for a steam stamp weighs from 780 to 800 lb., and when rejected weighs 380 to 400 lb. They are made of chilled cast iron, costing 3½c. per lb., and ¾c. is returned for the worn shoe, making the actual cost about 3c. per lb. This shoe will last from four to seven days, during which time it will have crushed 2000 to 4000 tons of ore at a cost per ton of ½ to ¼c. for iron. Various kinds of steel have been tried, but none proved equal to cast iron in cost. This shoe cost per ton cannot be approached in a gravity mill, for the



ALLIS-CHALMERS STEAM STAMP FOR MICHIGAN COPPER MINES.

freight alone is often more than the cost of cast iron delivered at the Lake Superior mills. Even should a steam stamp be transported to a gold mine, no means of comparison would be available. It is known that at the end of every four days or a week the shoe must be changed, taking at least half an hour, during which time the whole mill is idle, while in a stamp-mill only five stamps at a time are hung up every 120 to 150 days, and sometimes not even this, for the shoe may be changed on a clean-up day. The steam stamp must be hung up at least once a day to examine the wedge that holds the shoe to the shaft. This takes at least five minutes. This, in the case of the gravity stamp, is not necessary, so on the whole it may be said that the gravity stamp operates more of the time than a steam stamp. Account must be taken of the fact that the steam stamps do not run on Sundays, but repairs are made on this day if necessary.

A steam stamp die weighs about 800 lb. and is replaced when there is yet 500 lb. left; but this 300 lb. wear is distributed over seven months to a year, so that the cost of die material is a negligible quantity. The die is held down by a ring which in turn is held down by the staves or lining of the mortar, in which one section is bolted to the mortar, thus insuring that the die cannot be misplaced. The shoe is 24 by 16 in., rounded at the two ends, while the die is round and slightly less in diameter than the shoe. This is directly the reverse of gravity mill practice where the die is slightly larger than the shoe, but as the layer of ore on the die in the case of the steam stamp is thick enough to protect it from wear, the ring about the die takes any wear due to this cause. The depth of discharge or distance from top of the die to bottom of screen opening with a new die is 9 to 9½ in., increasing to 12 or 13 in. with a worn die. I measured one mortar in which the discharge was 16 inches.

Drawing Copper from the Mortar

About midway up the inside of one of the staves, or mortar lining, is a 5-in. diameter hole sloping downward at 45°. This is the opening in the mortar of the Krause discharge. A stream of water enters the 3-in. water-supply pipe, forming a hydraulic sorting column sufficiently strong to keep the ore in the mortar, but not strong enough to prevent lumps of copper from settling in the pipe. These are then drawn off at convenient times into a box. Some mortars have the opening at the top of the staves, while others have a hydraulic jig to answer the same purpose. From 10 to 15% of the total copper recovered is taken from this discharge, not entering the mill system at all. Thus the feeder and the mortar discharge together take out about 20% of the copper in the ore. The necessary object being, as mentioned, to take out the copper as soon as it is freed from the gangue, a 3/16-in. screen is placed after the stamp to take out the oversize passing the ⅝-in. battery screen. The oversize is jigged in a bull jig to take out the coarse copper, and the tailing is crushed by rolls or returned to the stamps. The 3/16-in. pulp passes to Woodbury classifiers, the product suitable for concentration being treated on Wilfley tables. This is the general scheme of treatment in those mills not requiring regrinding of the 3/16-in. mesh product, the elimination of waste taking place wherever most convenient and suitable. This is the right treatment where the 3/16-in. mesh tailing does not contain enough copper to pay the cost of regrinding and concentration, but in most of the mills where the sand tailing contains sufficient copper to pay the cost, regrinding and reconcentrating the product is the rule. While the cost of milling has increased to nearly double that in the mills where stamps and rolls alone are used, the extraction of copper has also increased. By careful comparative tests, extending over several years, C. H. Benedict has demonstrated that the pebble-mill is better adapted to this work than the Chilean mill.

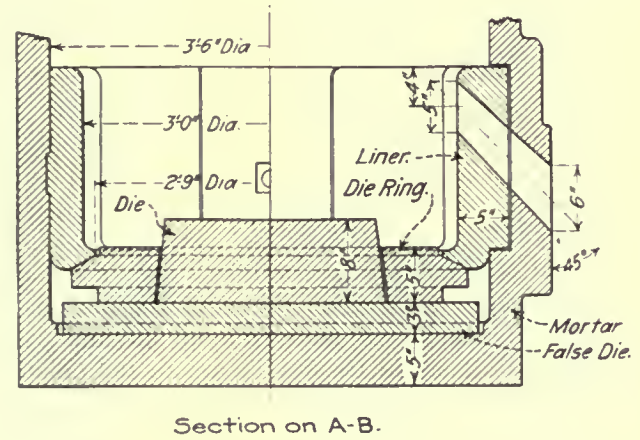
The system of concentration varies in different mills only in details, the plan everywhere being to remove a fairly clean copper product from each table and return the middlings to other tables suited for that class of work. The Wilfley table is the standard machine for concentrating coarse or fine ore. An interesting jig classifier is in use at the Quincy mill. This is the Shields and Theilman classifier, which is a series of small hydraulic counter-current jigs, taking but little floor space for its capacity. This machine was described in the *Mining and Scientific Press* of June 7, 1913.

On visiting the various mills I was struck at once with the readjustment due to the introduction of the Hardinge mill. Of regular tube-mills none are being installed, and only one was in use so far as I went. The visitor may well ask how Mr. Hardinge did it. One answer is that he was willing to undertake the building of mills for this work, while none of the tube-mill makers offered anything. While but one of the users told me he thought conical mills had any appreciable sizing action, and while few believe it any more efficient than a cylindrical tube-mill, and some thought there was no difference, yet all liked the mill because it is of handy size, its not occupying an excess of space per unit, and giving a product more even in composition than the Chilean mill, besides costing less for attendance and repairs. That the product was of a more even grade than that from the Chilean mills, I could see by comparing the material from each, on the tables. At one plant an 8-ft. Hardinge mill, a 4-ft. diam. 26 ft. long tube-mill and Chilean mill have run side by side, and while no economy in operation is claimed for the Hardinge over the tube-mills, yet they are preferred for other reasons, the Chileans going into the discard. It is only fair to the Chilean mill advocates to say that the mills tested are out of date in every respect, and to the advocates of ordinary tube-mills that the 4-ft. mill was too small in diameter for the work it had to do. The average feed to the regrinding plant has the following composition: 10 mesh, 17.1%; 20 mesh, 42.1%; 40 mesh, 34.8%; +60 mesh, 2.5%; and —60 mesh, 2.9%. A 6-ft. cylindrical tube-mill, I believe, would have shown better work for comparison.

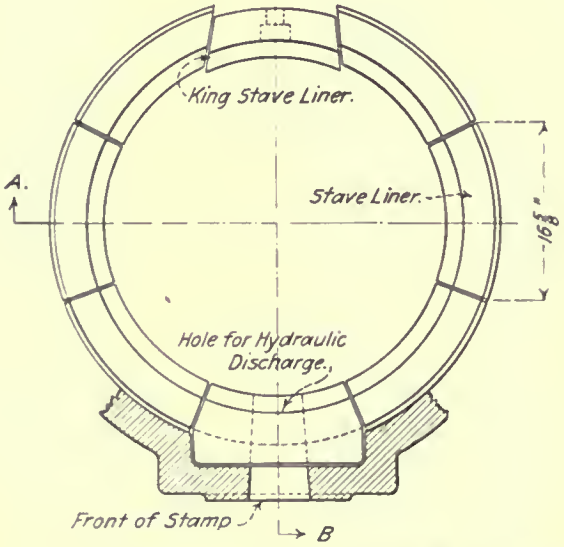
Spare Mills for Regrinding

The ratio of water to ore in the tube-mill feed varies from 3 or 4 to 1. This is much higher than that used in gold milling, but I was reliably informed at one plant, where the ratio was 3 to 1, that less water could not be used with benefit. I believe a careful investigation into this point will in future yield results. The new Calumet & Hecla regrinding mill plant, not yet completed, will contain 64 Hardinge mills, 8-ft. diam., 18-in. cylinder, and 320 Wilfley tables. The mills will be in two rows of 32 each, with an extra mill always ready repaired. These 64 mills are all run in boxes set on steel girders and not on concrete. There are two concrete foundations for spare mills. When a mill needs relining or other repairs, it will be lifted by a traveling

crane, taken to the spare mill, and the contents emptied direct into it, and will then be put on the other concrete foundation to be repaired. The crane will then lift the other mill, now filled and ready, and put it in the place of the one taken out, the whole operation not requiring more than half an hour.



Section on A-B.



DIE, RING, AND STAVE LINERS; ALLIS-CHALMERS STAMP AT WINONA, MICHIGAN.

These mills are all silex lined and run by 40-hp. motors at 475 r.p.m. They are driven by Westinghouse motors geared direct from the shaft. It is claimed that a saving of from 10 to 15% is made over those run by belt or intermediate plain geared shafts. Generally in the district the pebbles are fed at the discharge end. A boy takes care of three mills, throwing the pebbles in as far as practicable. No better way has yet been devised of feeding the pebbles, but there is no reason why the pebbles could not be fed in the feed end, especially where the scoop feed launder is dispensed with and the ore fed into the cone through a pipe. The objection to feeding pebbles with the ore in the scoop feed is that the scoop presses the pebbles in the feed box, which in time breaks or spreads the box out of shape.

That neither Chilean nor tube-mills are ideal regrinders for this copper ore is evidenced by the fact that but 50% of the copper is recovered from the tube-mill product and less than this from the Chilean. One reason for this poor extraction is that the grinding action in both these mills has a tendency to flatten the copper particles into thin sheets which are easily floated off on the concentrators. There is a good field for a machine that will regrind 3/16-in. mesh material to a slime at a small expense, and in such a way that the copper particles are granular or in some shape not easily floated. Such a machine has been tried, namely, the Lovett grinder. The machine may be compared to a pan without sides, in which the die has a circular motion and the muller a horizontal motion back and forth over the revolving disc. The result of these two motions is that the copper is rolled up in little balls or spirals. With this machine there is a saving of 20% over that made by tube-mills, but the power and wear costs are high and the output per machine is small. I have no doubt that this saving could be increased by passing the finished product through rolls with a grip sufficient to flatten out some of the spirals, for there is a tendency of some of them to go into the tailing.

The following interesting experiments with two different sized Hardinge mills will serve to show the requirements of regrinding. It will be seen that sliming is no objection. In fact, some operators would not object to 80% through 200 mesh, so, while the pulp going to the conical mills is somewhat coarser than in a gold mill, the resultant product is not much different. The figures were given to me by R. R. Seeber, of the Winona Copper Company:

1. Hardinge mill, 6-ft. diam., 5-ft. cylinder, 30.5 r.p.m.; 8140 lb. pebbles, plus feed; run by G. E. induction motor, 3 phase, 60 cycle, 2200 volts, 9.5 amp., 850 r.p.m., 35 hp.; G. E. starting compensator, type NR 1628, form a5. From rest this mill required 52 amp., attaining full speed at 9.5 amp. in 6 seconds. The mill feed dry weight was 1.75 tons per hour, with 30.3 average kilowatt. The screen tests were as follows:

Mesh	10	20	40	60	100	200	200
Feed	66	17	7	5	2	2	1
Product	..	..	..	6	17	26	51

2. Hardinge conical tube-mill, 8-ft. diam., 30-in. cylinder, 26.3 r.p.m.; 11,000 lb. pebbles plus feed. Motor, Allis-Chalmers induction motor, 3 phase, 60 cycle, 2300 volts, 11.5 amp., 850 r.p.m.; Westinghouse 'Autostarter,' type 184B, style No. 31239a. From rest this mill required 63 amp., attaining maximum speed in 6 seconds. The mill feed dry weight was 2.53 tons per hour; average kilowatt, 42.2. The screen analysis was as follows:

Mesh	10	20	40	60	100	200	200
Feed	35	18	7	8	13	11	8
Product	..	1	3	9	21	33	33

For those interested in efficiency tests, I find that by the "reduction by area" method the efficiency of the 6-ft. mill compared to the 8-ft. mill is as 104 to 90. Mr. Seeber worked the comparison out by Stadler's method based on Kick's law, finding the ratio to be 13.27 to 8.63. There can be no doubt that the first ratio is more nearly correct than the second, for it is most improbable that the 6-ft. mill could be half again as efficient as the 8-ft. mill.

Experimental Development of the Hall Process

By H. F. WIERUM

The Hall process aims to eliminate sulphur from sulphide ores or matte without allowing any SO_2 to escape, and to recover the sulphur thus eliminated. The purpose of this article is to describe what measure of success has so far been attained. For some four or five years prior to 1914, my problem had been to make as much and as rich an SO_2 gas as possible, at the Tennessee Copper Co. works, which I had charge of, in order to make sulphuric acid. It was quite a wrench to my feelings, therefore, to be required to turn around and try to make a gas as poor as possible in SO_2. But the interest in the process soon became fascinating, and it was a hardship for me to have to stop the experimental work at Balaklala, in California, just as the A B Cs of the process were being well developed.

Early Work in Europe and Brooklyn

William A. Hall, the original inventor of this process, tried out his first ideas, I believe, at a little place near Paris called Levallois. He used a small brick-lined circular furnace about 18 in. diameter, with a removable tile top, into which he introduced pyrite, and which he heated by means of very low-grade producer gas carrying but 130 B.t.u. per cubic foot. The results obtained in this furnace were interesting only as an impetus to further investigations. Without any regard as to how many pounds of pyrite was treated, or how many cubic feet of gas was used, the tests simply resulted in a fairly complete desulphurization of the pyrite without any detectable SO_2 in the fumes, which consisted of a mass of white or yellowish white sulphur vapor, as they appeared to the eye, when leaving the discharge pipe of this furnace. Steam in small but entirely unmeasured quantities was introduced at the same time as the gas, through jets placed between the gas burners on the furnace. To say the least, it was a startling sight to see pyrite introduced into a glowing red-hot furnace and then to be able to breathe the discharged fumes without any of the familiar choking odor of SO_2 being detected.

These experiments were repeated on a similar furnace, but with different gas, in London, and later in Brooklyn. The gas used both in London and Brooklyn was the ordinary city gas of from 500 to 600 B.t.u. per cubic foot. The results were the same. It should be noted that in both these preliminary experiments air was carefully excluded from this furnace, except such air as was blown into the gas burners themselves, in quantities just sufficient to completely burn the amount of gas introduced. Lest some of you question in your minds whether air was really excluded, let me explain that the manner in which it was excluded was a very efficient one, namely, the maintaining of a rather heavy back pressure in the furnace so that when any opening in the furnace was made the flame and sulphur fume would shoot out from such an opening instead of the air being drawn in.

Of course, it has long been known that about one-half of the sulphur in FeS_2 can be distilled from it by a mere application of heat; about 1300°F. is required to start the distillation effectively. The remaining one-half, however, it has always been contended, cannot be dislodged from its connection with the iron or any other base by simple heat. With these experiments just recorded before him, Mr. Hall drew up his first patent papers and attempted his first theory in the premises; and of all the many prominent and experienced engineers who witnessed these first little tests, I do not know of one who was not strongly impressed by what he saw. They were puzzled, however, and many a pencil was set busy trying to figure out possible chemical reactions that had apparently heretofore escaped the scientific world. Now it is entirely possible to write a reaction which will account for what the eye saw during these short tests, but whether such a reaction actually takes place *I am not prepared to say*, and every metallurgist is perfectly free to form his own opinions as to the feasibility or otherwise of such combinations as the following.

Reactions Involved

Let us assume, first, that about one atom of sulphur has been distilled by mere heat from FeS_2, leaving a sub-sulphide of iron which can be roughly designated as FeS. Now comes the first chemical reaction:

$$6FeS + 6H_2O = 6FeO + 6H_2S$$

Many will doubt the ability of any heat obtainable in a roasting furnace to break up water in any such manner as this. Nevertheless, here was this little furnace, with an air-supply insufficient even to burn completely the gaseous fuel used, turning FeS_2 into Fe_3O_4, with only the oxygen of water, available as a stable equivalent for the S, in combination with Fe. Red-hot iron decomposes water, why not red-hot FeS, or Fe_6S_7, or carbon, or red-hot anything that it is not known positively will not do it? Such were the questions the experimenters had to ask themselves. So we go bravely on, and accuse the little furnace of decomposing enough water to satisfy the second reaction of the cycle:

$$6FeO + 3O = 3Fe_2O_3$$

Following this comes the third chemical reaction, which I think is quite feasible under suitable conditions, especially provided the two foregoing reactions can be brought about:

$$3Fe_2O_3 + 6H_2S + 5O = 2Fe_3O_4 + 6H_2O - 6S$$

It seems fruitless, however, to discuss whether or not any such cycle of reactions actually occurs. I simply wish to emphasize one fact, that in the little furnace described above, FeS_2 carrying some 48% of sulphur was freed from its sulphur down to about 5% by a treatment with producer gas at a temperature of about 800°C., introduced with insufficient air to burn completely this producer gas, and with some steam present, at the same time maintaining such a strong back pressure that no suction whatever existed in the furnace and no outside air could possibly have been drawn in.

Larger Furnace Tests

The next step in investigating what happened was the construction of a slightly larger furnace, mechanically rabbled, but of the same general design as these little pot furnaces just described. The only step accomplished by this increase in size and efficiency of the furnace was the obtaining of a record of how long the ore was under treatment, and in keeping accurate and continuous data concerning the amount of SO_2 contained in the fumes. The result of the official tests, which were conducted under the auspices of two of our most respected and experienced chemists and metallurgists, was that the SO_2 was always below 0.10%, that the sulphur in the calcine was down to 3% or under, and that the weight of ore treated per square foot of hearth area was approximately the same as the weight treated in the regular McDougall furnace per square foot of hearth area per 24 hours.

One other point was tested in this second furnace. Some chemically pure sulphide of iron was bought, corresponding to the formula of FeS. This contained no feeble atom, or unstable atom of S, and yet this material was decomposed under exactly the same conditions as the pyrite, with practically identical results. In the later trials, this experience with monosulphide of iron and also with some matte (which roughly answers the formula of monosulphide of iron) has always puzzled me, and still continues to puzzle me.

When the tests had reached this point, I was called upon to carry out certain experiments that had been arranged for by the gentlemen controlling the rights to this process, at a large smelter in California which had been closed down for some time, and I had only rather meagre data to go on in equipping a unit to handle 25 or 30 tons of ore per day when the largest scale upon which this process had been tried had been about 25 or 30 lb. per day. I was unfortunately very much pressed for time under existing conditions, and had to attempt the impossible in getting a gas plant built, furnace equipped, and some tests completed in three months' time. The result of this haste was that I was unable to try out the producer gas plant, or to change it to a generator plant, in the specified time. So, to make a long story short, it was found necessary to extend the time to be devoted to these tests, and when this was arranged the gas plant was put in excellent shape with washers and a fairly large gas holder, so that when we started up again, about January last, we had good clean gas to deal with. During this second construction period, however, we equipped a second McDougall furnace with oil burners. Strangely enough, the totally unsatisfactory tests made with oil burners in Brooklyn led the staff to believe that crude oil was not a suitable fuel for this purpose, and therefore the equipment of a furnace with oil burners was simply undertaken as a side issue. However, this furnace later proved more valuable in developing the process than did the gas-fired furnace.

About January 1, 1914, the gas-fired furnace was started, but unfortunately it was impossible to keep it operating during the month of January for 24 hours at a stretch, not because of any difficulty with the plant or process, but purely and simply because Shasta county, California, was then enjoying unusually bad weather. Storm after storm interrupted the electric power-supply of the plant, and no sooner would the furnace be heated and filled with ore and the sulphur coming off nicely through the flues, than the power would go off, the blowers and motors all stop, and immense volumes of SO_2 begin to pour from the stack. These interruptions occurred on an average of twice a day for the first two weeks of January, and nearly once a day for the last two weeks, so that I became quite discouraged over the possibility of obtaining any reliable results in time. Meantime, however, the oil-fired furnace was made ready, and one occasion when the shut-down was more prolonged than usual was seized upon to stop the gas furnace and start the oil one, which was far less dependent upon electric power. During the early part of February, steam power sufficient for most of the requirements having been hastily provided, the oil-fired furnace was operated. Although still subjected to many interruptions, these were gradually eliminated, and the weather became better, so that after a week or so real progress began to be made.

Ore Used in Tests

The ore provided for treatment was crushed to ½ in., and as this ore was not in the slightest degree friable, being very dense, ½-in. pieces were found to be distinctly too big. Therefore, a system of screen analysis was adopted on the calcine, and while from day to day the sulphur elimination in the material which passed the 10-mesh screen seemed to improve, nevertheless it was found extremely difficult, if not quite impossible, to roast the ore down to the 5% point aimed at under the conditions which we first imposed upon the furnace.

Careful analyses were made of the atmosphere existing on each hearth of this 18-ft. McDougall furnace which was employed and in the flue leading away from it, and for the first two weeks tests were conducted in an atmosphere which contained about 1% or less of free oxygen and a rather generous percentage of CO; in other words, a highly reducing atmosphere throughout. It was under these conditions that the experiments failed to produce a better calcine than about 11 or 12% sul-

phur in the 10-mesh material. The larger pieces of ore as they came from the furnace were barely singed, and an analysis of these showed about 26% sulphur; the original ore having contained roughly 40%. But I should record that in all this period hardly a trace of SO_2 existed in the escaping gases.

Time was again pressing, due to certain business arrangements which had been made, and I found it impossible to try all the variations which I would like to have tried under completely reducing conditions in the furnace. I therefore began slowly to allow a little oxidation to occur on the lower two hearths of the furnace, and in doing this finally hit upon a set of conditions which seemed economically very important to the industry and to the problem of fume destruction. Let me state briefly in figures what the best results were, maintained constantly for several days, and each will be able to judge for himself whether or not there is reason to hope for important commercial developments in this process. For about a week the ore was fed at the rate of 24 tons in 24 hours. During this period the sulphur remaining in the 10-mesh calcine averaged 5½%. The sulphur remaining in the total sample of ½-in. material, coarse and fine together, averaged about 8.8 per cent.

Oil Consumption

The oil consumption was about 22 gal. of oil per ton of ore. The oil used was a very cheap material carrying 25% of asphalt and of about 23°B. gravity. The SO_2 in the fume escaping from the furnace for the entire period was a trifle over 0.3%. The labor required is practically the same amount as is required for ordinary McDougall roasting, and, of course, the more furnaces and the larger tonnage treated, the lower the labor cost per ton, inasmuch as it takes just as many men to tend and feed one furnace as it does four. Note that although the figures just given are the averages of almost hundreds of samples of gas and calcine, the entire period showed improvement toward the end and afforded an opportunity of studying what changes in the furnace itself would conduce to still more favorable results. Toward the end of this period, when the staff became more familiar with the behavior of the furnace under this controlled atmospheric condition, the best results, maintained for 24 or 48 hours, may be stated briefly as: oil consumption, 16 to 17 gal. per ton of ore; 10-mesh calcine, 5.3% of sulphur (although for two or three days the calcine ran between 2.8 and 3.6% sulphur); and SO_2 frequently as low as 0.06%. It is necessary to bear in mind the fact that these tests were all made in an existing furnace with all the mechanical arrangements, such as the speed, angle of the rabble blades, depth of the bed of ore carried, and the length of time in the furnace, adjusted for regular conventional pyrite roasting operations, and it is not surprising that some of these conditions demanded alteration in order to obtain the best results from quite a different operation. Such alterations were beyond the bounds of possibility in the short time available, and metallurgical common sense must therefore come to the rescue in predetermining roughly what effect certain changes will have. I wish to avoid too many statements of my own private opinion, but will give for what it is worth the conclusion that my study of the matter has brought about in my own mind as to the possibilities. I think that with 10-mesh ore and arrangements for more frequent rabbling, and suitable means for keeping the ore in certain portions of the furnace for a greater length of time than the present conventional practice provides, the following results can without difficulty be maintained as a regular thing: In an 18-ft. McDougall furnace I believe it possible to treat 40 tons of 10-mesh ore daily with a consumption of 500 gal. of oil, roasting it down to 5% sulphur, and controlling the escaping fumes so that they will never exceed 0.3% SO_2, and would probably average 0.15% or less. I trust that no one will get the idea that this last set of results which I have given have actually been accomplished; they are simply my opinion, based upon the experience that I have had, of what can be attained in time.

Now for a word or two about the chemical reactions. In the upper portion of the furnace, about one-half of the sulphur is distilled by mere heat. The lowest portion of the furnace, say one-third of the hearth area, is devoted to the oxidation of the iron, copper, and remaining sulphur by a free admission of air. In the middle third of the furnace portion, a strongly reducing atmosphere and rather high temperature, say 1500°F., are maintained. It is in this central portion of the furnace where the SO_2 formed below is broken up and reduced to elementary sulphur. It is an undeniable fact that some H_2S is formed in the upper regions, and it is equally undeniable that H_2S will react upon SO_2 under certain conditions, forming water and sulphur; but I have not been able to prove that the $H_2S + SO_2$ reaction is the controlling feature in the reduction of SO_2. When a too strong reducing atmosphere is permitted in the presence of liberated elementary sulphur and steam, certain undetermined organic sulphides are formed which seriously interfere with the production of sulphur. There seem to be two ways of avoiding this interference. First, the avoiding of too great an excess of fuel. Second, a quick drop in the temperature at the point where these conditions of excess oil vapors and free sulphur exist. Naturally, the former is the more economical way out, but both have been proved feasible.

Failure of Washer

In attempting to save the sulphur, a Feld washing machine was provided to wash the elementary sulphur from the gases, and for the first two or three hours after a free discharge of elementary sulphur had been secured from the furnace it looked very much as if this machine would take care of the sulphur most effectively. But four or five hours continuous running led up to serious trouble. The thick, creamy-looking emulsion that came from the washer was led into tanks provided with sand

filter-bottoms, and the filtrate from these tanks was beautifully clear and free from any sulphur; but presently a disturbance in the draft condition of the furnace appeared, and investigation proved it to be caused by a complete clogging of all the gas passages in the washer. Fortunately, facilities had been provided for by-passing the gases around the washer and allowing them to escape into the air from the stack. This was done, and upon opening the washer it was found to be completely clogged up with yellow and gray sulphur, so sticky and plastic that neither a stream of water under high pressure nor a jet of steam would remove it from the interior surfaces. Anyone familiar with the construction of a Feld washer will appreciate how impossible it was to clean the inaccessible spaces between the lead cones in this washer when once stuck up with this plastic mixture, and after this first experience it was only possible to use the washer for an hour or so at a time, and then very ineffectively. Most of the time during the experimental work in California the gases, which consisted of a thick, heavy yellow cloud of sulphur, were discharged through a fan to the stack and thence out into the atmosphere. Innocuous, it is true, but tantalizingly uneconomical.

Electric Precipitation of Sulphur

To the small furnace in Brooklyn we had previously, in the course of our tests there, attached a treater of the Cottrell precipitation type, and found that this electrolytic discharge was completely efficient in collecting the sulphur. Unfortunately, business arrangements could not be made in the time at our disposal to install a Cottrell precipitation plant in connection with the McDougall trials in California, so that until very recently I have been unable to say positively how the liberated sulphur can be recovered. Though I and most of my associates are reasonably sure that the Cottrell method will prove both economical and efficient, it goes without saying that much experimental work would be required before satisfactory plant details could be worked out.

However, while looking into certain proposals in Hungary about two months ago, I happened upon a government sulphur factory which had been in operation for many years. This was at a little place called Zalatna, in Transylvania, and I was greatly pleased to see with what facility the elementary sulphur was washed out of the gases in simple and inexpensive wooden towers which contained many baffle-boards over which a saturated solution of chloride of calcium was flowing. The consumption of chloride of calcium was almost *nil*, the emulsion coming from the foot of the towers was led into a series of tanks where the sulphur settled out quite completely without any filtering, and the clarified chloride of calcium solution was again pumped to the top of the towers. The settled sulphur is then heated in closed drums under a light steam pressure, the molten sulphur is drawn off at the bottom, and the $CaCl_2$ recovered is drawn off at the top. Naturally this suggestion seems the cheapest way of solving the problem, and I had three towers half constructed in London, with the object of duplicating the performance which I witnessed in Hungary, when the war broke out and all business was stopped. Arrangements had about been perfected whereby I was to construct in the northern part of Norway a plant similar to the one with which I experimented in California, but the war has also put a complete stop to that, so that the Hall process has had ill luck again.

I have here described quite frankly practically everything that there is to be told concerning experimental work with the Hall process thus far. I have found a feeling prevailing among many people, who have heard of this process, which I very much regret. This is a feeling that claims have been made which are too broad and complete really to deserve credence, and I am glad of an opportunity to state that no further claims are being made than can be deduced from the results here presented. I realize that there are many points still to be perfected, but I feel strongly that the Hall process, now in process of development, constitutes an important improvement on methods of handling gases which will ultimately play a big part in abating the fume nuisance and in supplying the market with sulphur.

Efficiency of the Burro

By WM. A. BURR

*The burro fills a place in the mining and metallurgical world that no machine can entirely fill. He can carry steadily on his back, loads ranging from 125 to 250 lb. He can forage for himself if necessary. He can make his own trails. He can ascend the loftiest peaks with his load and climb to places with comparative ease that a man can only reach with difficulty. His cost ranges from $4 on the southern border of the United States to $20 in our own vicinity, for average animals. He is almost as easy to raise as a chicken, and is broken under the pack in one day. His rate of travel loaded, for inferior animals is seven miles per day, and for animals in good shape fourteen miles; the average may be taken as eleven miles.

In packing from mine to mill a distance of one-half mile, a burro could make ten trips a day if properly handled, and consequently carry three-fourths of a ton of ore at a cost of 45c. per ton, providing not less than a dozen burros are working together. On a one-mile haul three burros could deliver one ton of ore per day and thirty burros could keep five 1000-lb. stamps dropping with a transportation cost of 75c. per ton; while with a three-mile haul 150 burros could keep a 10-stamp mill supplied with ore at a cost of $1.50 per ton or less. And I recommend to you the re-adoption of these valuable little animals in the solution of your difficulties in transporting ores in mountainous places off the railroad where roads are not passable for wheeled vehicles.

*From an address delivered before the Northern California and Southern Oregon Mining Congress.

OFFICE AND LIVING QUARTERS OF CREW.

Building a Placer Mining Dredge With Electric Power Plant in Portugal

By H. G. PEAKE

Portugal has, for a great many years, produced small quantities of placer tin, but only within the past three years has any deposit been proved which would warrant the erection of a plant of any magnitude. During the summer of 1912 certain areas in the northeastern part of the country were drilled and on the Gaia river near the town of Belmonte, district of Beira Baixa, sufficient ground suitable for dredging was proved to warrant exploitation. It was thereupon decided by the owners to build a suitable power plant and a dredge.

Owing to the slight snowfall, even in the highest altitudes of this district, the summer flow of all of the streams is small, so it was decided to erect a steam plant for generating electric power at the railway station of Belmonte. This station is about two and one-half miles from the town of Belmonte, on one side of a low divide, and the dredge site is on the opposite side about five and one-half miles from the town. This made the transmission line about eight miles long. The power station is equipped with a Babcock & Wilcox water-tube boiler, with superheater. A Ratteau high-pressure steam turbine is direct connected to the dynamo. This dynamo has 250-kw. capacity at 80% power factor, runs 3600 revolutions per minute, current 60-cycle, 3-phase, voltage 6600. The exciter is mounted on the generator shaft. A jet condenser is placed directly under the turbine. All water from the condenser delivers into a hot well. From here it flows by gravity to a sump and is pumped to the cooling tower by a 4-in. centrifugal pump. This cooling tower is erected over a large concrete basin and the water flows by gravity to the condenser tank from this basin. The water supply for the plant is taken from a small stream about 2800 ft. distant.

Transformers are situated at the dredge, stepping down from 6600 volts to 440. All of the motors are operated at this voltage. The transmission line follows the government road. Poles and cross-arms are of wood and the transmission line of hard drawn copper. The technical work and the construction of this plant was under the direction of J. S. Soares, formerly of Marysville, California.

The ground to be dredged is alluvial, averaging 17 ft. deep and is quite level. The climate is such that dredging can be carried on all the year round. Practically all of the land is under cultivation, so no timber has to be cleared away, and the only boulders found are on the surface along the river banks, where they have been placed to prevent the water cutting away the soil.

It was decided to build a 4-cu. ft. close-connected dredge with steel pontoon. This equipment was built by Fraser & Chalmers of London, and after considerable delay in dealing with the customs authorities of Portugal the material was shipped to Lisbon. From Lisbon all material was transported by rail to Belmonte station and from the station to the site where it was to be erected, the material was transported by auto truck and ox carts. During the delay on account of customs, living quarters were built, work was carried on at the power

GENERAL VIEW OF VALLEY WITH FLUME TO DREDGE PIT.

PLACING THE SWINGING WINCH ABOARD.

plant, a pit was prepared for the dredge, and a temporary machine shop was put up. On November 17, 1913, the first bottom plate was laid and the dredge was placed in commission on April 19, 1914. The crew employed on this construction work was made up of eight American dredge men from the Oroville district, three Englishmen from Fraser & Chalmers' shops, four Portuguese riveting crews from Lisbon, and about 20 native Portuguese laborers.

The dredge was designed to dig 26 ft. below the water line. The general arrangement is similar to California practice, except as to sluices and stacker. There are

eight sluices, four on either side, running fore and aft, each sluice is 90 ft. long, 43 ft. on board the dredge, and 47 ft. projecting beyond the stern. These sluices are arranged with head gates so that one on each side may be cleaned up while the others are in operation. The conveyor is horizontal, mounted on a stationary steel frame, the carrying belt is 10 ft. 6 in. above the deck, and the discharge is at a point about 30 ft. beyond the stern.

This design was adopted with the view of leaving the dredged ground as nearly level as possible so that it could again be used for agricultural purposes. It was possible to adopt this type of dredge on account of the small percentage of heavy wash in this particular alluvial deposit. Probably not more than 20% of the material will be rejected by a screen having one-half inch diameter perforations.

The sluices are fitted with riffles and the concentrate is shoveled to the head of each sluice and into a hopper feeding a worm-type conveyor. This conveyor delivers into a second screen, where the material is sized for jigging. The jigs are directly under the main revolving screen, and are driven by a separate motor. So far as I know, this jigging plant is the first attempt to handle the concentrate in this manner on a placer tin dredge. The usual custom has been to wash and clean the concentrate in the sluices to a certain extent, then transfer to a plant on shore and finish the cleaning. In one plant, visited in Cornwall, this process made it necessary to stop the dredge for about two hours each day while the concentrate was being transferred to wagons. The shore station in this instance had one small jig which removed the heaviest particles of cassiterite. The fine material was further treated by hand. About 30 to 40 tons per day was transported from the dredge to the shore station.

With the jigging plant, as installed on the dredge in Portugal, it is anticipated that practically a clean concentrate will be made. In any event, the bulk of material to be taken ashore will be so reduced that it will not be necessary to shut the dredge down in order to transfer it. The fine concentrate from the jigs will, in this case, consist of material averaging approximately 70% titanic iron and 30% cassiterite. To remove this large percentage of iron, a Weatherill magnetic separator has been installed at the power station. The concentrate is dried on a large steel plate, placed over a horizontal flue, extending from the boiler to the smoke-stack. It is then screened, nothing over $\frac{1}{16}$-in. diameter going to the separator. The oversize from the screen will undoubtedly contain some particles which carry considerable granite. It remains to be found by operation what percentage of this material there will be. If very much of it is found, it is planned to install a small set of crushing rolls to free the cassiterite. It will then be rewashed, dried, and run through the magnetic separator.

THE COMPLETED DREDGE AT WORK.

MINERAL PRODUCTION of Illinois in 1913 was valued at $131,825,221, of which coal mines contributed $70,313,605; petroleum, $30,971,910; and brickyards, tile works, and potteries, $15,195,874. In 1912 the value of the total mineral production was $123,068,867, including $70,294,338 for coal, $24,332,605 for petroleum, and $15,210,990 for clay products. Portland cement was worth $4,784,696, an increase of $1,340,611. Manufacture of pig iron and coke, the raw materials for which are imported from Lake Superior districts and West Virginia, amounts to about $55,000,000, the Chicago district being one of the most important in America.

IMPORTS of crude and manufactured mineral products into the United States in 1913 was $270,000,000, of which 74% was raw material.

Method of Mining at Republic Mine, Republic, Michigan

By R. B. WALLACE

*To illustrate the method of mining used at this hard-ore mine we will take as an example a body of ore averaging 20 ft. wide and 80 ft. long and extending several hundred feet in height. These 'lenses,' if we may call them such, do not always stand vertical, but may be inclined as much as 20 or 30 degrees.

The first step in extracting the ore is to drive a 7 by 7-ft. drift through the entire length of the orebody. The ore is then cut out the full size of the orebody to a height of 15 ft. and the stull over the tramway put in place. Breaking is then commenced and the ladder-

FIG. 1.

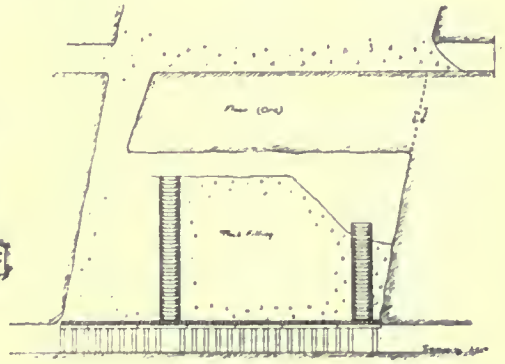


FIG. 2.

way mills are built up as is shown in Fig. 1. Fig. 2 is a longitudinal section through the stope showing the openings for drawing off the ore left every 25 ft. in the side of the timbered tramway. Only enough ore is drawn off to enable the miner to set up his machine.

In some places where the orebody is of greater length, this method has been modified, since the timbered tramways have to be renewed before the stope is finished. A drift is run parallel to the orebody about 10 ft. back in the foot-wall, and from this drift cross-cuts are made every 25 ft. into the stope; through these the ore is drawn off and access is obtained to the ladderway mills. A cross-section through one of these cross-cuts is shown in Fig. 3.

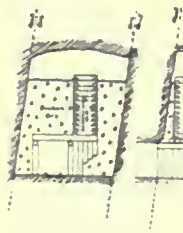

FIG. 3.

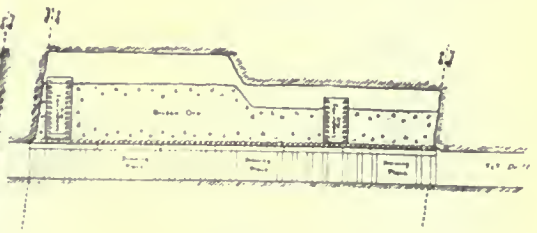

FIG. 4.

In the old workings are some floors which are being taken out. The process is slow, as the open stope below has to be filled with waste rock. There is an abundance of this and sometimes it is intermixed with enough ore from caved pillars and floors to pay for separating and handling the rock. Fig. 4 is a longitudinal section of a stope which is almost filled with waste rock preparatory to mining the floor. When the stope is filled to within 6 ft. of the back, breaking is commenced and the ore is thrown down the mills. More filling is leveled across the stope and the floor is thinned till finally it is broken through.

*From advance proofs of a paper read before the Marquette meeting of the Lake Superior Mining Institute.

Natural Gas Production

The production of natural gas in the United States in 1913 was the greatest in the history of the industry. The total yield is estimated by B. Hill, of the U. S. Geological Survey, at 581,898,239,000 cu. ft., valued at $87,846,677, an average price of 15.10c. per 1000 cu. ft., as compared with 562,203,452,000 cu. ft., valued at $84,563,957, an average of 15.04c., in 1912, the increase being 19,794,787,000 cu. ft. in quantity, and $3,282,720 in value. Of this total product, about 32% was utilized for domestic purposes, or 184,885,662,000 cu. ft., valued at $50,522,415, an average price of 27.33c. per 1000 cu. ft., and 68% was utilized for industrial purposes, or 397,012,577,000 cu. ft., valued at $37,324,262, an average of 9.4c. The industrial consumption includes gas used for both manufacturing and producing power.

West Virginia led with 245,453,985,000 cu. ft., valued at $34,164,850. Pennsylvania was second, with 118,860,260,000 cu. ft., valued at $21,695,845. On the other hand, Pennsylvania was the leading state in 1913 in quantity of natural gas consumed, with 177,463,230,000 cu. ft., valued at $28,709,565, and Ohio second with 128,204,722,000 cu. ft., valued at $27,055,824. The extraction of gasoline from natural gas, or casing-head gas, from oil wells in the United States has become an industry of some importance in the past three years. Returns received from producers of gasoline of this character indicate that the production in 1913 amounted to 24,060,817 gal., valued at $2,458,443, an average price of 10.22c. per gallon, as compared with a production of 12,081,179 gal., valued at $1,157,476, in 1912, and 7,425,839 gal., valued at $531,704, in 1911. In 1913 West Virginia produced 7,662,493 gal. of natural-gas gasoline, valued at $807,406; Oklahoma, 6,462,968 gal., valued at $577,944; Pennsylvania, 3,680,096 gal., valued at $405,186; California, 3,460,747 gal., valued at $376,227; and Ohio, 2,072,687 gal., valued at $212,404. The balance of the 1913 output was produced by Illinois, Colorado, New York, Kentucky, and Kansas.

NINETEEN MINING COMPANIES are operating in Honduras, Central America, but only three or four are actually producing. The Rosario mine in 1913 produced 76,128 tons of ore yielding 1,593,885 oz. silver and 11,193 oz. gold.

Weighing Minute Spheres of Gold and Silver

By J. I. BLAIR

In assaying ores or other substances for gold and silver it very often happens that the resulting 'button' or tiny bead of the metal that remains in the cupel is so small that it cannot be safely removed from the bone-ash cupel. For a long time in all such cases the result of the assay was given as a 'trace,' meaning that only a trace of gold or silver was found. But with the advent of better metallurgical processes for the treatment of the poorer ores it has become essential that the trace shall be a known quantity. Before, it meant anywhere from a few cents to fifty cents per ton of material treated. Since weighing these buttons was out of the question it became necessary to estimate their weight from their size. For this purpose a graduated scale was scratched on a piece of circular glass which could be inserted into the lower tube of a compound microscope. By this means the diameter of the bead may be obtained, and from this the volume of the metal and the weight of the button may be calculated. The instrument may be calibrated by using a piece of platinum wire of known diameter as a standard, or any other material of which the diameter is known.

To facilitate the work, tables have been prepared which make it possible to read direct the weight of the bead from its diameter and then the quantity of gold per ton of ore or material assayed. Such tables are easily prepared to fit each one's need.

In making up a table the following formula was used: The diameter in hundredths cubed, multiplied by the weight of a sphere of water 0.01 mm. in diameter, multiplied by the specific gravity of the metal. A sphere of water 0.01 mm. diam. weighs 0.000,000,523.6 mg. (See 'Mitchell's Manual of Assaying,' page 755.)

In applying this method it was learned that a very cheap compound microscope could be easily fitted with the scale, which may be had at any good optical goods house. The complete instrument that I have used cost only $5—$3 for the instrument, and $2 for the scale. After receiving the instrument it should be tested. For this purpose several little beads, in their cupels, may be sent to the nearest school of mines, where the diameters can be measured with a standard instrument. These beads of known diameter are now examined under the new instrument and the number of divisions covered by each bead is read. From these measurements the width of each division is calculated. If the instrument purchased has a factor given, use that. As example, your microscope might come with a factor: 1 mm. = 0.033 or 0.028. In such a case, simply multiply the width of each division by the number of divisions covered by the image of the bead and then refer to your table, or, in the absence of that, calculate the weight by using the formula given.

Operating Costs at Mines Near Reefton, New Zealand

The Blackwater, Progress, and Wealth of Nations mines, controlled by English companies and in charge of A. Winter Evans, are in the Reefton district of the South Island of the Dominion, and the following costs per ton are given in the report for 1913:

Department.	Black-water.	Progress.	Wealth of Nations.
Mining:			
Labor and salaries	$2.00	$1.60	$1.34
Explosives	0.10	0.06	0.04
Timber	0.34	0.23	0.25
Air-compressor	0.13	0.06	0.09
Ore transport	0.13	0.25	0.13
Maintenance of drifts, cross-cuts, etc.	0.18	0.27	0.17
Pumping and baling	0.06	0.01	0.02
Hoisting	0.29	0.40	0.51
Drills, sampling, etc.	0.23	0.22	0.29
Total mining	$3.46	$3.10	$2.84
Milling and treatment:			
Ore transport	$0.04	....	....
Rock-crusher	0.03	$0.02	$0.04
Stamping	0.29	0.33	0.62
Concentration	0.03	0.13	0.05
Tube-milling	0.06	....	....
Cyaniding sand	0.32	0.24	0.33
Re-treating old tailing	...	0.18	....
Disposal of concentrate	0.06	0.16	0.08
Total ore treatment	$0.83	$1.06	$1.12
General expenses, including taxes, insurance, salaries, supplies.	$0.61	$0.36	$0.46
Bullion charges	0.12	0.08	0.12
Total costs per ton	$5.02	$4.60	$4.54

Mining costs are high on account of the narrow lodes worked, faults, and bad ground. In the Blackwater the lode is from 11 to 24 in. wide, in the Progress from 51 to 58 in., and Wealth of Nations about 35 inches.

The stamp-mills and cyanide plants showed the following results:

	Black-water.	Progress.	Wealth of Nations.
Ore crushed, tons	45,053	34,996	23,661
Sand cyanided, tons	24,080	19,010	15,275
Concentrate produced, tons	462	442	152
Value of ore treated, per ton	$11.07	$6.73	$9.65
Recovery, per cent	84.19	80.37	78.89

Progress ore contains arsenic and antimony. Accumulated slime is to be treated later, so raising extraction.

MAGNESITE PRODUCTION of the United States in 1913 was 9,632 tons valued at $77,056, against 10,512 tons and $84,096 in 1912, according to the U. S. Geological Survey. California was the only producing state.

GOLD OUTPUT of the Rand in August was 711,917 oz., worth £3,024,037, compared with 728,096 oz., valued at £3,092,754 in August of last year.

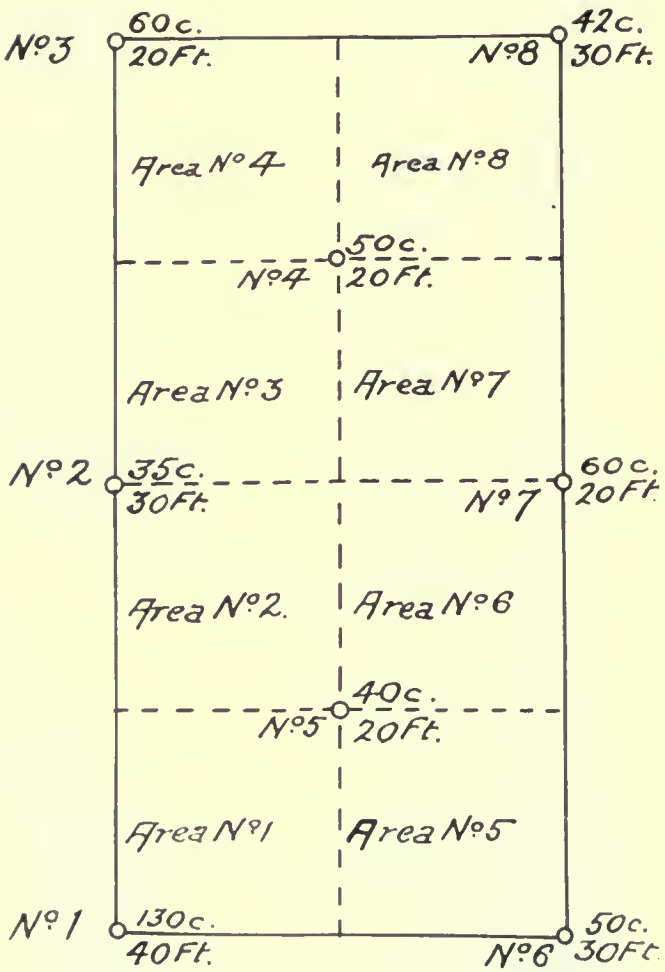
DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Valuing Placer Ground

The Editor:

Sir—Referring to Mr. Herrick's letter, on 'Valuing Dredging Ground,' in your issue of June 27, it may be of interest to note that if the average value of the area 'A' shown in the sketch be calculated by taking the average of the values and depths of the holes at the opposite corners of each of the 8 squares, into which the figure may be divided, as representative of each of the



squares, and taking the area of one of these squares as unity, the result will be as follows:

Area 1..... $\frac{130+40}{2} \times \frac{40+20}{2} = 85 \times 30 = 2550$

" 2..... $\frac{40+35}{2} \times \frac{20+30}{2} = 37.5 \times 25 = 937.5$

Area 3..... $\frac{35+50}{2} \times \frac{30+20}{2} = 42.5 \times 25 = 1062.5$

" 4..... $\frac{50+60}{2} \times \frac{20+20}{2} = 55 \times 20 = 1100$

" 5..... $\frac{50+40}{2} \times \frac{30+20}{2} = 45 \times 25 = 1125$

" 6..... $\frac{40+60}{2} \times \frac{20+20}{2} = 50 \times 20 = 1000$

" 7..... $\frac{60+50}{2} \times \frac{20+20}{2} = 55 \times 20 = 1100$

" 8..... $\frac{50+42}{2} \times \frac{20+30}{2} = 46 \times 25 = 1150$

190 10,025

$\frac{10025}{190} = 52.76$c, average value for area 'A,' or 2.13c. less than the value obtained by Mr. Herrick's method of calculation.

R. C. Jennings.

Plymouth, California, July 18.

[This discussion is bringing out such a variety of methods of calculating results, that there is evident need of more light. Who else has comment?—Editor.]

Solution Control in Cyanidation

The Editor:

Sir—In reply to E. M. Hamilton, who writes in your July 25 issue on the above subject, I would like an opportunity to point out that his letter does not deal in any way with the method of testing which I condemned in my original article, except in one instance where he seems to be in agreement with the views I hold.

The method I originally criticized was clearly referred to as (1) having been in general use since the commencement of the industry; (2) as giving an end-point indicated by a precipitate of silver cyanide; and (3) as being advocated in the most recent text-books. In continuing the discussion and in reply to Mr. Colbath I summarized these points by heading the paragraph

Liebig's Method.—Mr. Hamilton now enters a spirited defence of a titration test which is not only used by himself but by many other independent workers of his acquaintance; and he protests against what he terms an unkind assumption that I have considered himself and a number of his colleagues as 'hopelessly at sea.'

It is difficult to clear one's self from an accusation which has no connection whatever with the facts of the case. Has the method which Mr. Hamilton so ably defends against imaginary attack been in use since the

commencement of the industry? Obviously not because the first detailed description of its application only now appears in the technical press. Is the end-point in Mr. Hamilton's test indicated by the formation of silver cyanide or silver iodide precipitate? By no means. Mr. Hamilton explains that it is usually considered to be due to precipitation of zinc, and would presumably be cyanide of zinc. Is the method advocated in recent text-books? I have seen no mention of it. Is it Liebig's method? Most certainly not.

Had Mr. Hamilton referred to my article, instead of Mr. Colbath's criticism, he would have seen that the method he advocates was not even mentioned. As a matter of fact, it was quite unknown to me at the time. Had he scanned the summary of tests he would have been in no doubt, as he says he was, as to what end-point I titrated. Had he read the article he would have found that I expressly mentioned the necessity for the measurement of all correctives and indicators, and so would have avoided the publication of attempts to disprove my results by using indicators without regard to amount.

While thanking Mr. Hamilton for coming forward with his results, I would like to say that I have nothing to add to or subtract from the figures I published last September. In both the neutral solution free cyanide test, as well as in Green's alkalinity test the final conclusions were only made after several thousand experiments, extending over twelve months, had been performed. Every effort was made to demonstrate any defect, or the superiority of any known method. Mr. Hamilton infers that the reactions and the results would have been different had I used lime instead of 'caustic' in my experiments. I cannot admit that lime is not a caustic alkali, neither can I follow Mr. Hamilton when he suggests that the addition of calcium hydroxide, instead of sodium or potassium hydroxide, would have resulted in a materially different reaction.

The solutions used in my tests varied widely and the method proved reliable even under artificial alterations of alkalinity, zinc, and cyanide content. On the other hand, no implication was made that the methods were suitable for universal application, but under the conditions the publication of the results seemed a normal procedure. I am sorry that Mr. Colbath and Mr. Hamilton object and, in doing so, protest against a slight on them and their colleagues which I have ventured to show exists only in their own imaginations.

A. W. Allen.

London, August 30.

[This discussion has elicited much of interest to cyaniders, and we thank them, in behalf of their fellow workers, for their contributions. We believe the discussion may well stop here. There are so many variables to be considered under working conditions that great exactness is not to be expected. After all, operators do know what to do if their solutions show extraordinary variations, and that is the main point. Until much more laboratory research be completed, we must rest content with that.—Editor.]

The Harrimans and Mining

The Editor:

Sir—An editorial paragraph in your issue of September 5 calls attention to the fact that on the death of any prominent financier, his holdings of mining stocks are usually found to include those of unsuccessful corporations.

Why not? The recent discussion on prospecting in your columns has clearly indicated that, even with the exercise of sound preliminary judgment, the majority of prospects ultimately prove to be failures. Yet one successful mine will make up for a score of such failures; and unless somebody is willing to develop prospects, despite a large proportion of failures, there will soon be no mines.

I know nothing of the specific unsuccessful mining ventures into which J. P. Morgan or E. H. Harriman entered; but I suggest, as a general proposition, that such men are just the proper persons to divert some part of their surplus into speculative mining ventures. They are in a position to obtain good advice, and, if necessary, to finance to any required extent a mine which shows promise. From the point of view of the miner, when I hear of some prominent financier backing a prospect, whether successfully or not, I feel that he has to that extent at least recognized an obligation which he owes to the industries that made his wealth. More power to his elbow; and better luck next time!

George E. Collins.

Denver, Colorado, September 22.

[We cordially agree with our correspondent that any wealthy man who spends part of his income in developing mining prospects deserves encouragement. We also agree that there must be numerous failures to make one success in this work. The 'investments' we had in mind, however, were of another sort. They were in companies that had been floated at fancy capitalization without, in some instances, any reasonable chance of success. As business ventures they were unsound, regardless of the probability or lack of probability of the prospect involved making a mine. The big men in business have not taken, and do not take, the making of a mine seriously, and they do not use in their mining ventures the same shrewd sense, nor do they utilize the technical advice, that they do when going into shipping, railroads, or ordinary commercial ventures. They bet foolishly on one prospect, often poorly chosen, nearly always managed by incompetent men, and when it fails they condemn mining. We have seen many cases where a good prospect and an excellent chance of making a mine failed for such causes.

All of us have seen metallurgical tombstones erected by wealthy men, men who had many successes to their credit, but who when entering the new field attempted the impossible, not even knowing that it was impossible. By all means welcome the Harrimans and Morgans to mining, but try and give them a chance to save their capital if they cannot make money.—Editor.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COARSE-CRUSHING PLANT of the Miami mine, Arizona, delivers ore of which 99% is reduced to half-inch size for the mill bins. Improvements during the past half-year have been responsible for this.

LEAD POISONING is prevalent in pottery industries. In the Staffordshire plants, England, from 1898 to 1912, there were 778 cases, but the complaint is decreasing and is now only 14 per 1000 employed, there being 5290 persons in the lead processes.

THE DOUBLE CYANIDE OF ZINC and an alkaline earth metal is undoubtedly a part-solvent for silver and gold when it occurs in working cyanide solutions. It is, however, unavailable as a solvent for zinc, so that the solution should contain active free cyanide, in addition to the double cyanide, before precipitation can be effected.

EXCAVATION by Americans at Panama totals 238,845,587 cu. yd. to date. Slides have increased the amount by 35,158,225 yd. There remains 14,772,224 yd. to be moved, of which 4,581,692 yd. is in the central division, mostly slides. After having handled 18,908,540 yd. of material in six years, the suction dredge *Culebra* has been retired from service. In that time it lost only 177 days, or 8.08% of the total possible.

DREDGING done by 51 bucket-dredges, 26 pump plants, and 15 jet-elevators in Victoria, Australia, in 1913, amounted to 16,706,023 cu. yd., yielding an average of 7.4 cents per yard. The report of the Sludge Abatement Board for 1913 has been issued, and among many interesting pictures of resoiling work done in the dredging districts, the accompanying halftone shows how

SHOWING WHEAT GROWING ON RESOILED DREDGED LAND, VICTORIA, AUSTRALIA. IN THAT STATE RESOILING IS UNDERTAKEN EXTENSIVELY IN CONNECTION WITH DREDGING.

wheat grows on this dredged land. The Briseis No. 3 bucket-dredge in the Beechworth district did this work. It is equipped with a belt-conveyor to restore the earthy overburden on top of the dredged gravel. The ground is left fairly level, but it is further graded and then plowed. Early in April 1914 this crop was ripe. The height of bank attacked was 36 ft., and 373,648 cu. yd. was moved for 2145 oz. gold.

WHAT AMOUNT OF COAL HANDLED DAILY will warrant automatic machinery? asks *The Labor Saver*. This is, of course, an academic question with no positive answer. One car a week will easily warrant a portable conveyor to assist the shovelers. One car a day will allow a pivoted bucket-carrier handling coal and ashes to pay a profit. Intermediate amounts are frequently handled satisfactorily by bucket-elevators, and screw-conveyors, while larger quantities, up to say 25 cars per day, use the pivoted bucket-carriers for both coal and ash. The average owner or operator prefers machinery to hand labor for this work at equal costs, and for this reason a great many small power-plants are being equipped at this time with automatic coal-handling machinery.

A FORMULA applicable to the calculation of recovery of valuable constituents of an ore by any process where the feed is separated only into concentrate and tailing, and where the analysis of these three products is known, is as follows, according to Ernest Wander, of Rolla, Missouri:

Taking as a basis 100 lb. of iron ore, which is fed to a magnetic separator,

let x = pounds of concentrate

y = pounds of tailing

and F = per cent iron in feed, divided by 100

C = per cent iron in concentrate, divided by 100

T = per cent iron in tailing, divided by 100

then $Cx + Ty = 100\,F$ (1)

$x + y = 100$ (2)

dividing (1) by T, and subtracting (2) gives:

$$\left(\frac{C}{T} - 1\right) x = \left(\frac{F}{T} - 1\right) 100$$

$$x = \frac{100\,(F - T)}{C - T}$$

Recovery in concentrate =

$$\frac{C\,x}{100\,F} \quad \frac{C}{F}\left(\frac{F - T}{C - T}\right)$$

It is apparent from this formula that the analysis of the three products, feed, concentrate, and tailing is the only information required to obtain the relative proportions of concentrate and tailing, and, knowing these proportions, x and y respectively, is obtained the simple formula: $\frac{C}{F}\left(\frac{F - T}{C - T}\right)$ = recovery.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

Operations of Various Copper Companies.—Copper Exports and Contraband Laws.—New Jersey Zinc Co. Extends Field of Operation.—Australian Zinc Concentrate Diverted to American Smelters.

Several of the copper mining companies have made a further reduction in their output, and the Shannon has shut down completely. The Shannon is one of the companies which has a particularly high operating cost, so that in ordinary times the margin of profit is small.——The British Columbia Copper Co. has also shut down its smelter, although it is continuing the work of developing its orebodies with a reduced crew. Work on the proposed new mill has not yet been started, and will, of course, now be indefinitely postponed. According to the mine management, approximately 10,000,000 tons of 1.85% copper ore, containing 72c. per ton in precious metals, has been developed, and it is suggested that the first unit of the mill will have a capacity of not less than 1000 tons per day. ——It is said that the Granby company's Midas mine in Alaska will begin to produce early in November. It had been hoped by the management that production could be started this last summer, but the delay in securing and erecting equipment and the low price of copper combined to make it impractical to start the plant as soon as had been hoped. ——The United States Smelting, Refining & Mining Co. has deferred the quarterly dividend of 1½% on the common stock, which would have been paid October 15 under ordinary circumstances. In a statement to the stockholders, the management says that the operations of the past nine months have made earnings sufficient to pay the usual quarterly dividends on both common and preferred throughout the year, but in view of the uncertainty in the metal markets, and the fact that the Company is a very large consumer of cyanide without any assured prospect that it will be able to secure a supply in order to continue its gold and silver milling operations after the next few months, it seemed better not to declare the usual quarterly dividend on the common stock, though the regular preferred dividend of 1¾% was declared.

Most of the copper which is being shipped now is going to England. It has, of course, been difficult to get shipments through to the countries of the Continent, and especially since there is question whether shipments to a neutral country might not be really intended for one of the belligerents and so might be held up as contraband of war. Underwriters in London have been warned to use caution in insuring shipments of copper from the United States to Rotterdam, since they might be sent on from Holland to Germany. Exports for the week ended September 24 amounted to 7,854,000 lb. Shipments since the first of September have amounted to 28,174,000 lb., as compared to 41,638,000 lb. in the same period last year. Considering the difficulties of the situation, it will be seen that the exports are surprisingly good. The domestic demand is very fair, and the sales have been made at approximately 12c. f.o.b. New York. The Braden, which made a record production of 4,538,000 in August, will not be allowed to exceed 3,000,000 lb. per month in the future. The 'blister' is now being shipped to New York. The Arizona Copper Co. produced 3,778,000 lb. of copper in August, or a little more than its average for the past six months. As this Company is owned in Scotland, and Great Britain is now our principal copper buyer, the management doubtless feels that it is not incumbent on it to decrease output.

The New Jersey Zinc Co. has purchased additional property to that which it now owns at Friedensville, Pennsylvania, and will start prospecting for zinc ore near the old mines there. The zinc mines of the Saucon valley, Pennsylvania, the chief of them being the Ueberrath, Hartman, and Saucon, were famous 40 years and more ago when the zinc-blende, calamine, and smithsonite, which there occur in numerous fissures in a shattered limestone, were the basis of an important mining industry. The Ueberrath was a very wet mine, and its pumping engine was the largest of the day. Now that spelter is so high, it may well prove possible to work these orebodies, and additional ones may be discovered. The Butte & Superior reports that in August 6425 tons of concentrate, valued at $31 per ton, was made at a cost of $4.23 per ton. This shows a high grade of concentrate and a higher working cost than in July. The Connecticut Zinc Corporation, which was organized not long ago to take over the Oronogo Circle mine in Missouri, is also doing well. This is another famous old mine with an enviable record of profitable operations.

Zinc smelters in Kansas and Oklahoma are preparing to care for large shipments of Australian zinc ores. Several cargoes of zinc concentrate on the way to Liége and Limburg have been diverted and will be landed at Galveston after passing through the Panama canal. From Galveston the concentrate will be shipped by rail to Kansas and Oklahoma smelters. This change is not expected to have any effect on zinc ore prices in this country, as American mines will not be able to supply the demand for spelter, and mines in Joplin not operated for more than a year are preparing to open. There will be a good profit in shipment and reduction of Australian ores, and many cargoes are expected before the first of the year. The smelter at Liége, destroyed in the bombardment, was the largest in the world.

WASHINGTON, D. C.

The Exploration Bill before the House.—The Senator from Colorado Discusses the Leasing System.

Whenever it has opportunity these days for the consideration of business on the general calendar, the House of Representatives is paying attention to the bill for the exploration of coal, phosphates, gas, oil, and potassium, the third of the conservation bills, two others having already passed; one providing for the leasing of coal lands in Alaska and the other providing for the development of water-power on the public lands. The radium bill in the House still remains to be passed.

The exploration bill is giving rise to considerable debate, but more interesting and important is the debate in the Senate on the House bill for the leasing of coal lands in Alaska, which is being vigorously opposed by such senators as J. F. Shafroth, of Colorado, who sees in the bill a wedge to impose the leasing system as a principle to be followed in all forms of mining over which the United States still has jurisdiction. The senator has held the floor for some time and the bill has become the unfinished business of the Senate, indicating that it must be disposed of at some time or other to permit other legislation. It is thought likely that it will pass. Mr.

Shafroth has told the Senate that the leasing system is not right; that it was not contemplated by the forefathers in framing the Constitution; and that it is inconsistent with our form of government. A leasing system, he declared, means perpetuation of title in the government, which means exemption from taxation forever. You cannot, he pointed out, have a state or territory perform its functions of maintaining a government republican in form unless it has the power to levy taxes on all lands. To impose a royalty upon a people of a state, he asserted, is imposing a tax by the federal government which has never been imposed upon any other state or territory, and it is, moreover, a tax upon the consumer. "It is a tax," he said, "which when it reaches the consumer is many more times the royalty imposed by the government." He also declared the leasing system to be inexpedient, in that it created a great bureau and imposed federal offices in the states with respect to which the states have special interests and which has never been received by the people with welcome. He instanced the forestry bureau, which, he said, by controlling local affairs seeks to defeat the chief end of government among the citizens affected. He declared the federal leasing system to be impracticable. If the rental is low, the system will not be supporting, he said, and if high it produces an increased tax on production. The double jurisdiction of nation and state especially made the leasing system impracticable in that it would be productive of dissatisfaction, irritation, and litigation. He showed that even in the states a leasing system would be a failure because, he said, it creates a fund which takes the place of taxes for the support of the government among the very people who pay royalties. Colorado, he pointed out, has a sale and leasing system under which it leases considerable of its grazing lands, but it is able to maintain only nominal rentals. It would be more remunerative for the state, he asserted, to give its lands away, for thereby it would derive some substantial taxes for its revenues. The leasing of coal lands, he said, would prove a special failure in that as competition is sharp in the coal-mining business, no operator can hope for success unless he has the most improved machinery and the best facilities for mining and marketing his product. In nearly every instance, enormous capital must therefore be invested, and a railroad must be built to the mine from the nearest operated line. Men will not make large investments, he said, when they can obtain only a lease, subject to forfeiture on failure to perform any of its provisions. The senator examined the cost of coal under ownership and the leasing systems, saying that under the system of ownership in the United States the proprietors have produced the cheapest coal in the world and yet paid the highest wages to miners. The senator said private ownership and operation of coal mines in the United States, compared with public ownership and leasing elsewhere, was approximately saving a million dollars a day to the industries of the United States.

The radium bill, one of the five conservation measures, has been side-tracked for the present in the House. It was expected to follow the exploration bill, but the leaders deemed the consideration of the Philippine bill as more imperative; so this bill displaced the radium bill. Republicans charged that the Democrats were consorting with the 'radium trust.' There seems to be even less chance now of the passage of the act establishing the proposed commission for codifying the mining laws, or any general legislation providing for leasing mineral lands. The Alaska act will probably be pushed through. There is much interest in Washington in the appointments soon to be made to the new interstate trade commission and a disposition to concede at least one place to mining men. Among those favorably mentioned are J. F. Callbreath of the Mining Congress, E. W. Parker of the Geological Survey, and Hennen Jennings.

HOUGHTON, MICHIGAN

EMPLOYMENT FOR COPPER MINERS AND OTHERS BEING FOUND.—NEW COURSE AT MICHIGAN COLLEGE OF MINES.

With several of the mines closed, the Calumet & Hecla properties on three-fourths time, others working only half time, and all the employed working at reduced wages, the people of the Michigan copper country have before them the most serious problem of what to do for the workingman to better prepare him for the approaching winter. Every possible means is being considered to solve this problem. The recent strike not only placed the mining companies in such a financial position that they were not able to carry on full operations for even a short time, under the present market conditions, but it also left the miners in a more serious condition. Dividends have been passed by the mining companies, expressing their desire to consider the workingman rather than the stockholder. The road commissions of Houghton and Keweenaw counties are undertaking the building of new highways for the relief of the men affected by the closing and curtailment of the mines. Gangs of 40 and 50 men are being put on the roads as fast as needed. Married men are given the preference, and no single men will be considered until all the married men have been given employment.

That not only one class of men, but that all workingmen of the copper country are being given an opportunity to do something, is shown by the recent announcement of the Michigan College of Mines. This institution this fall will depart from

MINING AND ENGINEERING BUILDING OF THE MICHIGAN COLLEGE OF MINES AT HOUGHTON.

its previous high standard of entrance requirements and will admit to special short courses all practical men who can read and write the English language. While this step is not temporary, but rather has been under consideration for many years, its introduction at this time is most opportune. No doubt there are many men who, under the present lull of mining operations, will find the time and means to avail themselves of this opportunity to gain technical training for advancement in their particular line of work. Not only will the workmen who lack technical education, but many technically trained men, who in their practical experience have felt the need of more training in certain branches of their profession, will be given an opportunity to better themselves. This extension of the mining college offers an unusual opportunity to the practical men of the iron and copper countries.

Considerable interest is being taken in recent developments of the Calumet & Hecla White Pine property. The mine is at the extreme southern end of the district in territory which, except in one or two places, is practically unexplored. It is reported that a new and rich copper lode has been cut by the diamond-drill.

LONDON

FINANCING CORNISH TIN MINES, AND ACTION OF BANKS.—DEATH OF GILBERT PEARCE.—UNSATISFACTORY CONDITION OF DOLCOATH MINE.

In my last letter I referred to the disastrous effect of the war on Cornish mining, and mentioned that the firm of Bolitho had undertaken to lend money to the mines on the security of the tin concentrate. The Cornish smelters are not inclined to buy concentrate except at an inordinately low price, which is unacceptable to the mines, and a deadlock has ensued, the concentrate being stored until some new situation develops. The mines with little capital back of them are glad to avail themselves of Bolitho's offer, and thereby to keep operations going on a small scale. This action of Bolitho's is of more than passing interest, for it illustrates a phase of modern banking to which attention is being drawn nowadays, when contrasting the difference in England and Germany as regards the relationship of bankers to traders. It is said that English banks do not help to finance business ventures in the generous way that is customary in Germany. It may be mentioned, however, that, in the old days of private banks and of joint-stock banks of limited areas of operation, the industrial enterprise could obtain advances readily. The bankers knew their customers personally and were able to gauge their credit. A mine could at any time be allowed an overdraft, if its general credit and conditions were good. But when the policy of absorption of country banks by the large London institutions was commenced, the personal factor between banker and customer was gradually eliminated. The terms on which money was lent became stricter. The responsibility of a manager of a private bank was great, but his responsibility as manager of a local branch of a big London bank is made practically nominal. His individuality is suppressed in favor of an organization that threatens to be mechanical. Such things as loans to mines became quite impossible. The family of Bolitho were the owners of one of the great West Country banks, and in old days used to be a great help to the Cornish mines. But since the absorption of their bank by Barclay's, this phase of finance has come to an end, and it has been left for the Bolithos to undertake the lending in their private capacity as merchants. It will be remembered that the family had for many years a tin-smelting establishment at Chyandour, just outside Penzance, and it is only two years ago since they suspended operations.

While writing on tin smelting in Cornwall I have to record the death of Gilbert Pearce, who was head of Williams, Harvey & Co. at Hayle for many years. He was brother of Richard Pearce, who was so well known in Colorado as a pioneer in metallurgy. On his return from America a dozen years ago to his native land, Richard Pearce greatly assisted Williams, Harvey & Co. financially, and gave to its service his two sons. With a view to handling foreign concentrate to greater advantage a new smelter was built near Liverpool. The old plant at Hayle was kept in commission, but with Gilbert Pearce's death it will probably be closed, as it will be as cheap to ship Cornish produce at Liverpool as to treat it locally. Gilbert Pearce did not confine his energies to Cornish smelting by any means, for he was on the board of several mining companies working in Cornwall and the Malay States, and he helped greatly in the flotation of many of the Malayan properties in Cornwall under the leadership of James Wickett, the Redruth stockbroker.

As if Cornwall had not enough troubles, arising from the war and the low price of tin, an additional factor is the dismal outlook at Dolcoath, the premier mine of the county, and both historically and currently, one of the great mines of the world. About a year ago I mentioned that the developments at depth were unfavorable, and that the manager, R. Arthur Thomas, had decided to start a policy of prospecting parallel veins from the upper levels. Unfortunately, the results have been uniformly disappointing. Now comes the news that during the past six months the work at the bottom of the mine, at 3300 ft., has disclosed no cassiterite worth working. During the half-year from January to June, the output of tin concentrate, and the yield per ton, were the smallest on record since the present company was formed in 1895; whereas 1015 tons was obtained from 28,717 tons of ore during the first half-year ended December 31, 1895, only 728 tons was recovered from 57,254 tons during the half-year under review, the produce per ton falling from 79 to 28½ lb. In spite of this drop in grade, the Company might have made a divisible profit had not the price of tin been falling recently. The average price received for concentrate during the half-year was £92 14s., as compared with £134 13s. during the first half of 1913. But it must be remembered that in the years 1895 to 1898 the prices received for concentrate were far lower than have ruled since 1910, the average of the former years being less than £40 per ton. The total sum received from the sale of concentrate during the year was £67,544 or 23s. 7d. per ton. The gross profit was £5013, out of which £4502 went to A. F. Basset, the 'lord' or owner of the mineral rights, so that the Company was left with a nominal profit of £510. No allowance has been made for depreciation. The outlook for the mine is, therefore, desperate. Malcolm Maclaren has been conducting a geological investigation with the object of ascertaining the most promising places for future development. His report has not yet been presented. It is to be hoped that it will be published in full, as it should constitute an important contribution to the study of ore deposits. Nobody can blame the secretary, F. W. Thomas, for accepting a post with Williams, Harvey & Co. at their Liverpool tin-smelting establishment. He has given his best to Dolcoath for 30 years, for he joined the staff in the business department in 1883, and he has been secretary of the present joint-stock company formed in 1895 from the beginning. His acquaintance with the commercial aspect of tin must surely be unrivaled, and his knowledge will be of great advantage to the firm that has now the largest tin-smelting business in England.

GRANTS PASS, OREGON

NEW RAILWAY IMPROVES DEVELOPMENT OF JOSEPHINE COUNTY.—WORK AT THE OLD CHANNEL GRAVEL MINE.—OREGON GOLD MINES CO.'S PROPERTY.

Mining in western and southern Josephine county has been greatly stimulated by the completion of the first 12-mile unit of the municipal railroad being built from Grant's Pass toward Crescent City, California. The copper mines of Waldo, Slate Creek, and Butcher Knife have increased their development crews, and ore is already being hauled from some of these to the end of the line for shipment by rail. Trains are now making regular schedule over this first portion of the line. Ore, logs, and other products of the district are received by the new road at Wilderville for shipment to any point in the United States, the cars being transferred at Grant's Pass to the main Southern Pacific line. Mining men have found that they can save considerable in both time and money by hauling by wagon to Wilderville only and making rail shipment from this point rather than at Grant's Pass. From the amount of shipments promised, it appears that the new line will be kept in active operation while awaiting the building of the remaining portion. This 12 miles of the proposed road was built and equipped at the expense of the people of Grant's Pass, who voted bonds for the purpose to the amount of $200,000. With this much built, the city hopes to meet no great difficulty in securing capital for completing the remaining part to Crescent City, thus giving a direct route to San Francisco.

Extensive improvements have been made this summer on

the Old Channel hydraulic mines, of Galice district, for the purpose of operating the properties on a large scale the coming season. The mines have been virtually idle during the past two years, owing to legal difficulties. But this trouble is now removed, and the recent improvements will allow the operation of the extensive diggings to their full capacity. Water is available by two long ditches from Tom East and Galice creeks for three 6-in. monitors working under 450 and 500-ft. gravity head. The banks are from 180 to 300 ft. high on Slate bedrock, with coarse gold on the lower strata and finer gold above. The properties are heavily timbered, and the natural dumping facilities are of the best.

James O'Grady, manager for the Oregon Gold Mines Co., states that he is meeting excellent success in the reduction of the upper level ores lately uncovered on the Granite Hill and from the Ida claim on the same property. Ten stamps of the mill will be kept in continuous operation on this low-grade though free-milling ore. In the meantime the large hoist is operating a double skip day and night in removing the water from the mine, and the level is being steadily lowered.

SILVER CITY, NEW MEXICO

CHINO COPPER OPERATIONS.—FLOTATION AT BURRO MOUNTAIN.—RICH GOLD AND SILVER ORES OPENED.—EMPIRE ZINC CO.'S WORK.—WHITE OAKS DISTRICT.—ASSESSMENT WORK EXEMPTION.—MOLYBDENUM ORES.

The concentrator of the Chino Copper Co. at Hurley is treating ore from Santa Rita 5½ days per week instead of 4 days as was the schedule during the beginning of the European war. Several buildings are being erected in Hurley by the Company, and extensive road improvement south to Whitewater is under way. The newly erected ore-crusher at Santa Rita, which prepares all ore from pits for grizzlies at the mill, is in operation and is giving satisfaction.

A new flotation unit has been ordered for the experimental mill of the Burro Mountain Copper Co. (subsidiary of Phelps, Dodge & Co.) at Tyrone, and is expected to arrive this week. It is claimed that flotation experimenting in the past has been unsatisfactory, but complete demonstration will be made before the process is discarded. A Hardinge conical mill is giving satisfaction in the experimental plant. The plant is expected to commence operation in a few days and will treat ore from the Chemung dump, which is the same character as all ore developed in the mines. The Diesel engine being installed in the power plant is nearly finished.

Five sacks of high-grade gold ore, averaging $60,000 per ton, have been taken from a pocket in the Pacific vein by Wright and Stauber, lessees of the Savannah Copper Co.'s property. Shipment will be made from the bank to a San Francisco refinery. Operators of the Silver Cell mine, in the same district, are contemplating the installation of a compressor and air-drills. They have cut a vein of high-grade silver ore lost on account of faulting some years ago. Beautiful specimens of native silver are being shown by operators at Pinos Altos.

A tramway from the Cleveland mine of the Empire Zinc Co. to the Santa Fe railroad at Silver City, New Mexico, is under consideration by the Company. Title of the ground is being investigated for right-of-way purposes. The tram will be 10 miles long. Men in a position to know think the Company will erect a mill for concentration of its zinc sulphide ores within a short time. Many road improvements have been made by operators.

The annual meeting of the stockholders of the Parsons Mining Co., operating at Nogal, Lincoln county, and with Eastern offices at Mishawaka, Indiana, was held September 20 and the following officers elected: J. H. Fulmer, Jr., president; George H. Fuller, vice-president; A. G. Graham, secretary; and A. B. Graham, treasurer. The Company has entered into a contract with the Wild Cat Leasing Co., of White Oaks, whereby it will be supplied with electric power by the latter Company for the operation of its mines and mill. The Wild Cat Leasing Co. has ordered a 500-kw. steam turbo-generator from the Westinghouse company which will be ready for operation by January 1. The Parsons Mining Co. will commence the installation of the power-transmission line at once and will overhaul its mill so as to be ready when power is turned on the first of the year. A. T. Anderson is superintendent of work. The Wild Cat Leasing Co. has made remarkable progress in the White Oaks region, and is now dropping 15 stamps, 20 hours per day, on ore from North and South Homestake mines. The Yellow Jacket iron mines at White Oaks are under lease to Swoyer and Evans. Preliminary work has been done and shipments are being made to the Pueblo smelter, Colorado.

Prospects for reconstruction of roads to Red River, Taos county, are brighter than they have been for years, and a party of government surveyors is laying out the new grade. Concentrating tables are to be added to the June Bug mill

MAP OF NEW MEXICO.

equipment at once, necessitated by the recent find on the Silver Queen vein which has revealed a good grade of ore. No attempt will be made at cyaniding. Concentrate will be shipped to Pueblo, Colorado.

The exemption of mines from annual assessment work for the year 1914 is meeting with a hard struggle in materializing, and the issue has not seemed to awaken favorable sentiment. Harvey B. Fergusson, congressman from New Mexico, introduced the bill giving the demoralization of the mining industry on account of the European crisis as the cause for the act. The Silver City Chamber of Commerce has sent out resolutions and copies of the bill to all similar bodies throughout the Rocky Mountain states, with an effort to create widespread interest in the proposed relief to mine-owners. Many are in favor of its passage, and many are not. The lawmakers at Washington are desirous of hearing from the field regarding the attitude toward the bill.

Molybdenum ore in commercial quantities is being mined and milled in San Miguel county, 16 miles northeast of Las Vegas, in El Porvenir Mountain mining district. There are sixteen claims in the group.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

A report has been recently issued by the U. S. Geological Survey, summarizing its investigations in the Ruby-Innoko-Iditarod gold districts, and this is illustrated by both topographic and geologic maps. The results therein presented indicate that these districts lie in an important gold belt which has already produced gold and silver to the value of nearly $10,000,000. The region is now very inaccessible, and operating costs have therefore been necessarily high. For this reason but little attention has been paid to the gold-bearing quartz veins of the region, some of which give promise of having commercial importance. When the district has been opened up by railroads and wagon-roads, some development of quartz veins will undoubtedly take place, and the gold-bearing gravels of lesser tenor can then be mined at a profit.

Cordova

Accompanied by Caleb Corser, superintendent of the Copper River railroad, Frederick Mears and Thomas Riggs, Jr., members of the Alaska Engineering Commission, have left Cordova for Katalla. From the latter place they will go to the Bering River coalfields, and probably over the proposed lines *via* Lake Charlotte to Mile 38 on the railroad. A survey is under way from this point to a place 10 miles distant, to connect with the surveyed line from Miles glacier *via* Lake Charlotte to the coalfields. The Copper River railroad has already made two surveys to the fields, one from Cordova and the other from Miles glacier or Mile 49.

Fairbanks

Cross-cutting is under way at 150 ft. in the Newsboy quartz mine, and it is hoped to cut the vein in 70 feet.

Juneau

A bonus dividend, No. 109, of 75c. per share, was paid by the Alaska Treadwell company on September 28.——During August the Mexican mill crushed 20,202 tons of ore, and 359 tons of concentrate was treated, for a total yield of $32,984, or $1.63 per ton. The net profit was $7532.——The United mills crushed 39,585 tons and treated 894 tons of concentrate for a total of $83,020. The net profit was $20,358. Development amounted to 1171 feet.

ARIZONA

Cochise County

According to Walter Douglas, general manager for the firm, Phelps, Dodge & Co. has decided to start a profit-sharing scheme whereby employees will participate in profits of the mercantile company under certain conditions.

Gila County

For the first half of 1914 the Miami Copper Co. reports as follows:

Development feet	20,688
Ore treated, tons	638,456
Average copper content, per cent	2.275
Concentrate produced, tons	25,668
Copper output, pounds	19,078,942
Extraction, per cent	69.14
Revenue	$2,716,681
Profit	963,968
Dividends	746,877

All ore was extracted from above the 420-ft. level, that at 570 ft. not having been touched. Mining costs were reduced from $1.46 to $1.17 per ton. This was due to completion of the shrinkage stopes; also by forced ventilation, compressed air consumption was reduced from 9,000,000 to 5,000,000 cu. ft. per month. Since No. 6 unit of the mill was remodeled the residue is reduced to 0.65% copper, and the other five units will be altered similarly. Experiments are being made on flotation and leaching. Milling costs were lowered from 53 to 44c. per ton, due largely to improvements in the coarse-crushing plant.

Humboldt County

At 1200 ft. in the United Verde Extension mine, 14 ft. of chalcocite ore has been opened, 7 ft. of which assays $7 per ton. The formation is favorable for extension, and is similar to that in the United Verde adjoining. According to J. S. Douglas, president of the Company, $225,000 has been spent on the property. The British shaft is to be sunk 200 ft. farther to cut the new orebody at 1400 ft. This and other work will require about $50,000, which will be subscribed for by stockholders.

Mohave County

The Copper Giant mine, eight miles east of Hackberry, which was taken under option a year ago by the United Verde Copper Co., has now been acquired by the Company at $30,000. Under management of William Neagle, $110,000 has been spent in development, resulting in opening $600,000 of high-grade gold-copper ore to 550 ft. depth. Eleven miners share in the proceeds of the sale.——At the Yucca Mining Co.'s property, a good tonnage of gold ore has been opened, and the 10-stamp mill is to start this week.——Six feet of copper ore is showing in the Whale mine in Copper cañon, and on the foot-wall is some rich molybdenum ore.——At 250 ft. in an adit of the Rainbow mine, at Chloride, there has been cut 28 in. of gold ore, with a little lead and iron sulphide. ——The Cyclopic mine is opening satisfactorily for the owner, S. C. Bagg.

Pinal County

At Ray, on September 20, a cloudburst did damage amounting to about $100,000.

CALIFORNIA

Nevada County

(Special Correspondence.)—The Union Hill mine at Grass Valley has been acquired by G. S. Johnson and associates of San Francisco, who have organized a company, called Union Hill Mines, to operate the property. A. D. Cox, formerly of Rochester, Nevada, has been appointed superintendent, and started sinking the shaft from the 600 to the 900-ft. level on October 1. A cross-cut is being driven on the 300-ft. level to open the Georgia vein, which produced a good grade of ore on the upper levels, where the management hopes to develop enough ore to start the mill and keep it running until sinking has been finished. The mine is credited with a production of $2,000,000 above the 600-ft. level. It is equipped with a 20-stamp mill.

San Francisco, September 25.

Dividends of 20c. and 6c. per share, equal to $50,000 and $18,000, respectively, have been declared by the North Star and Brunswick Consolidated companies.

Placer County

Complaints have been made by residents of Fairoaks and

Orangevale that water from the north fork of the American river is being polluted by dredges near Auburn, and the dredging companies will probably be prosecuted.

SHASTA COUNTY

Development of the manganese deposit near Heroult proceeds, and it is 20 ft. wide of good value. Officials of the Noble Electric Steel Co. have been sampling the ore.——A 6.75-ton tumbler for the Trinity Dredging Co.'s dredge at Lewiston is being hauled from Redding to Lewiston, Trinity county.——After a 12-day shut-down for repairs, two blast-furnaces of the Mammoth Copper Co. have been blown in.

SIERRA COUNTY

A power dam is being constructed by the Monarch Consolidated company. Under D. McGonigal a good number of men are employed at the mine, formerly known as the Lee.—— The Colombo claims have been examined by Eastern people.

TRINITY COUNTY

The Trinity Asbestos Mining Co. has been incorporated at Weaverville with a capital of $500,000, Oakland people owning all shares. H. T. Mecums is general manager. About $50,000 has been spent on the property, and production may start before winter. A road 25 miles long will be constructed from Castella to the asbestos camp.

COLORADO

LAKE COUNTY (LEADVILLE)

Another lot of gold ore from the Pat Connors lease on the Jonny mine has been sent to smelters. The two tons will yield about $30,000. In the Sinclair lease the average is 3 oz. gold per ton.——Rich gold-silver ore is coming from the Big Five mine, a new shoot being cut last week.——Mining men

JONNY HILL AND MOSQUITO RANGE, LEADVILLE DISTRICT.

are interested in the sinking of the Davis shaft on the North Side claim on Fryer hill.——The face of the Walker adit in the Mosquito range is nearing the vein, the present length being 512 ft. This ground is a new area in the district to be prospected.——The new Candish mill awaits some special machinery. The zinc smelter is closed indefinitely.——The district generally is in normal operation.

TELLER COUNTY (CRIPPLE CREEK)

At a depth of 1942 ft. the Vindicator company has stopped sinking its main shaft, and will open out at No. 19 level, 1907 ft., or 8302 ft. above sea-level.——The Golden Cycle shaft is down 1925 ft., or 8141 ft. above sea-level; Blue Bird shaft, on Bull hill, 1875 ft. deep; and Portland No. 2 shaft, 1750 ft. ——The Vindicator concentrating plant is nearly completed. ——The United Gold Mines' W. P. H. mine has been leased for three years to Oscar Fogleman of Cripple Creek. Past gold output is over $500,000. W. Stewart has leased the Hardwood mine belonging to the same Company.

Extension of the Rooseveit drainage tunnel is to be continued by the tunnel company for 30 days, when it will call for bids to complete the work, as it will be in a better position to pass on the prices offered. The daily advance in solid formation is six feet. No timbering is necessary, and the frequent caving of dike matter does not hinder mining.

Four-ounce gold ore has been cut at depth near the Lee shaft of the Isabella Mines Company.

IDAHO

BLAINE COUNTY

Gold ore worth $33 per ton has been opened in the El Oro mine in the Skeleton district.——The Santa Clara claims of H. M. Bell are showing good ore in an adit. He will erect a small stamp-mill next summer.——The district is fairly active just now.

CUSTER COUNTY

Colorado people, developing the Charles Raine property in the Yankee Fork district, have cut the General Custer lode, which has produced several millions in gold and silver in the past. On driving through the Custer fault good ore was exposed.——In this district are working the Wall Street and Bonanza properties, the former working by sluicing, and the latter having fair gold ore opened and a 40-ton mill ready for work.

SHOSHONE COUNTY

The Hecla Mining Co.'s mill capacity at Gem has been increased from 300 to 400 tons per day, while several other improvements were made.——In 11 months the H. E. M. company has driven an adit 2276 ft., and has cut the vein.——In No. 2 adit of the Silver Cable, near Mullan, the ore-shoot is 250 ft. long and from 12 to 30 ft. wide, and for 150 ft. there is 5 ft. averaging 40% zinc.——At the Monitor, near Adair and the summit of the divide between Idaho and Montana, an adit has been started to cut a vein at a vertical depth of about 1500 feet.

It is expected that the past summer's mining activity in the Pine Creek district will be continued during the winter. A large tonnage of lead-zinc ore is developed at the Douglas. Work at the Rosie Ann and Liberal King claims is promising. Two prospectors, George Miner and Jack Martin, returned two weeks ago from a three months' trip to the area lying between the St. Joe river and the north fork of the Clearwater. While the mineral prospects are not very encouraging, the country has an abundance of timber.

The Caledonia Mining Co., of Wallace, will pay a dividend of 1c. per share, or $26,000, on October 5. On October 5 the Bunker Hill & Sullivan paid dividend No. 205 of $81,750, making $15,546,750 to date.

MONTANA

SILVERBOW COUNTY

The Bullwhacker Copper Co. is being reorganized, and an assessment of 15c. per share is to be made on 1,000,000 shares to liquidate a $125,000 judgment against the Company.

The Davis-Daly Copper Co. reports, for the year ended June 30, 1914, show a total income of $271,973, charges $379,993, making a deficit of $108,020. There was shipped 52,198 tons of dry ore, compared with 33,352 for the previous year. Since April 1, 1914, operations have been confined wholly to development on the 1400 and 1700-ft. levels, and in sinking the Colorado shaft.

MISSOURI

JASPER COUNTY

A sludge plant and a tailing mill are being built by the National Concentrator Co. on the W. E. Johnson land west of Joplin, and on the United Zinc Co.'s land at Chitwood, respectively. A portable separator, which will remove the barren tailing before it reaches the mill, is to be installed. This is an innovation for this district. It is 8 ft. diameter,

fitted with a funnel shaped screen, sloping to the centre, which works up and down at a rapid rate, like a jig. At the tailing dump this machine will be worked, so reducing the quantity of tailing being re-treated.

NEW MEXICO

Sandoval County

The Bland gold mining district, which has been neglected for years, is again active. A 100-ton mill was recently started by the Cossack Mining Co., which will receive custom ores.

NEVADA

Esmeralda County

The Goldfield Consolidated company's mill treated 27,211 tons of ore in August, yielding a net profit of $128,135. The total cost was $6.24 per ton. In the mine, 2254 ft. of development was done at $7.24 per foot. Lessees produced 1192 tons, worth $21,056, of which the Company received $10,935, less cost of transport and milling.

Housing for the 10 stamps, two 6-ft. Huntington mills, 100-hp. gasoline engine, and other equipment for the Golden Arrow mine, 47 miles northeast of Goldfield, is finished. It is hoped to start the plant on December 15.

Humboldt County

On September 17 the offices of the Codd and Big Four leases were set on fire by incendiaries, as oil-soaked cotton waste was found in the Big Four office.

Lyon County

The Nevada-Douglas mine has been closed temporarily, but construction work on the leaching plant will not be stopped. ——The Mason Valley smelter received 3200 tons of ore last week, and the shutting down of the Nevada-Douglas will mean a considerable decrease to the plant.

Mineral County

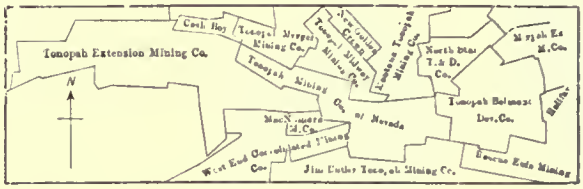
(Special Correspondence.)—The district embracing Luning and its copper prospects continues to be developed even though the present war has had a tendency to demoralize the copper market. This development is due to the perfecting of the leaching system which will treat the ores of this area by this cheap process. Luning is particularly well situated for the leaching process, not only for the oxide ores, but also sulphides, and at the same time is in a position to save gold and silver content economically. Salt is procured at a moderate figure at Sodaville, 12 miles distant, and for fuel for roasting, the coal at Coaldale can be utilized, and obtained at a low price. From the sulphide ores which would necessarily have to be roasted, undoubtedly sufficient sulphuric acid could be obtained to carry on the leaching process. Thus the essentials for this process can be procured very economically at this point. There is water in abundance at Luning. At the plant for leaching copper ore, installed by the Wagner-Azurite company, has been overcome the neutralization of the acid through the lime content of its ore, and is more than a success from the point of saving the metal. This Company is still sinking and is in high-grade sulphide ore that will average 4½% copper, and is 43 ft. wide. The Luning, Idaho, Mining Co. is continuing the working adit and has just cut some stringers, which indicates they are about to intersect the ore on which the shaft is sunk. Last month 18 ft. of high-grade copper ore was cut in this adit carrying some silver, probably the best showing in the camp at this depth. The Alameda mines, controlled by Spokane capitalists, are getting ready to begin work on the large holdings to the south of Luning.

Luning, September 5.

Nye County

Seven mines at Tonopah produced 10,789 tons of ore, worth $220,170, during the week ended September 26.

The Tonopah Mining Co. has made application for a temporary restraining order against the Tonopah Extension Mining Co. from working in or extracting ore from the Sand Grass claim. Suit is also filed for the recovery of the value of 12,000 tons of ore extracted and valued at $200,000. Judgment is asked for this amount, and that the said judgment be



CLAIM MAP OF TONOPAH.

trebled, making $600,000. This makes two extralateral right suits now pending in Tonopah, the other being the Jim Butler and West End case.

White Pine County

(Special Correspondence.)—The Nevada Consolidated continues to run half time, many of the men working 5 to 6 days per week. At the concentrator the Company has installed 12 tables of local manufacture, similar to those being used by the Utah Copper for concentration. More are being made, their results having been satisfactory. The Company is using its own method of oil flotation. It is said that experiments have been made with the oil of the plant called 'rabbit's-foot,' that grows in this country in low ground. The plant burns quickly when green, as it contains so much oil. The staff is trying to find a denser oil. G. L. Sheldon and partners recently located a 100-ft. lode of antimony ore near the old camp of Taylor. It is exposed on the surface for 700 to 800 ft. in length. General samples show 10% antimony, 20c. gold, 30c. silver, and traces of lead and arsenic. It occurs in a hard, dense quartz, in lime-shale formation, with porphyry near, and appears to be disseminated all through with bunches of rich ore.

Ely, September 18.

UTAH

Settlements for copper ore with the American Smelting & Refining Co. have been on a provisional basis, but the Company made the following statement last week: "From July 31 up to and including September 14, 1914, copper was sold by the American Smelting & Refining Co. to cover purchases of copper as made by them during the month of August, and final settlements will be made immediately for the August copper purchased on the average sales price received by them for this copper, which was 12.34c. in New York. For copper purchases subsequent to August 31, provisional settlements will be made as heretofore, with final settlements to follow."

Cañon and Sanpete Counties

Owing to the stoppage of shipments of ozocerite from Austria, the deposits in these counties are attracting attention, and David T. Day and T. Robinson of the U. S. Geological Survey, have been examining them at Colton and Soldier Summit in Spanish Fork cañon.

Juab County

Only one man of the twelve caught by a cave-in at the Centennial Eureka mine has been rescued alive. Recovery of the bodies is difficult. It is thought by J. Fewson Smith, of the United States company, that there was a thick false roof or shell to the stope, which fell upon the timber and crushed it and the men at work. J. T. Moore and J. C. Roberts, of the Denver rescue-car, went to Tintic.

Diamond-drilling is under way from the 1400-ft. level of the Chief Consolidated.——Development at 1900 ft. in the Iron Blossom is promising.——About 100 tons of ore is coming daily from the new shoot at 600 ft. in the Mammoth.

SALT LAKE COUNTY

Word from Salt Lake City indicates that the Ohio Copper Co.'s affairs will be settled, and operations will be continued soon.——The Riverside Dairy & Stock Farm has filed suit for $28,000 against the American Smelting & Refining Co., on account of fume from the Murray smelter poisoning grass, resulting in sickness of cows and the milk being of an inferior quality.——At the Alta Consolidated the adit is in 3650 ft. and is now in a contact of lime and porphyry. It will be driven about 300 ft. farther where this contact cuts quartzite and the southwest fissure, and the Skipper orebody should be cut in about seven weeks. At 1030 ft. above this adit, the orebody contains lead and silver. A. O. Jacobson is manager.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—Mining in and around the Republic district has been dull for some time, but there are signs of improvement. Ore shipments in July and August over the Great Northern line to British Columbia smelters were as follows:

Mine.	Tonnage.	Smelter or mill.
Ben Hur	3386	Anyox, Greenwood, Trail
Rathfon Reduction Works.	264	Grand Forks, Trail
Knob Hill	468	Greenwood, San Poil mill at Republic
Lone Pine	154	San Poil mill at Republic

The Hall Creek Mining Co., in the Enterprise district, east of the Sherman range in the eastern part of the county, has completed its mill. It will be driven by electric power, generated from the Company's own water-power.

The equalized valuation of the principal (28) mining properties of the county for 1914, on which taxes will become due next February, amounts to $425,794. Of this amount, $378,250 is for the Republic district.

Republic, September 20.

STEVENS COUNTY

Ore from the United Copper mine at Chewelah is now being sent to the Trail smelter, British Columbia, a two years' contract having been arranged with the Consolidated Mining & Smelting Co. The Great Northern railroad has reduced the freight on ore by 25c. per ton. At a vertical depth of 1000 ft. in the lower adit, there is 9 ft. of shipping ore. With 75 men the output will be 225 tons per day, 100 tons being shipped and the balance treated at the mine concentrator.

WYOMING

FREMONT AND HOT SPRINGS COUNTIES

Gold placers on Wind and Big Horn rivers are described by Frank C. Schrader in *Bulletin* 580-G of the U. S. Geological Survey. Deposits of gold-bearing gravel occur in many formations up to 15 miles back from the river. Along the main streams the average thickness is 12 to 14 ft. Two dredges have not made profitable recoveries. As a conclusion to the report, the geologist states that a small area at Nebie possibly contains placer gold in valuable amounts, but outside of this ground the average is less than 6c. per yard. A large percentage of heavy sand interferes with gold recovery.

CANADA

BRITISH COLUMBIA

In the long adit being driven by the Portland Canal Tunnel Co. a wide vein of $11 silver-lead ore has been cut.

ONTARIO

The lowering of Cobalt lake is to be started at once, according to M. B. R. Gordon, manager for the Cobalt Lake Mining Co., but it will not be drained until next spring.——On October 20, La Rose Consolidated will pay a dividend of 2.5%, equal to $187,328, making a total of $4,825,135.

YUKON

No. 2 dredge of the Canadian Klondyke Co. had the following record for the week ended September 12:

Operating time, hours (168 hours possible)	161.52
Average depth of gravel, feet	43.1
Gravel handled, cubic yards	102,285
Gravel handled per hour, cubic yards	632
Power used, kilowatt-hours	94,550
Power used per cubic yard, kilowatt-hours	0.92

Water shortage is curtailing work at Mayo. At the Silver King mine, Harry McWhorter states that 59 tons of ore sent to Trail yielded 4.73 oz. gold, 26,752 oz. silver, and 53,244 lb. lead, valued at $15,969, or $269.90 per ton. The total cost was $100 per ton. About 1000 tons is to be mined for next spring. At 108 ft. depth the lode is 5 ft. wide with 34 in. of good smelting ore. Other silver-lead claims are promising. Gold has been found on Kirkman creek, 27 miles above Stewart creek, and 100 miles upstream from Dawson, where some work was done from 1898 to 1900. Bedrock is from 8 to 20 ft., it being a schist.——According to the *Dawson Daily News*, over 1500 ft. of work has been done in the Lone Star quartz mine near Dawson. A 4-stamp Joshua Hendy mill was erected in 1911, and a complete equipment is driven by electric power. A concentrator was added early in 1914. To the end of 1913 the output was $24,081. The Company has spent over $70,000 on the property.——All the Canadian Klondyke company's dredges are busy. No. 1 started on May 6, No. 2 on March 4, No. 3 on May 3, and No. 4, the 'flagship,' on March 30. In August the latter boat handled 102,030 cu. yd. during one week, a world's record. The Company is digging a 5.5-mile ditch for conducting water to Last Chance for hydraulicking. At Hunker the water will be raised 600 ft. by a 16-in. three-stage centrifugal pump driven by a 1200-hp. motor.

COLOMBIA

The Pato dredge of the Oroville Dredging Co. recovered gold worth $17,500 from 32,400 cu. yd. during the week ended August 25.

KOREA

June and July gold returns of the Oriental Consolidated are as follows: 240 stamps worked 22.9 days, crushing 23,932 tons of ore, yielding from all sources $125,880. The 'operating profit' was $52,959, of which $13,695 was spent in development, etc., leaving a net profit of $39,263. The Kuk San Dong 40-stamp mill was hung up for the full month of June on account of shortage of ore; the Candlestick 10-stamp mill was closed for 10 days for the same reason; and the Maibong 30-stamp mill was down for 7 days on account of repairs. In July the eight plants treated 23,158 tons for $124,735. Recovery at the Taracol cyanide plant was 82%. The Kuk San Dong stamp-mill is again at work. On July 4 all mills were closed for the usual celebrations. Rainfall was 22.56 in., and there were heavy rains up to August 6. The hydro-electric plant is furnishing 400 hp. for the Taracol mine. The August clean-up should be an increase on July.

MEXICO

(Special Correspondence.)—Railway officials report that train service as far as Torreon is being maintained regularly with occasional trains through to Mexico City, but they undertook to make no guarantees as to service. Constitutionalist soldiers were expecting to be ordered south at any moment. It is felt here that the fundamental difficulty between Villa and Carranza is over the land question. Carranza, it is said, purposes to compensate the large land-owners for the estates that are to be divided, while Villa insists that the lands were originally stolen and should be returned to the people without compensation. Others say it is a mere matter of who shall be boss.

Juarez, September 24.

Official advices from Mexico City to the State Department at Washington on September 30 announced the issuance of a decree annulling all mine titles granted during the Huerta administration. The department issued this statement: "Sixty days from the date of the decree annulling the titles are allowed mining agents to make applications for the renewal of all procedure previously taken. All payments required in connection with mining titles or mining claims must be made again to the present central administration."

Full details of the deaths of the late president Madero and vice-president Suarez have been published in Mexico City. A description of the incident was given by Mexican chauffeurs who drove the automobiles at the time. The men are said to have been killed by Major Francisco Cardenas and three officers of *rurales*, the chauffeurs being shot at also, but escaping under dire threats.

Coahuila

The eight groups of coal mines in the northern part of this state, which prior to the revolution produced all the coal used in Mexico, are being drained and reopened, according to the *Mexican Herald* of September 19. The Palau mines are yielding 10,000 to 12,000 tons per month, which is being used by the Constitutionalists. The Escondida and Agujita mines are producing 6000 tons between them. Considerable damage has been done to the Esperanza, Rosita, Lampacitos, Cleote, and Menor coal mines, most of them being full of water. The Rosita belonged to the Madero family, and was dynamited during the trouble. There is a large shortage of labor for the mines, as the 7000 or 8000 men previously employed joined the Constitutionalist army. The National railways are using 800 tons of coal per day in the southern division, also 5000 bbl. of oil. The latter fuel is used on the Interoceanic line, while the Pan-American line uses 3000 cords of wood per month.

Shipments of crude oil from Tampico to the United States during June 1914 totaled 1,062,062 bbl., or 86,156 bbl. less than in June of last year. The decline is the result of disturbed political conditions. Of the shipments during June this year, 238,841 bbl. went to Galveston, 165,385 to Port Aranzas, 131,577 to New York, 113,363 to Sabine, 89,000 to Baltimore, 84,000 to Port Arthur, 69,249 to New Orleans, 59,319 to Tampa, 56,328 to Perth Amboy, and 55,000 to Wilmington, Delaware.

Sonora

(Special Correspondence.)—At San Javier, work at the lixiviation plant and refinery at the Wyman mine, operated by W. C. Laughlin Co., has been stopped. With the exception of pumping at the Animas shaft, all work has stopped at both coal and metal mines; this also applies to concentrator construction. On June 26, in defending the bullion truck against robbers, the mill superintendent, Thomas Farrell, was killed. On August 6, the Yaqui Indians held up a bullion train, killing Arthur Squires, an employee, and several Mexicans, securing 36 bars of silver. Since this time they have destroyed considerable supplies en route to the mine and have made it impossible to secure provisions and supplies for operation. Due to political troubles, the Company has not been able to secure protection.

Nogales, September 21.

(Special Correspondence.)—In spite of war conditions and many hardships in the country, development of the San Manuel, San Jose, and Cacharamba mines has been kept on with few interruptions during the past two years. Work done amounts to 600, 1200, and 1100 ft. respectively. The San Jose has a new 6 by 8-in. hoist, and a new one is to be installed on the Cacharamba in October. The latter mine is the most promising one in the district, and produces ore assaying 85 oz. silver and second-class of 23 oz. per ton. Several arrastres have been worked at the San Manuel, which is owned by Don Rafael Ibarra. Work has been resumed at the Claraboya mine.

Tempe, Arizona, September 24.

PERSONAL

Charles C. Selbie has returned from Korea.

J. E. Clennell has returned to Oakland from Cobalt.

Charles G. Yale is confined to his home by sickness.

W. J. Loring sailed for China on the *Manchuria* Saturday last.

Robert Holmes returned to St. Louis from California this week.

James W. Malcolmson and Lester R. Budrow were in San Francisco this week.

J. Parke Channing is making a good recovery from an operation for appendicitis.

Death of E. B. Preston last Saturday is announced. An obituary will appear later.

J. A. Burgess, superintendent for the Nevada Wonder Mining Co., was in San Francisco this week.

E. F. Burchard is working in the Southern Appalachian ironfields. Later he will go to eastern Texas.

Charles Smith, president of the Old Dominion Copper Co., is at Globe, Arizona, on an official inspection trip.

C. A. Botsford has accepted the position of mining engineer for the Ernestine Mining Co. at Mogollon, New Mexico.

Cutler B. Whitwell is at Forbestown, Butte county, California, on examination work. He will be at that place for the next six weeks.

After long illness and tedious convalescence, F. H. Mason has resumed work and is attached to the mineral staff of the Canadian Commission for the Panama-Pacific International Exposition.

S. H. Brockunier has just completed an examination of the property of the Jardine Gold M. & M. Co., at Jardine, Montana, and of the property of the Yellowstone Cement Co. near Gardiner, Montana.

Otto Ruhl, in charge of the mining exhibit from Jasper county, Missouri, for the Panama-Pacific International Exposition, has many attractive exhibits promised from the operators of that district.

John W. Mocine, who resigned last January as superintendent of surface plants for the Goldfield Consolidated Mines Co., and as manager for the Goldfield Merger Mines Co., to become general manager for the National Copper Mining Co. property at Mullan, Idaho, has returned to Goldfield to again hold the position of superintendent of surface plants for the Goldfield Consolidated Mines Co., succeeding Joseph K. Poe.

SCHOOLS AND SOCIETIES

The secretary of the Canadian Mining Institute has received a letter from G. C. Lloyd, general secretary of the Sixth International Congress of Mining, Metallurgy and Applied Geology, stating that in consequence of the war, the meeting that was to have been held in London during July 1915 will be postponed indefinitely and all preliminary arrangements have been canceled.

The Utah local section of the American Institute of Mining Engineers will hold its first annual meeting at the Commercial Club, Salt Lake City, Utah, on October 10. The principal business before the meeting will be the election of officers for the ensuing year. The committee appointed to nominate candidates for the offices has submitted the names of R. C. Gemmell for chairman, C. W. Whitley for vice-chairman, and Ernest Gayford for secretary-treasurer.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, October 1.

Antimony	15 —15¾
Electrolytic copper	13⅝—13⅞
Pig lead	4.00— 4.95
Quicksilver (flask)	$50— 60
Tin	36 —37½
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	15

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 1.—All metals are weak. Lead is quoted at 3.75c. and spelter 4.85c. per pound.

On September 24 the Bank of England reported that its gold reserve amounted to £51,673,000 ($258,300,000), the largest amount ever held by the institution.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

No average for September can be given yet, but it should be around 54c. Prices in New York and London on October 1 were 52¾c. and 24d. respectively. Some mining men look for a rise in the metal for the following reason: India has large reserves of gold, and England needs this for war. This metal may be drawn on to a great extent, necessitating imports of silver to take its place, so opening a good market. Writing on September 17, Samuel Montagu & Co. reported that the trend of prices in London was downward, notwithstanding that supplies were not plentiful. There was a continued absence of support from the East (India and China). On account of the war a large demand for silver coin is likely to continue for some time to come. One thing is plain, the character of the market is such that any real competition can hardly fail to cause upward movements as pronounced as those which take place in a downward direction. The Tonopah Mining Co., which produces about 250,000 oz. silver per month, will pay a dividend amounting to $250,000 on October 8.

COPPER

Regular quotations have been suspended since the opening of the war, the action being similar to that of the Stock Exchange in suspending quotations on securities in general. The matter is discussed editorially in this issue. We present below the prices at which the large companies have been settling for copper in New York since suspension of quotations, and the usual monthly summaries. The average for August is that at which the A. S. & R. Co. made settlements for copper purchased from July 31 to September 14 inclusive. These prices are, as usual, for electrolytic copper and are stated in cents per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Week ending	
Sept. 3	75.00-85.00	Sept. 17	75.00
" 10	75.00	" 24	75.00
		Oct. 1	55.00

Monthly averages.

St. Louis wires that immediate demands seem satisfied and the market is dull. Ore, basis of 60% metal, is down to $41 per ton. Buyers' orders are easily filled. Exports from New York since August 18, when the movement started, total 11,000 tons.

TIN

Prices in New York, in cents per pound.

Monthly averages.

June	45.10	30.72	Dec.	37.57	....

The month has shown a drop from 38 to 31c. per pound. There has been little demand for the metal. Only 250 tons arrived at New York during the two weeks ended September 25, against 1575 tons in the previous fortnight. This will be felt before long. A decreased production is reported from Nigeria, Bolivia, and the Straits. Tin in London is about £135 per ton.

New York Metal Review

The general dullness of trade continues and all quotations are lower. European war influences have brought about some unusual situations. Copper has been dull for both home and foreign consumption and exports will be further curtailed by Great Britain's desire to keep copper out of Germany. Lead has been without feature except for dullness and declining prices. Spelter, for which a fair demand came from England in August, declined sharply when foreign buying fell off. Tin, which has been arriving heavily from London, is selling lower than it did before the war, and despite the low price and uncertainty as to the future supply, consumers have stayed out of the market to a remarkable degree. Antimony has been dull and prices are considerably nearer a normal basis. Aluminum has declined, partly because of offering of metal from England.

COPPER

Recent events brought about in Europe by the desire of Great Britain to cut off Germany's supply of copper will further curtail exports from the United States. The British government has placed copper on the conditional contraband list, and the metal is to be seized unless it can be shown clearly that its ultimate destination is a neutral country. In line with this policy, the government has taken over the stock which was carried in Rotterdam by the United Metals Selling Co. The warrants which covered this metal in the name of a British corporation, C. S. Henry & Co., were taken by the government, the copper paid for and removed to London. Subsequently the government stated that it would seize copper cargoes en route to Holland and not pay for them unless the copper stored in Rotterdam was sent to London, where it would be paid for, or stored for the consignor until the end of the war. Three Dutch vessels with copper aboard are understood to have been held up already. As a result of this situation, war risk underwriters in New York have stated that they do not care to insure copper shipments to Holland. At the outset of September, a dull market prevailed. Sellers were trying to get higher prices, but there were enough holders willing to let go at 12.37½c. cash, New York, to keep electrolytic at that level. About this time there came into vogue the making of special deals and these comprised what activity there was at the time. Some transactions in spot at 12.25c. cash, were recorded on September 8. In the second week small and scattered lots were all that could be traced as sold, some of them at 12.12½c. cash. From the middle of the month on, sales were a little more numerous, but at lower prices, it being easy to find metal at 11.87½c. cash, New York, equal to 12c. delivered, 30 days. While these sales in the aggregate would be considered but a drop in the bucket in normal times, they were encouraging in that they broke the inactivity which had prevailed. Lake declined also in the month, although it was relatively higher than electrolytic. Prime Lake was quoted September 1 at about 13c., cash, but could be had toward the close of the month at around 12.50c., despite the fact that it had been supported by some good buying by ammunition makers. At no time in September were any London quotations available, as the metal exchanges in that city and in New York remained closed. Exportations to September 22, mostly to Great Britain, totaled 11,897 tons. The August exports amounted to 19,676 tons. The Waterbury average for August was 13c. On September 1, the price of hot-rolled sheet copper was reduced ½c. per pound, making the new base 17½ cents.

LEAD

Throughout September the demand was light. Until about the middle of the month the New York quotation was stationary at 3.87½c. About September 9, the St. Louis price, which had been 3.72½c. weakened to 3.70c. and a few days later dropped to 3.67½c. The New York quotation responded to this decline and became 3.85c., on September 16. The American Smelting & Refining Co., on September 24, reduced its quotation to 3.60c., St. Louis, and 3.75c., New York. In the early part of the month there were some exports, but not enough to offset the slack demand from domestic consumers. London quotations declined steadily, the market being adversely affected by the diverting to England of metal originally consigned to Continental Europe.

SPELTER

Prices pursued a steady downward course in September, although the month opened with a rather good demand from England, some of it coming by way of Canada. It was estimated that about 2500 tons was sent abroad in August. Authorities explained the decline in prices by saying that the advance had been too rapid. The high point was 6.05c., New York, and 5.90c., St. Louis, at the end of August. The higher prices which came with the exports caused the makers of sheet zinc to advance their prices on August 29, 25c. per 100 lb., the new base being $7.50 per 100 lb., less 8% discount, f.o.b. cars, Peru, Illinois. On August 21, the same makers withdrew prices altogether. By September 15, the New York quotation for spelter was 5.45c., and by September 24, 5.30c., with St. Louis correspondingly lower at 5.15c. With the lower prices, inquiry from abroad revived and some buying followed.

TIN

In the last few days of August a moderate business was done, but this tapered off, principally because of the desire of dealers to sell, which frightened consumers off. The figures of the New York Metal Exchange, which appeared on August 31, showing that domestic deliveries in that month had been but 2900 tons, while there was on hand some 1077 tons, both surprised and disappointed the trade. Total deliveries for eight months of this year showed a decrease of 1300 tons as compared with the same time last year. The arrivals in August were 2680 tons and there was afloat at the end of the month 1930 tons. The market lost strength almost constantly in September, a chief cause being the heavy arrivals, some of which were 750 tons on the steamer *Minnehaha*, 435 tons on the *Minnetonka*, 120 tons on the *Celtic*, 850 on the *Menominee*, and 725 tons on the *Minnewaska*. Most of this tin was out of warehouses in London and the arrivals were explained by the fact that America was the chief consuming market and holders abroad sought to realize. When the London stocks are depleted, or nearly so, it remains to be seen just what will ensue, inasmuch as production may be lessened and probably has been already. Only meagre information is coming from the Straits. Another influence which may yet be felt is that of still higher freights and war insurance in view of the activity of German ships in Indian waters. The New York quotation at the beginning of September was 38c. The extent to which consumers held off was remarkable, and by the end of the first week the price was down to 33.75c. for spot metal. Sellers took the course of asking for bids instead of naming their price. By September 15 the quotation was down to 31.35c. From September 9 to 15, consumers continued to feel secure in the knowledge that about 3500 tons would be available for the deliveries of the month. Then there came a flurry in futures, some of which ran ahead to January. The price on September 22 was 31.60c., and on September 24, 31.12½c. The arrivals up to September 22 were 3703 tons, and there was afloat on that date 1165 tons. At the Banca sale held in Amsterdam, September 3, only about 900 tons was sold, the selling limit being 95 florins, equal to about £158, London basis. About 1400 tons was withdrawn from the sale. The Pacific Coast imports in June were 252,030 lb. in the San Francisco district, and 73,241 lb. in the Washington district. The total visible supply August 31, 1914, was 14,452 tons, against 14,167 tons a year ago.

ANTIMONY

Demand was light, and this with the large supply on hand brought the war prices down steadily. Cookson's was quoted September 1 at about 15c., Hallett's at 14 to 15c., and Chinese and Hungarian grades at 12.50 to 14c., while on September 23 the quotations were 11c. for Cookson's, 12c. for Hallett's, and 9 to 10c. for the other grades, these prices being about 1c. below the import cost. In bonded warehouses, September 1, there was 1,190,356 lb., against 3,601,015 lb. September 1, 1913.

ALUMINUM

The only features that appear are dullness and offerings of aluminum from England at 19c., which did not find takers, but served to make prices decline. At the middle of September, 19c. to 19.50c. was quoted for 98 to 99% pure metal. The English aluminum appeared on the 18th and prices dropped to 18.50 to 19c., and by the 24th were down to 18.25 to 18.75 cents.

The Cyanide Situation

Cyanide shipments from Germany to the United States are to be resumed immediately and 1000 tons is believed to be available for transport. An American ship is to be sent to Antwerp to bring back dye-stuffs and cyanide. It will be financed by the men in the dyeing industry and will go under the patronage of the United States government. So much was determined Wednesday at a conference held at Washington, on the invitation of Mr. Bryan as Secretary of State, acting in conjunction with Mr. Redfield, Secretary of Commerce. This conference, as told in our editorial columns, followed an exchange of telegrams between Washington and Berlin over the shortage in cyanide, dye-stuffs, and chemicals in this country resulting from the war. It was attended by about fifty representative men, including Thomas T. Read, our New York editor. A general committee was formed to arrange details, and on that committee the mining men are represented by Carlos Van Law, of the U. S. Smelting, Refining & Mining Co., and Paul Mosolff, of the Roessler & Hasslacher Chemical Co. While the German government has made it a condition that the cyanide is not to be re-exported, it is believed that this will not prevent shipments to Mexico and South American countries, and the State Department has cabled the American ambassador to request that Latin America be included. He has also been instructed to ascertain the form of guarantee demanded. The Roessler & Hasslacher plant at Perth Amboy is running at full capacity, and so far the shortage has been more apparent that real, though stocks have been disappearing rapidly. If necessary this firm will send a ship for the cyanide.

It will be remembered that Roessler & Hasslacher, the principal dealers in America, closed the New Jersey plant when the new tariff law went into effect, and has been depending upon imports entirely. In view of the uncertainty as to the future this firm and others have, naturally, hesitated to plan for extensive manufacturing in the United States to meet the present emergency. The American Cyanamide Co. plans to be in the market by January with American made cyanide. In the meantime that firm refuses to sell cyanamide for metallurgical purposes, as the efficiency of the unconverted material is so low that such sales would probably react to injure the business it is expecting later to build up.

Prices of cyanide have gone up much less than might have been anticipated in view of the shortage. Roessler & Hasslacher has taken care of all regular customers and has done what it could for others. Second-hand lots have been reported bought in various parts of the country at prices ranging from 20 to 30c. per pound, but the regular trade has been at about 15c. The Nevada Mine Operators Association has contracted for the next year's supply at 15¼c., which is only one cent more than the price for the current year.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.

*Extra charge for packing nitric acid for shipment to conform to regulations.

The Roessler & Hasslacher Chemical Co. of New York, in its chemical list of September 16, stated that the excitement of the chemical market has to some extent subsided. Buyers are beginning to realize that their excited rush for goods has only led to unreasonable prices. Some chemicals cannot be supplied for some time to come.

INDUSTRIAL PROGRESS

Combination Pocket Rule and Level

The Lufkin Rule Co. is offering a 2-ft. folding boxwood rule fitted with a spirit level. The three 8-in. rule-sections are each 1 in. wide, $\frac{5}{16}$-in. thick, and united by substantial brass joints. The rule is fully graduated the entire length on both sides, one side inches to eighths, the other side to sixteenths. The spirit level is neatly set into and flush with the upper edge of the middle section of the rule where most convenient for use and securely protected by the two outer sections of the rule, which fold against it on either side when closed for carrying in the pocket. The rule is but 8 in. long when folded, and may be conveniently carried in the pocket. Closing pins especially designed for the purpose hold the sections of the rule in proper alignment, insuring a perfect bearing surface.

Commercial Paragraphs

Sprague conduit boxes and fittings are described in pamphlet 142, issued by the Sprague Electric Works.

The Mark Mfg. Co. is distributing a descriptive booklet covering the methods of making the Mark cold-drawn steel union.

The Chicago Pneumatic Tool Co. is now marketing the Ruby all steel sectional buildings designed for railroad and general engineering purposes.

The Senn Concentrator Co. now has ready an attractive bulletin giving details of the Senn system of concentration without classification and the Senn pan-motion amalgamator.

The Western Electric Co. is distributing a new publication called 'Home Talk,' in which the availability of intercommunicating phones in the home is discussed. Another illustrated folder on 'Profitable Electrical Merchandise' catalogues dealers' helps of various sorts.

'Core Drilling by Contract' is the title of a well printed small booklet issued by the Sullivan Machinery Co., and describing one of the oldest phases of the work of this Company. Sullivan diamond-drills have been used in all parts of the world and the Company has done notable work in contract drilling.

The Cement-Gun Construction Co., of Chicago, announces that it has closed a contract with the Odanah Iron Co. at Hurley, Wisconsin, for lining one of the iron ore mine shafts with gunite, protecting the steel sets against corrosion, and protecting the wood lagging against decay and fire, making the shaft fire and waterproof.

The Wellman-Seaver-Morgan Co. has recently issued an attractive catalogue covering the Hughes mechanical gas-producer made by that firm and largely used by zinc smelters, and a smaller but well illustrated booklet showing ore and coal handling machinery, cranes, hoists, and steel and coke making machinery made by that firm.

'How to Roof Your Buildings Permanently,' is the title of a little pamphlet issued by the H. W. Johns-Manville Co., calling attention to the J-M asbestos roofing which is made of all mineral materials. The great fires at Salem and Paterson have called attention to the necessity of having non-inflammable roofing materials. Indeed at Paterson an ordinance has been passed requiring the use of such material. Since then over 2000 roofs have been covered there with asbestos shingles or asbestos ready roofing.

EVEN the Emperor of Germany had to drop to the bottom of the front page when news of the passage of the Alaska coal-land leasing bill reached the *Cordova Daily Alaskan*.

DYES are mostly reduced from coal-tars, and Germany has led the world in their manufacture. Yet, out of the annual consumption of $25,000,000 of dyestuffs in the United States, the domestic production is about 70 per cent of this total, showing that the chemical industries of the country are not lagging behind.

COPPER producers are much disturbed by the interference of Great Britain with shipments to Holland, and there has been talk, both at Washington and London, of strong protests being made. So far as the copper is for genuine use in Holland there is a clear right to make the shipments; the difficulty lies in assuring that it will not find its way into Germany. In peaceful times there are large shipments through Rotterdam.

TECHNICAL journalism in Germany has its difficulties to face this year, but we are glad to note that interest in the war has not entirely prevented attention to matters of peace and of permanent interest. *Metall und Erz*, for August, reaches us with fewer pages than usual, but including, as always, material of real merit. Among things too good, evidently, to be omitted are reviews of Mr. F. H. Dakin's paper on the Gray Eagle mine, and Mr. James M. Hyde's on the Murex process, published in the *Mining and Scientific Press*. Our cordial sympathy goes out to the editor, Mr. Karl Nugel, and his staff, in these trying times.

MODERN industrial chemistry had its beginnings in the wars of France following the revolution, especially those waged by Napoleon. Cut off from international commerce by the Continental blockade, the nation offered prizes and rewards for the discovery of processes which would make her more self-dependent, and, stimulated by these as well as the compelling force of 'must,' French chemists and engineers made tremendous advances in knowledge that were later adopted and developed by Germany and England, much to their economic advantage. It is too early yet to perceive what effects the present European war will have on international economics, but it is safe to assume that they will be noteworthy.

FURTHER correspondence from Australia, dated September 9, shows that mining generally in the Commonwealth is very dull, principally due to the war. The tendency will be for assessment-paying companies to shut down altogether, and base-metal producers of any description will find it difficult to keep going at all by reason of the suspension of their ore-buying contracts. Broken Hill is working on half time or less. The governments of South Australia and Tasmania, particularly, have made proposals to mining companies in an effort to keep the mines in operation. In general, these are that the governments will advance 50 per cent against the value of production. A somewhat similar arrangement has been made between the Hampden-Cloncurry Copper Company and the Commonwealth Bank. The latter will advance a certain percentage against copper, and the Company has concluded an arrangement with the employees by which they will be paid only half their wages until the copper is sold. There has been a drought in parts of some states, and unless rain falls soon, the harvest will be considerably below that of last season.

MANY lessons can be drawn from the present war in Europe, varying according to the preconceived opinions of the one who draws them. There is a general tendency, apparently, to blame the debacle upon the bad habit of European nations of having kings; more especially the unwisdom of Germany in supporting Wilhelm II as her war lord. Machiavelli once remarked that war ought to be the only study of a prince, who should consider peace only as a breathing time which gives him leisure to contrive and furnishes ability to execute military plans. When it was constantly necessary for peoples to protect themselves by force of arms, this was good logic, but it must be remembered that princes can not fight unless their people are willing to do the fighting. The Servian peasants are certainly quite as willing to fight for what they consider their rights as the Kaiser is to have the Germans fight for what he considers the rights of the Teutons. The advocates of monarchism have at least as good a case in pointing out the inefficiency of a republican form of government. There is a good deal to be said for kings and princes, since many of them work for the advantage of their country as a whole, instead of devoting themselves to petty politics in order to secure their reëlection.

IN taking charge of the Homestake mine in succession to T. J. Grier, Mr. Richard Blackstone has issued a letter to employees in which we note with especial interest that he promises particular attention to safety and purposes to use his best endeavors "to promote the things that make for a happy and contented people." This frank acceptance of the social responsibility of a mine manager is in accord with the traditions at Lead and the best thought of the times.

THE NORTH STAR, GRASS VALLEY

In this issue we are enabled to publish an interesting review of the operations of a famous old mine: the North Star, at Grass Valley. The account is written by Mr. William Hague, a director of the company and son of the late James D. Hague, to whom this enterprise and the American mining industry in general owes a debt it is a pleasure to acknowledge; for, among other services, was he not the earliest sponsor, if not discoverer, of the Calumet & Hecla? With Mr. William Hague in the authorship of this valuable contribution to the records of Californian mining enterprise is Mr. W. D. Pagan, the faithful and efficient secretary of the North Star Mines Company. It is rarely that technical literature is enriched by testimony so satisfactory as to the operations of an individual enterprise. The North Star is a remarkable example of the rewards that follow upon sagacity, energy, and sane optimism. More than once in its history, and especially in 1875, the end seemed plainly in sight, but by dint of further exploratory work, intelligently planned and economically performed, the enterprise was put on its feet again, and since then there has been no looking backward. Besides the Hagues, father and son, we may mention the two generations of Foote, Mr. Arthur De W. Foote, who was resident superintendent from 1896, and is now succeeded by his son, Mr. Arthur B. Foote. The average man outlives the average gold mine, but the North Star is characterized by unusual persistence, and will, we hope, test the vital powers of the present generation.

The North Star vein is in a fracture traversing diabase; the walls are well defined, three to four feet apart, the space between being occupied by a variable thickness of quartz, together with country rock, which is crushed and impregnated with pyrite. The ore consists predominantly of quartz, containing 2½ per cent iron pyrite, a little galena, and native gold. The vein dips flatly, at 23 degrees, so that the maximum depth of 5390 feet represents a vertical distance of a little more than 2000 feet. The most productive level has been the 3700. By dividing the workings into an upper and lower portion, in accord with the actual history of the undertaking, it is shown that the profit per ton has been practically the same for the two physical and chronological divisions, being $5.40 and $5.48 respectively. This equality of result is due to the fact that the declining yield per ton has been exactly compensated by a diminution of cost, the yield of $18.30 and $11.87, respectively, per ton being subject to a cost of $12.90 and $6.38, respectively. This, of course, is a highly creditable performance and indicates consistent improvement in the technical operations. As to the application of these figures on the interesting question of persistence in depth, that is, the enrichment, impoverishment, or uniformity of the ore as the mine workings gain in distance from the surface, it is not easy to generalize. The profit has been maintained practically without change, but this, as we have seen, does not mean that the yield of the ore has been unvarying; moreover, the yield is not the same thing as the gold content. In the one case the cost and in the other the extraction are crucial factors. What amount of sorting has been done? In other words, has the grade benefited or suffered by selection?

In most mining operations, the separation of waste from ore, of wall-rock from vein-filling, is an important operation. This feature is occasionally overlooked by those that sample mines; they make insufficient allowance for the relative cleanness of sampling; so that mines usually yield a bigger tonnage at a lower average metal content than the reports of engineers have predicted. Between the 3000 and the 4000-ft. levels, I am informed by Mr. Hague, the vein is divided into more stringers than in the upper part of the mine, so that the ore sent to the mill is not as clean. In the upper workings the vein, and the quartz of which it is mainly composed, was narrower, so that the yield per ton has declined, but the yield per unit-width has increased. Moreover, the deeper operations gain from a higher extraction in the mill. Joshua E. Clayton, in the report made in 1869, estimated the yield to be $25 and the loss in milling at $3 to $4 per ton, indicating an extraction of 85 per cent. In those days the sampling of the ore and the measurements of the loss in tailing usually erred a little on the pleasant side, so that we are justified in estimating an extraction slightly less than 85 per cent. In the early days of the mine the milling was crude, so that, despite the simple character of the ore, the metallurgical work was even less effective. In 1913 the metallurgical treatment, by aid of cyanidation and filter-pressing, had reached so high a state of efficiency as to extract 97½ per cent of the gold in the ore. This increase of extraction, as between the upper and lower workings, equal to about 15 per cent, is a factor in contributing to the maintenance of profit, despite a decrease in the yield of gold per ton of ore milled. However, it would appear that the maintenance of the profit at a nearly fixed amount per ton is due mainly to the decrease in cost—from $12.90 to $6.38—so that, on the evidence, we must conclude that the question of richness is to be answered by saying that the ore is poorer in depth, although the impoverishment, from an economic standpoint, is compensated by the joint effect of three factors: the increased width of ore, the lessened cost of exploitation, and the notably improved metallurgical treatment.

At the end of 1913 the North Star workings were 5850 feet deep on the dip, or 2200 feet vertically. Sinking is to be continued to 6300 feet, and levels will be extended at 5700 and 6000 feet. While the length of the shaft on the incline is impressive, the North Star cannot be regarded as a deep mine, in the modern sense, nor from a geological point of view. Whatever may be the chemical and physical conditions that modify the precipitation and concentration of gold in a vein, it may be assumed that any change is measurable in vertical depth, not along the dip of the vein, unless that should involve a change of angle. As the North Star vein is traversing a crystalline rock and is only about 2200 feet deep, the chances of further persistence on the part of the main orebody are still good, more particularly in view of the good behavior of the Empire vein, in the vicinity. But the persistence already proved in the cases of these two famous mines at Grass Valley must be considered exceptional, in the light, for example, of the half-a-dozen other local ventures made by the North Star company itself, as recorded on another page. Such persistence as that of the North Star orebody is unusual, and whether it may be maintained further can be ascertained only by digging. In any event, the North Star will have furnished a splendid example of intelligent mining and skillful enterprise.

T. A. Rickard.

FLOTATION OF THE ELM ORLU ORES

Adoption of the Minerals Separation froth-flotation treatment for Elm Orlu ores attracted much attention when first announced by the *Mining and Scientific Press* in May 1913. Interest was all the more keen since it was known that the engineers of Mr. W. A. Clark's staff had carried on exhaustive tests through nearly a year and had tried virtually all competing processes. The mill went into commission last June and has now settled down to regular work. Designed to handle 300 tons per 24 hours, it is regularly exceeding that capacity, treating in fact about 450 tons per day. The recovery effected has been equally satisfactory, the total ranging from 94 to 98 per cent, with the average of approximately 96. The flotation department, handling as it does the leaner and usually less easily saved mineral, falls a little below this total. The daily figures range from 85 to 97 per cent, the average falling perhaps near 94.

The ore from the Elm Orlu mine is a mixture of zinc, lead, and copper sulphides in a silicious gangue. About 75% of the metal content is freed by crushing to 40 mesh, but it is necessary to grind to 150 mesh to free the remainder. The ore assays between 17 and 22 per cent zinc, with an average of a trifle above 19. It was to recover this zinc, especially, that flotation was adopted. The mill in which the ore is treated belongs to the Timber Butte Milling Company, of which the superintendent is Mr. W. N. Rossberg. He, with Mr. E. H. Nutter, of the Minerals Separation staff, is responsible for the flow-sheet and general arrangement of the mill. Minerals Separation, Limited, is directly represented in Montana by Mr. G. A. Chapman, at Anaconda, and Mr. T. M. Owen at the Timber Butte mill. Mr. Joseph Pyle is the general representative in Montana of Mr. W. A. Clark, main owner of both mine and mill.

The mill includes both wet-concentration and flotation departments. The ore as received from the mine is crushed by means of a rock-breaker and rolls, screened with impact screens, and delivered to Wilfley tables for a rough separation. Some clean zinc is taken off here, and a zinc-iron concentrate is made which is sent to a jigging and table department, being joined at the elevator to the classifier by a lead product derived from the tailing from the roughing Wilfley tables through regrinding in a Hardinge mill and treatment on James tables. A second zinc product is taken from the James tables, and a tailing which by-passes the jig and second set of Wilfleys, going direct to the flotation department. Overflow from the classifier feeding the jig and tables mentioned goes to Dorr settlers later to be noted. The flotation department includes both primary and secondary flotation machines, with Hardinge mills for regrinding, Akins classifiers ahead of the flotation machines, and an Avoca below. The first flotation produces a concentrate for further treatment and a tailing which is split in Akins classifiers into a sand (returned to the system for regrinding) and a slime which goes, through Dorr settlers, to waste. It is to be noted that all material, save the course concentrate, is crushed to 150 mesh and treated by flotation. The secondary flotation produces a middling (returned for regrinding) and a concentrate which goes through the Avoca classifier and settling boxes to James tables for cleaning. The tailing and middling produced are returned to the system in appropriate places for regrinding, while the lead and zinc concentrates go to bins. The fine concentrate from the overflow from classifiers is thickened in Dorr thickeners and filtered in a Kelley press. Water is, as usual, returned to the circuit from various appropriate points. The only point at which waste is eliminated from the mill is through the Dorr settlers below the primary flotation.

The success of the system adopted has been marked. Starting with an ore containing 19 per cent plus of zinc, a final mill tailing is made assaying 0.7 to 2 and averaging about 1⅓ per cent. The concentrate delivered to the bin from the flotation department assays about 53 per cent zinc, 4.2 iron, and 3 to 4 insoluble. Concentrate from tables prior to flotation assays about 48 per cent zinc, 8 per cent iron, and 4½ per cent insoluble. The lead-iron concentrate ranges from 18 to 28 per cent zinc, 18 to 22 iron, and 10 to 35 lead. The jig concentrate assays 40 to 48 per cent zinc, 8 to 12 per cent iron, and 3 to 4 insoluble. For one period of six days the total mill recovery averaged 95.7 per cent. For the same period the average recovery by flotation, from the leaner ore, was 93.7 per cent. In treating nearly 11,000 tons, 24.6 per cent of the zinc was saved in the coarse

concentrate and 69.4 in the fine. In the lead-iron concentrate 0.6 per cent of the zinc was lost, while 5.1 went into the tailing, and 0.3 per cent was unaccounted for. We extend congratulations upon these excellent results to the engineers concerned.

A MAN AND HIS JOB

The natural effect of the great growth of industrialism during the past half century has been a corresponding increase in the complexity of its structure. Long ago the frequent lack of adjustment between the capabilities of a man and the requirements of his situation was so evident as to give rise to the expressive phrase of 'a square peg in a round hole.' Nowadays the characteristics of men and the demands of work have become so varied that, to preserve the simile, we now have triangular, octagonal, elliptical, or other forms of pegs, and an equal variety of holes. The chances that a square peg will find its way into a square hole are even, the chances that a triangular peg will encounter a triangular hole out of all the variety of forms are decidedly small. In other words, it is now much less likely than ever before that a man will be perfectly adapted to the work he is called on to perform. It is only of recent years, though, that this acute problem of making sure that the man and the job fit each other has received any careful attention. Mr. Herman Schneider, dean of the College of Engineering of the University of Cincinnati, who has had unusual facilities for studying the characteristics of young men averaging 20 years of age, as exhibited both in classrooms and workshops, has recently made an interesting analysis of these characteristics and their effect on the work which the individual is capable of doing.

Unless a man gets, from doing his work, mental and physical development and discipline, some measure of satisfaction, and a decent living he can never be a really efficient workman. Until recently inquiry has rarely concerned itself with other than the third of these, but the importance of the other two is obvious. A manager who is particular as to whether his workmen use a round pointed or square ended shovel will often exhibit indifference as to whether the man using the shovel is of the requisite strength to do such work efficiently. A 130-pound man should not be put at work which requires heavy lifting, nor is a 225-pound man employed to best advantage at bookkeeping. Similarly, some men are skillful with their fingers while others are skillful with their heads: the one would be a good draftsman for routine work and the other for designing. Some men prefer a steady routine, others are driven to distraction by the monotony of fixed tasks; thus of two such carpenters, the one would do better on steady shop work and the other on odd jobs. Some men like to be indoors, others are restless except in the open; some like to work underground, others prefer surface work. In such cases the man only does his best work when he is in the environment which he prefers.

More important than these characteristics is the tendency of some men to assume responsibility and of others to evade it. The best workman rarely makes the best boss, and it is one of the weaknesses of the merit system that it frequently promotes into a position of responsibility a steady-going man who is really a brake on the department of which he has charge. It is likewise necessary to distinguish between the man of originality and the one of constructive ability; the one can imagine some new process or method of procedure, the other can work out the details of successfully performing it. One man may deal only in sketchy outlines, the other concern himself with detail; or one man may be interested only in big scale work like building a railroad, while the other is happiest working over niceties of adjustment, as in watch repairing. Again it may be noticed that one man continues unchanged no matter what his environment, another instantly adapts himself to the circumstances of the moment; one would be a success as a cashier, the other as a salesman. The natural tendency of some men is to think carefully before doing anything; other men act first and think afterward, and in business life this latter characteristic is the least useful of all. In certain occupations a keen sense of color or musical pitch may be extremely useful and its absence a detriment. Some men are naturally accurate; others seem naturally inaccurate, and this observation may apply either to their mental processes or to their manual skill. Often indeed a man who is mentally inaccurate may display surprising skill with his hands. Another mental characteristic is that of concentration; the mental energies of one man are discharged like a shotgun, of another like a rifle. The mental energies of some act slowly, like black powder, of others instantaneously, like dynamite. The hoisting engineer must be able to think and act quickly, but if the mine geologist is slow in formulating his ideas they are the more apt to be right. Finally, some men have staying qualities, others give way under continued strain, just as the man who makes the best showing under favorable circumstances often goes to pieces under the pressure of adversity.

Superimposed on all these varying characteristics is the variation in the weight which each individual places on the relative value of the three rewards of work which we mentioned in beginning. Some men are ambitious to increase their powers and care little about whether their work is pleasant, or whether the financial return for it is adequate. Others like to be comfortable, and having found a satisfactory job want to stick to it. Others are keen to make money and embrace every opportunity to increase their earnings. Thus each man presents himself as a complex bundle of emotions, tendencies, and capabilities. In picking men for the positions under his direction a manager needs to consider all these factors, if he hopes to secure the best results. The old fashioned conservative method of management in which a faithful employee is steadily promoted until he finally reaches the highest position, is obviously a bad method, for it successively places a peg in each hole, only one of which it really fits.

As War Looks in London*

By T. A. RICKARD

A mining man just arrived from Turkey says that the *Goeben* affair has hurt German prestige. This splendid warship was taken around the Mediterranean ports as an exhibit of Germany's latest naval unit. She was shown proudly to the Turks, who were impressed. Now she is interned, having done nothing in the fighting way; so the people at Constantinople make disparaging remarks. But the Turks feel bitterly over England's annexation of the warship and destroyer that were in course of completion for Turkey in British shipyards. This is in accord with international custom, but in this case it hurt intensely because the cost of that warship had been raised by public subscription in Turkey and it was an object of patriotic pride. The money obtained by the compulsory sale will not go to the subscribers, but to a government department, so that it will have failed to achieve its immediate purpose.

The Press Bureau has issued a contradiction of the rumors concerning the Russian contingents from Archangel. The growth of this myth is astonishing. Even now I find as much difficulty in crediting the denial as the affirmation. People claim to have seen trainlonds of Russians coming from the north of Scotland to our southeastern ports: they saw them at the London terminal stations; they knew shipping firms that had transported them; indeed a mining engineer called Champion said that he came with 2500 of them on a ship from the White Sea; and so forth. The explanation must be that the war stimulated the study of maps and thus made manifest the fact that oversea communication was possible from Russia to France without passing through the Baltic; then it was known that a good many English and Americans had come from Russia by way of Archangel to Bergen (Norway) and then to Leith (Scotland); it was obvious that Russian soldiers might be transported along the same route. From the question of why not do so to the idea that it had been done there was only a small gap across which the imagination skipped lightly. Moreover, the Russian government notified its nationals in foreign countries that they might enlist with the Allies, and the actual enlistment of some of these Russian refugees may have given further color to the yarn. Even now, many refuse to believe the contradiction and point to the Press Bureau's statement as equivocal. We shall see. Meanwhile, I hope—and therefore am inclined to believe—that a body of troops will be found coming to the reinforcement of the Allies from the northwest of France. Where are the British troops from India, and why should a part of the Paris garrison not be available in the culminating effort to rout the invading armies?

London, September 16.

Last night I went to hear Winston Churchill. Although I had a ticket and went an hour before the proceedings began, the crowd was so big that the police had to come in force in order to prevent a dangerous crush. As it was, I obtained a seat in the upper gallery, but that was all right, for the place—the Opera House, on Kingsway, built by Hammerstein of New York—has good acoustics. It was full to the limit with a serious and intensely patriotic assemblage. The affair had been organized by the two leading political clubs, the National Liberal and the Constitutional, representing the two big parties; and to make it even more national a Labor representative was one of the three speakers, namely, Churchill, a Liberal, F. E. Smith, a Conservative, and Will Crooks, a Laborite. As Churchill entered he received a wonderful demonstration of good will. Then the band played the national anthems of the various Allies: first the gay 'La Brabanconne' of the Belgians, then the sombre Servian and the solemn Russian anthems; the Japanese anthem has the deep chords that characterize the tragic portion of Puccini's 'Madame Butterfly'; finally the 'Marseillaise,' which was vigorously supported by the audience—by note more than by libretto. When Churchill rose to speak there was another demonstration, and in the effort to express their feelings the thousands before him sang "For he's a jolly good fellow," with cheers. Our inability to express emotion save in a conventional way was curiously illustrated, but when you sing with intense vigor in war-time that a man is a jolly good fellow, you mean more than meets the eye in such homely words. The two succeeding speakers received similar musical honors. Our Winston—to distinguish him from yours—is not an orator in the ordinary sense; he lisps; hence he fails to enunciate perfectly; his person is not remarkable save for a fine brow; he has not the gesture of a great speaker; but—and the 'but' is everything—he is a man of powerful intellect and speaks with all the resources of a big mind. What he said, more than how he said it; what he had done, more than what he looked; that was what carried the audience. He spoke first of the improved military position in France, but warned us that the war would be "long and sombre," and needing our united determination "to plough our British way through obstacles of all kinds, and continue to the end of the furrow, whatever the toil and suffering may be." Turning to the navy, he spoke cheerfully. We have "swept German commerce from the seas." Again, "We have searched the so-called German ocean without discovering the German flag." It was reported to him that the health of the sailors of our fleet "has been much better since the declaration of war than it was in time of peace." Another hit that aroused enthusiasm was a reference to that dispensation of Providence whereby "the nose of the bulldog has been

*In this series of war letters, the *Press* will print extracts from Mr. Rickard's personal letters from London, believing that an account of the war as seen by a mining man in that great centre will be of interest to mining men everywhere. Mr. Rickard is an Englishman who was born in Italy, passed his early boyhood in Russia, managed mines in France and Australia, and lived in the United States more than twenty years. His sympathies are naturally with the Allies.

slanted backwards, so that he can breathe with comfort without letting go." Turning to recruiting, he asserted that a million men must be placed, and maintained, on the continent if we meant to bring the war to its proper conclusion. He made an appeal for conducting the war decently, so that when all is done it may be said "They fought like gentlemen." (Loud cheers.) Then came the part of his speech I liked best, for it was statesmanlike. When the war was over, said he, let us not make the same sort of mistake as Germany did when she had France prostrate in 1870. Let us keep before us the principle of nationality. (Round after round of applause.) "Not the conquest and subjugation of any great community or any strong race of men, but the setting free of those races which have been subjugated and conquered, and if doubt arises about disputed areas of country, we should try to settle their ultimate destinations in the reconstruction of Europe with a fair regard to the wishes and feelings of the peoples who live in those countries." He was followed by F. E. Smith, a brilliant advocate, now the head of the Press Bureau. Smith is a belligerent politician, and bitter partisan, but in his first words he acknowledged that however much he may have disagreed with Churchill in the late past he had never had the slightest doubt that he was "a great and patriotic Englishman." All the bitterness of political strife has vanished, all the old controversies are dead, we are a united nation. His last point was good: that while he had always advocated compulsory national service, he hoped, now that we found ourselves at war on a voluntary basis, we would "go through it, with whatever forces may be required, as a volunteer nation, and by so doing afford our German critics the supreme proof of our decadence," that decadence of which they had talked so much. Our aim was to extort from this welter of bloodshed "the hope of a more permanent peace, and in the end convincing the world that a proud people may passionately love peace and yet be fit for war." Will Crooks, the Labor representative, was well received. We were fighting for home and liberty—the home and liberty of the whole world. He called it 'ome, but I thought to myself, after all, 'ome means even more than home, for those that say it that way are even deprived of an h, or seriously, that the home of the plain working man means more to him than the mansion of the rich. Where, said Crooks, would the Empire be but for the parish-pump and all the little centres of living that it connoted? The Empire was great because in every corner of the earth plain people could live under the Flag in liberty. Then came the resolution, which is worthy of quotation, although resolutions submitted to public meetings are usually fuller of sound than meaning. This one is tense with significance, for it states the purpose of this war in terms as terse as they are truthful. Here it is: "That this meeting of the citizens of London, profoundly believing that we are fighting in a just cause, for the vindication of the rights of small states and the public law of Europe, pledges itself unswervingly to support the Prime Minister's appeal to the Nation, and all measures necessary for the prosecution of the war to a victorious conclusion, whereby alone the lasting peace of Europe can be assured."

And as I copy these words I hear the patter of horses' hoofs on the road, marking the departure of another detachment of the Scots Greys, the regiment whose cavalry smashed the Imperial Guards of Napoleon at Waterloo, and helped to end the arrogant militarism that tyrannized Europe one hundred years ago. May they hurl themselves into the battle with the same old courage and for the same old cause: the liberty of the people.

London, September 12.

You may have heard how nearly the *Tennessee* fell a victim to a mine. She went to Flushing to perform her mission in aid of American refugees, and, in order to maintain her wireless service, she kept outside the 3-mile limit. D. M. Riordan, of New York, who was specially engaged by the Secretary of the Navy to take charge of the business end of the expedition, went ashore in a Dutch boat, together with other American officials. On returning, they had re-embarked, and were under way, leaving the Dutch boat in their wake, when she came in contact with a mine and was destroyed. If that mine had struck the *Tennessee,* there would have been an explosion of another kind that would have echoed round the word! It might have proved a repetition of "Remember the Maine." A great chapter in history was skipped.

A man named William Clark, from Bootle, near Liverpool, went through the South African war unhurt and then was a fireman on the *Titanic* when she went down. As if that were not enough coquetting with Death, he was on the *Empress of Ireland* when she was sunk: and again escaped unseathed. He has now re-joined the army. Surely he is the man destined to capture the Kaiser or to blow up Krupp's factory—the two feats most to be applauded at this time.

London, September 29.

AS SEEN IN FRANCE

Below is an extract from a letter of an American artist living in northern France. "I think we are not, at the most, 50 miles from the front now and very great possibilities of its enveloping us within a very short period of time. If that comes to pass, we must get out of range as best and as fast as we can as thousands from farther north and east are doing today. Passing here in a continuous stream are women and children, many destitute and on foot carrying their pitiful little bundles and begging for food. We are doing our best to help them until in our turn we have perhaps to do the same thing. Very fortunately for us I was able to get a check for $500 on New York cashed in Paris the other day, so have some funds to carry us over until things change. Otherwise we would have had to ask charity too, for by the law of mortatorium our bank account in a French bank was unavailable except at the rate of 5% per month."

The North Star Mine, Grass Valley

By WILLIAM HAGUE and W. D. PAGAN

The North Star mine, the largest producer of the group of properties owned by the North Star Mines Co., was discovered in 1851, and with the exception of ten years between 1874 and 1884 has been in continuous operation ever since. The mine has thus a career of over fifty years behind it, and a brief history of its varying fortunes, including some account of the other adjoining properties now under the same ownership, may be valuable as a matter of record as well as of interest to stockholders.

Early History

These properties are situated about a mile and a half south of the city of Grass Valley, in Nevada county, California. Grass Valley, about 2400 ft. above sea-level, is connected by a branch railway, 16 miles long, with the Southern Pacific railroad at Colfax, 144 miles northeast of San Francisco. The terminus of the local railway is at Nevada City, five miles beyond Grass Valley.

The first discovery of gold in California, at least of real historical importance, was made at Coloma, in Eldorado county, in 1848, by James W. Marshall, who later in the same year found the metal on Deer creek, within the limits of what is now Nevada City. Since that time, California has produced more than $1,500,000,000 worth of gold, of which the quartz mines of Grass Valley and Nevada City have contributed about $110,000,000, and the properties now owned by the North Star Mines Co. (not including the Champion), $25,000,000 to $27,000,000.

The discovery of what is now known as the North Star vein was made by two Frenchmen, the Lavance brothers, while sluicing on the side of the hill where the North Star mill now stands, probably in the fall of 1851; for on November 10 they recorded the first location. The vein was first known as the French lead, and the hill on which it outcropped was called Lafayette hill. In the next few days nine other Frenchmen recorded their locations, each claim being one hundred feet square. These Frenchmen evidently decided to form a combination in restraint of 'jumping,' as the Helvetia & Lafayette Gold Mining Co. was formed by some of them in the course of a year or two to work their claims. The discovery attracted many prospectors, and the records show several hundred locations made in the next few months, many of which were 'jumped' at various times. Just east of Lafayette hill some of the later owners located the eastern extension of the North Star vein, upon what they called Weimer hill. Whether or not this Teutonic name was chosen to irritate the Frenchmen on Lafayette hill, does not appear. The locations forming the Helvetia & Lafayette property took 480 ft. along the strike of the vein and appear to have been about where the present North Star shaft-house stands. East of the Helvetia & Lafayette for 800 ft. came another consolidated group of claims known as the Independence, and for 800 ft. east of this came the White Rock group. A group of claims known as the North Star was located some time prior to 1860 on a split from the vein in the hanging wall over the Helvetia & Lafayette ground.

In 1858 the Helvetia & Lafayette came to grief and was sold by the sheriff to Edward McLaughlin to satisfy judgments for $8000. In February 1860 McLaughlin sold the property to J. C. Pascoe, Edward Coleman, and others, for $15,000. These men also owned the North Star group, and in 1861 they formed a mining partnership known as the North Star Quartz Mining Co. Between 1861 and 1866 many of the other claims in the neighborhood were bought by this Company. Bean's Directory states that the net profits for the five years ending 1866 were $500,000, or at the rate of $100,000 per annum. The tonnage milled was probably about 7000, and the total outlay about $150,000 per annum. This would mean that the mine produced, say, 35,000 tons, with a gross yield of $1,250,000 during this period—probably too high an estimate. The gross production, therefore, for the five years is assumed at $1,000,000. It is also estimated that for the ten years previous to 1861 the vein produced 25,000 tons, yielding $500,000, making a total from 1851 to 1866 of $1,500,000 from ore averaging $25 per ton.

In 1867 the North Star Gold Mining Co. was incorporated, with a capitalization of $1,000,000. This new Company purchased from the North Star co-partnership the Helvetia & Lafayette, the North Star, the Independence, and other claims on the Weimer and Lafayette hills. These various claims were consolidated as the North Star claim, under United States patent issued on August 11, 1875.

In 1875 the mine was closed down, being then about 1200 ft. deep on the incline, a decrease in the yield of the lode making its operation unprofitable. From a report by Joshua E. Clayton made in 1869, and from figures given in the 'Mineral Resources West of the Rocky Mountains' for the years 1871, 1872, 1873, and 1874, it is estimated that the mine produced between July 1867 and September 1873 some 50,000 tons, yielding $1,125,000 in round numbers. The expenses were in the neighborhood of $150,000 per annum, which would indicate a profit of $225,000.

A New Start

In May 1884 the North Star Mining Co. was incorporated, with a capitalization of $1,000,000, to take over the property of the North Star Gold Mining Co., and the mine was reopened and the shaft sunk. Since that

date the vein has produced continuously, though for several years prior to 1902 in a very limited way.

Between 1884 and 1894 the North Star shaft was sunk to the 2300-ft. level, and the ore-shoot that had been followed from the surface, and which lay for the most part west of the shaft, was stoped. Very rich rock was found on the 1800-ft. level near a displacement in the vein caused by a 'crossing.' Good ore was also extracted between 1900 and 2100 ft., which made the yield in 1893 over $31 per ton. This ore-shoot produced in round numbers 250,000 tons yielding $5,250,000. At the 2300-ft. level, however, the quartz ceased, and the vein below it became small and 'tight.'

The Vertical Shaft

Although the outlook at the time was not particularly encouraging, it was decided to sink a vertical shaft to intersect the vein at a depth of 4000 ft. on the dip, and work was commenced in 1897. To provide funds for the purchase of additional claims and more extensive explorations, the capital of the North Star Mining Co. was increased in 1894 from $1,000,000 to $2,000,000; and in April 1899 the North Star Mines Co. was incorporated under the laws of New Jersey, with an issued capital of $2,500,000, to take over the property of the North Star Mining Co. and to furnish the funds required for the expensive undertaking of sinking the new shaft.

Exploration to the eastward had hitherto disclosed a barren vein, and had never been pushed far. In 1900, after certain adjoining claims had been purchased, the 500-ft. level was extended eastward, and after being driven some distance passed through the top of a narrow shoot of rich ore. Surface indications overhead had never encouraged prospecting in this direction before. Exploration was hastened on the 1100 and 1900 east, because of this discovery, and the downward extension of the shoot was discovered. The ore from this was rich, from one place 18,000 tons yielding an average of $37.50 per ton. Operations in this orebody and in one a few hundred feet east of it, between and including the 1100 and 2700-ft. levels, continued until 1911, and resulted in a total production of about 182,000 tons.

On March 31, 1901, the vertical shaft begun in 1897 cut the North Star vein at a vertical depth of 1630 ft., or a depth of about 4000 ft. on the dip of the vein. Development work was for some time hindered by the heavy flow of water and by the necessary equipment of the shaft for more extensive operations. Levels were, however, started east and west, and a rise was begun to connect with the bottom of the incline-shaft. The rise was carried up on the vein and finally connected with the incline-shaft on November 22, 1903.

Results in Depth

Subsequent developments have proved that the vein in the deep levels is wider and more extensive than in the upper mine, although the yield per ton is lower. The most productive level has been the 3700, which will probably, first and last, yield over 200,000 tons, or four-fifths as much as the ore-shoot that the mine was opened on. This level also has the distinction of having furnished a pocket of high-grade ore, worth $40,000, which was brought to the surface in some 20 candle-boxes.

Since March 1901, to the end of 1912, successful development and profitable operation of the ground worked through the vertical shaft have continued, with levels extended to various lengths, east and west from the shaft, at 3000, 3400, 3700, 3900, 4000, 4400, 4700, 5000, and 5300 ft. In 1906 the shaft, following the vein on the incline, was continued below the 4000-ft. level and had reached a depth of 5390 ft., when work was temporarily suspended in June 1908. The development work in the lower mine amounted, in all, to the end of 1912, to 43,192 feet.

The tonnage of ore hoisted from the shaft and deep levels, up to the end of 1912, was as follows:

Shaft	19,020	4400	11,743
3000	96,544	4700	15,742
3400	181,731	5000	12,087
3700	191,808	5300	4,373
3900	8,577		
4000	93,403	Total	635,028

Of the above tonnage hoisted from the deep levels, 626,509 tons was crushed, of a gross value of $7,496,499.73, compared with an estimated yield from the surface to, and including, the 2700-ft. level of 438,273 tons, of a gross value of $8,019,016, making a total production for the North Star mine to the end of 1912 of 1,064,782 tons, of a gross value of $15,515,515.

The enterprise as now conducted has been practically continuous since 1884, and precise figures can therefore be given for a period of over 28 years. The following comparison may be made between the results of the operation of the upper and lower levels of the mine:

Upper Mine Operations, to and Including 2700-ft. (1200 ft. Vertical) Level

From 1851 to end of 1913.
(Operation of upper levels ceased in 1911).

Production (438,000 tons at $18.308)	$8,019,000.00*
Operating and development expenses (per ton $12.90)	5,650,000.00†
Profit (per ton $5.408)	$2,369,000.00

Vertical Shaft Operations, 3000 to 5300-ft. (2000 ft. Vertical) Level

From 1901 to end of 1913.

Production (732,599 tons at $11.871)	$8,696,596.15
Operating and development expenses (per ton $6.383)	4,676,371.43
Profit (per ton $5.488)	$4,020,224.72

Total North Star Vein (Surface to 5300-ft. Level)

From 1851 to end of 1913.

Production (1,170,000 tons at $14.286)	$16,715,000.00
Operating and development expenses (per ton $8.825)	10,326,000.00
Profit (per ton $5.461)	$ 6,389,000.00

*Includes estimate of 108,000 tons prior to 1884, yielding $2,625,000.

†Includes estimate of expenses prior to 1884, $2,000,000.

Milling

The first mill of the North Star Mining Co. was equipped with 30 stamps. It went into operation in April 1887. Ten additional stamps were added in December 1888. The productive capacity of the mine, greatly increased by the opening of the deep levels through the vertical shaft, justified an addition to the milling equipment, and early in 1903 grading for a new 40-stamp mill was begun. The mill was completed and started crushing in August 1904. The efficiency of the old mill has also been increased and the crushing capacity of the 80 stamps is now about 8500 tons per month.

As an illustration of the increased productivity of the mines and crushing capacity of the mills, it may be said that the tonnage milled during the 9 years ended December 31, 1912, was two and three-quarter times that for the previous 20 years. In 1904 the construction of cyanide plants to treat the tailings from the two mills was begun. This equipment has been enlarged and improved from time to time, at a total cost to the end of 1912 of $99,529. In 1907, at the Central plant, the cyanide process was successfully applied to the treatment of the sulphide product of the mills, yielding better economic results than were previously obtained by chlorination or smelting. The process of recovery, in fact, has been so perfected that the mill-losses which, according to Clayton, amounted in 1869 to $3 or $4 per ton, and which between 1884 and 1900 were probably not less than $1.50 per ton, have now been reduced to about 26c. per ton.

Production and Depth

The tables already given set forth the production of the North Star vein and show a decline in the yield per ton with increased depth; but to offset this it appears that the yield per square foot (horizontal)[1] mined has increased. This may be explained by the fact that in the upper portion of the mine, above the 2700 level, both the vein and the quartz were narrower, with fewer stringers than below, although definite figures on this point cannot now be given. To lose now as few stringers as possible, much waste is unavoidably sent to the mill, thereby reducing the yield per ton from what it would be if only clean quartz were treated. This course seems to be justified by the result, as a greater total yield for the vein as a whole is made available. The North Star vein is now exhausted, so far as is known, above the 3000-ft. level. The total area mined above this level is in round numbers 2,100,000 sq. ft. of a total of 6,000,000 sq. ft. prospected, or, in other words, 35% of the exploited ground has proved profitable.

In the report made by Clayton in 1869 he stated that with good management there was no reason why the cost, at that time of $16 to $20 per ton, should not be reduced to $12 per ton. For the five-year period ended with 1892 the cost, including improvements, was $12.35 per ton. Since then the cost has been dropping until now it is about $5.25 per ton mined. The profit per ton has remained nearly constant since 1884.

[1]That is, the area of the stope projected on a horizontal plane and measured on the map by a planimeter. Owing to the flatness of the vein, the horizontal projection is used instead of the vertical projection. The yield per square foot of vein-area would be about 10% less.

Other Ventures

The North Star companies have devoted considerable effort and money to the exploration of neighboring properties. In 1894 the North Star Mining Co. effected the purchase of the Massachusetts Hill property. The claims comprising this were located prior to 1861, and produced remarkably during the first years after discovery. High-grade ore outcropped on the surface, and for several years the part of the vein worked by William Watt yielded at the rate of $80 per ton. From the areas known to be stoped, it is estimated that this vein prior to 1896 produced 125,000 tons, yielding $4,000,000 to $5,000,000; the orebody upon which the locations were made went down for 600 ft. or so, when the vein became barren, causing the owners to cease operations. Tragedy as well as prosperity befell some of the early owners. Michael Brennan, in sinking a vertical shaft to cut the Massachusetts Hill vein, expended all his own, as well as his partners', money, without reaching the desired goal. One Sunday morning in a fit of despair he killed his wife and his three children and then committed suicide. His creditors took over the prospect and after sinking the shaft a very few feet deeper disclosed the vein that Brennan had just failed to reach.

The mine was re-opened in 1896 by the North Star Mining Co. The shaft was sunk and near the 1200 level another orebody was cut, which yielded $1,000,000 from 68,000 tons. The shaft was continued to the 1800-ft. level, and some driving was done, but no more ore was found. The ore-shoots in this mine seem to be irregular and uncertain; the proportion of profitable ground, when the work on the vein farther north at the Gold Hill, is included, is about 20% of the vein-area opened. The mine was closed down in 1901. The profit from this operation, all told, was not a large one, but the enterprise kept the Company actively engaged during the lean interval encountered about this time in the North Star vein.

New York Hill

In 1894 the New York Hill property was purchased. This vein appears to have been discovered by John Wolf some time in 1852. In May 1868, when the New York Hill Quartz Mining Co. was formed as a co-partnership, a mill was erected and a small tonnage treated. In 1872 the New York Hill Gold Mining Co. was formed; the shaft was sunk to the 1300-ft. level and a considerable production was obtained; but the mine was closed down in 1883. After purchase by the North Star it yielded $60,000 from 6000 tons, but the vein was small and tight and no new shoots were found.

The total estimated production from the New York

Hill is $1,500,000 from 100,000 tons, the proportion of profitable ground being from 20 to 25% of that opened. At the west end of the New York Hill there is a peculiar vein occurrence, known as the 'slap-up.' Here a vein dipping to the north was discovered and was found to turn over and dip to the south without coming to the surface. This vein is estimated to have produced 35,000 tons yielding, say, $500,000, largely in specimen ore.

In April 1903, the Gold Hill property was purchased. This vein was discovered by George Knight in September 1850, and was the first discovery of gold-bearing quartz in the district, if not in California. It is supposed to have produced several million dollars from a body of quartz lying on the surface, a little distance from the outcrop of the vein. The output of gold from this discovery is said to have caused the gold buyers to put down the price of the metal temporarily, for gold apparently was being found as placer deposits in every valley, and if it were going to form the capping of the hills, as well, it looked as though there might be 'too much of a good thing.' The vein itself, which is the northern extension of the Massachusetts Hill vein, has, except close to the surface, proved generally unproductive, although exploration has been extended to a depth of 1200 ft. on the incline and laterally for a thousand feet or so. The early records show that an English concern, called the Agua Fria Co., of London, attempted to work on Gold Hill, but evidently the water was too cold, as it sold out to Melville Atwood, who was operating the property in 1856. The North Star company, after purchase, did a considerable amount of development, but with no successful results.

In 1910 the Cincinnati Hill property was purchased. This vein had been worked in the early days to a depth of about 150 ft. The outcrop showed a small vein of rich quartz. Mining had been abandoned because the quartz vein was too small to work profitably, although old-timers all said the bottom showed a vein of $20 ore (a standard old-timers' statement, by the way, in this district[2]), and that the shut-down was due to a heavy flow of water (also standard). The shaft was continued by the North Star Mines Co. to a depth of 400 ft., and drifts were driven on a large barren vein; although in one place a small pocket, carrying from two to three inches of specimen quartz, was found, from which a few hundred tons of ore was extracted; but prospecting was discontinued in 1912, owing to lack of any encouragement to proceed farther.

From the foregoing history of the ups and downs of the veins now owned by the North Star Mines Co. the following facts seem to be salient: Of the five outcrops that have seemed to justify exploration, two, the Cincinnati Hill and Gold Hill, have proved thus far unproductive a short distance underground, although good on the surface. Two, the Massachusetts Hill and the New York Hill, have thus far disclosed ore-shoots that are comparatively small and irregular, though profitable when found; while the fifth, the North Star, with a cropping of quartz no larger, as far as can be ascertained at this late date, than the New York Hill and the Massachusetts Hill, and far less rich on the surface than the latter, has disclosed ore-shoots the average length of which on the strike is between 400 and 600 ft., and the depth of which along the dip is more than 2000 ft. Furthermore, two, at least, and perhaps three, of the four shoots in the North Star do not outcrop, although the fracture itself has been traced to the surface.

Of the several veins above mentioned, reasonable and encouraging as their further exploration seemed, it must be admitted that, all outlays taken into account, none, except the North Star, has proved itself profitable to the present owners. The North Star, on the other hand, through the opening of the deep levels by the vertical shaft, started on what was practically a new career, with a productive capacity and outlook for persistence equal to any expectation that might have been based on the results obtained in the upper workings; so that the important fact stands out that this vein, which at best is not over 5 ft. wide and at worst pinches to a mere seam, has been profitably developed for a mile on the dip and half a mile on the strike.

[2][And in others.—EDITOR.]

Rand Figures for Six Months

RESULTS of operations on the Rand for the first half of the current year are as follows, according to *The South African Mining Journal*:

	1914.	1913.
Stamps	9,694	9,999
Tube-mills	291	286
Operating, days	151.7	162.6
Duty per stamp, tons	8.78	8.77
Ore milled, tons	12,637,971	13,883,192
Gold output, ounces	4,086,847	4,640,421
Value	£17,359,824	£19,711,256
Value per ton milled	27s. 2d.	28s. 0d.
Total costs	£11,048,887	£12,416,091
Working costs per ton	17s. 6d.	17s. 11d.
Working profit	£5,866,033	£6,762,266
Working profit per ton	9s. 4d.	9s. 9d.
Dividends	£4,215,729	£4,164,143

MINERAL OUTPUT of Ireland in 1913 included the following: The coal production was 82,521 tons, valued at $246,509; iron ore, 60,014 tons, worth $54,943; bauxite, 6055 tons; rock salt, 43,391 tons; and smaller quantities of fireclay, barytes, copper, soapstone, iron pyrite, and ochre and umber. Quarries employed 3540 people, producing 1,295,961 tons, valued at $695,822. Limestone mined was 582,851 tons; basalt, 460,127 tons; granite, 124,862 tons; and clay, shale, flint, slate, gravel, and sand.

IRON-ORE PRODUCTION of Hungary in 1913 was 2,204,000 tons. Government mines supplied 275,500 tons of this total. The state railways bought a mine in northern Servia. The iron deposits of Hungary are estimated to contain 145,000,000 tons of ore.

The Lampa Copper Smelter, Santa Lucia, Puno, Peru

By FRANCIS CHURCH LINCOLN

The Lampa Mining Co., Ltd., is working a number of small mines in the department of Puno, Peru, and is treating the ore in a copper smelter near Santa Lucia. The home office of the Company is in Liverpool, and J. Lionel Barber is president. Claude Barber is local manager, with office at the smelter. The Lampa Mining Co. was organized in 1906 with a capitalization of £50,000 to work the Santa Catalina mine, six miles northwesterly from Santa Lucia. In June, 1913, the capitalization was increased to £100,000, of which about £65,000 is paid up, to enable the Company to take over the mines and smelter belonging to the estate of William Grundy.

Santa Lucia is a station on the Peruvian Southern railroad 133 miles from Arequipa and 68 from Puno, and has an altitude of 14,250 ft. above sea-level. The main Lampa ('Shovel') camp is at the Limon Verde ('Green Lemon') mine, about a mile from the station and just across the Maravillas ('Marvels') river. A spur is soon to be constructed to connect the camp with the railroad. A general view is shown in the illustration, Fig. 1. The smelter may be seen to the left of this picture, while a nearer view is given in Fig. 2.

The copper smelting furnace is an Allis-Chalmers 36-in. circular blast-furnace. As originally set up at Yarahamba, which is 18 miles from the railroad by a bad road, its cost completely equipped, with Pelton water-wheel to run the blower, is said to have been 10,000 Peruvian *soles*, equivalent to $5000. The equipment at Santa Lucia includes a Baker rotary blower of 16-cu. ft. displacement which furnishes 14 oz. blast pressure and is run by steam, which is generated in a 60-hp. boiler burning *taquia* (llama dung). *Taquia* is found to be much cheaper than coal for fuel. Four tons costing $2.50 per ton is consumed in 24 hours. The smelter is also provided with a square lead blast-furnace built by Robey & Co., which is occasionally operated.

The copper blast-furnace was blown in by the Lampa Mining Co. on January 5, 1914. It has an average capacity of 35 tons per day and uses from 7½ to 10% of coke. The coke costs $31.75 at Santa Lucia and contains 34% ash. The charges weigh 1000 lb., including fuel. The following is a typical example.

FIG. 1. LAMPA, NEAR SANTA LUCIA.

FIG. 2. LAMPA SMELTER.

	Pounds.
Coke	79
Limestone	79
Pyrite ore	210
Foul slag	88
Mixed ores	544
	1000

Copper included, 33 pounds.

Single rail lines connect the dumps of charge constituents with the charging floor, and wheelbarrows are employed having wheels with concave rims which fit over these mono-rail tracks. By this means, the exertion of wheeling is greatly reduced. To overcome the effect of altitude on the air supply, it was found necessary to increase the diameters of the tuyere openings to 1 in. greater than that employed at sea-level.

Matte containing from 40 to 55% copper is made. As much as 2½ tons of 42% matte has been made in one day. The slag runs 39% silica, 41% ferrous oxide, and 8% lime. It contains 0.2% copper. It is calculated that from 12 to 15% flue dust is made. A dust chamber is to be built to reduce this loss.

The foregoing notes give a general idea of what can be accomplished by a small copper smelter operating on the high Peruvian plateau. It may be added that the department of Puno is highly mineralized throughout, and that while the veins are commonly small ones they are numerous and occasionally rich. The principal ores are argentiferous pyrite, silver-copper-lead sulphides, and argentiferous galena, and they readily lend themselves to treatment in small lead and copper blast-furnaces.

Operation of the Oliver Filter in the Globe Mill

By H. A. MORRISON and H. G. THOMSON

The last few years have shown a tendency to the displacement of the submerged leaf by the continuous type of slime filter in the cyanide mills of the United States and Mexico. Of the several forms of continuous filter being used, the Oliver is best known and most popular. It is easy to operate, yet success hinges upon various little known minor details, as shown by the following notes on its operation in the Globe mill at Dedrick, California, and elsewhere.

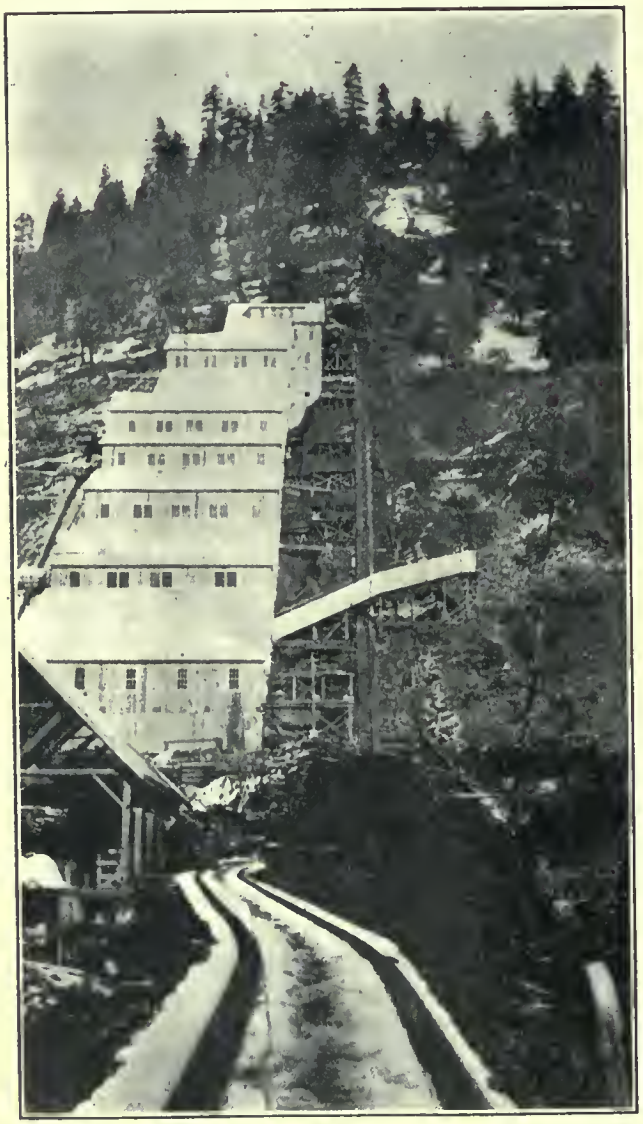

FIG. 1. THE GLOBE MILL AND CYANIDE PLANT.

VACUUM

Methods of obtaining vacuum are widely divergent. Good work cannot be done with a vacuum less than 20 in., and 25 in. is better. Wherever sufficient water under high pressure is available, the simple water ejector, used in the Grass Valley mills and elsewhere, is most commendable. Installation and operating costs are slight and a uniformly high vacuum is easily maintained. At the North Star mills, where E. L. Oliver invented and perfected his filter, novel use of an old mine shaft is made to lengthen the draft tube, 60 ft. fall being secured. At the North Star the ejector has both high and low pressure water connections; available water supply determining which shall be used. The Globe Consolidated is using the form of ejector shown in the accompanying figure (Fig. 2). There, water pressure is 200 lb. per square inch and draft tube is 26 ft. long. Average vacuum maintained on the filter is 25 in. of mercury. This approaches perfection as the altitude is 3000 ft. With the ejector, filtered solution is withdrawn

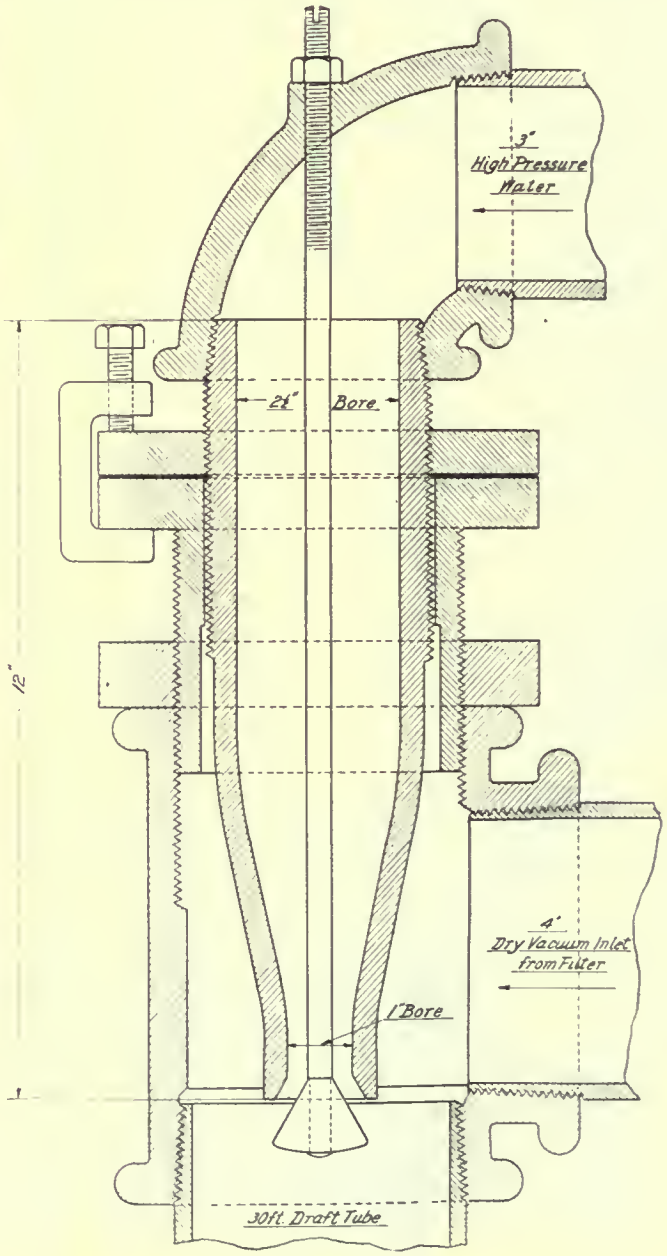

FIG. 2. EJECTOR NOZZLE.

from the vacuum-tank by a small centrifugal pump, but when mechanical means are employed to secure vacuum, the centrifugal is, of course, not needed.[1] However, the latter uses but little power, and, since it handles clear solution, repair costs are negligible.

Most plants have to depend upon some form of vacuum-pump because the large amount of high pressure water needed for an ejector is usually not available. C. H. Urquhart[2] described a special pump used very successfully at the Black Oak, Tuolumne county, California. This pump is a modification of one designed by G. D. Kislingsbury at Minas del Tajo, Sinaloa, Mexico. The Oliver plant at the Black Oak, the pioneer all-sliming plant in California, is a notable one in many particulars.

Feed

Pulp is usually fed so as to enter the filter tank at the top centre on the ascending side of the drum. If coarse material results—the accumulated material acts as a brake upon the revolving drum and finally throws off the driving belt. When this occurs it is wiser to sluice out the tank than to try to force the drum to revolve.

It is desirable to keep alkalinity of feed as low as other considerations will permit as lime salts are detrimental to the cloth and their precipitation in the canvas will necessitate frequent acid washing.

Agitation of Charge

Methods used to prevent settling of charge in the filter tank are sufficient on the average ore, but in certain cases they are inadequate. Internal air-lifts are being used at the Globe with considerable success. There are two air-lifts on the rear and three on the front side of the 16-ft. filter at this plant. Possibly the addition of two or three more air-lifts would entirely obviate the need of mechanical agitation. The agitator now used consists of a longitudinal shaft, fitted with short paddles, running in stuffing boxes placed midway between the lower side of the drum and the bottom of the filter tank. This shaft is driven at about 20 r.p.m. by sprocket and bevel gears. This apparatus is much more effective when a three-inch angle iron the length of the filter is bolted across the ends of the paddles parallel to the shaft. With the latter arrangement, the shaft need be revolved at much less than the above stated speed. The stuffing boxes of the agitator shaft often give trouble. This may be minimized either by feeding a small stream of solution to each gland, or grease may be automatically forced into them by compression cups. If the agitator shaft is sprung or badly worn or if neither solution nor grease is being regularly fed to the glands, it is well-nigh impossible to prevent serious leaks through the boxes. At the extreme bottom of the tank an air agitator is placed

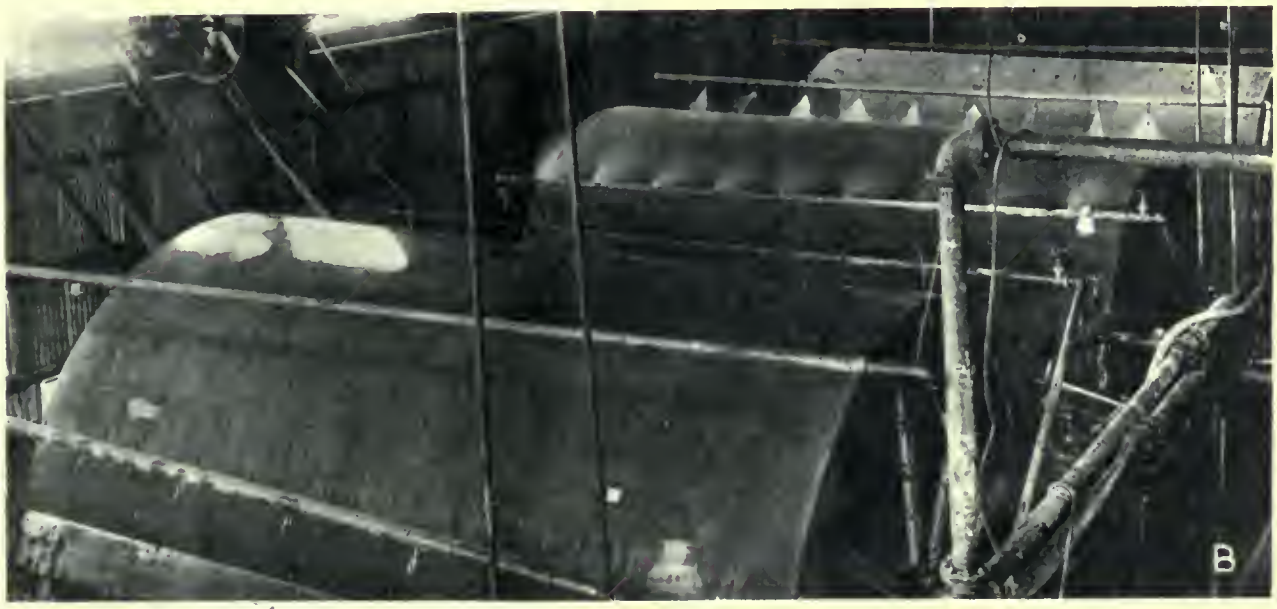

Fig. 3. Oliver filters at the Commonwealth mine, Arizona, showing sprays.

introduced at one end, an abnormally thick cake results on the adjacent portion of the drum and it is correspondingly thin elsewhere. This is particularly true with fast settling ores and in the case of drums more than 12 ft. long. Generally, for all-sliming mills, pulp feed of not less than 1.45 specific gravity (D-2.7) is recommended. Referring again to Grass Valley practice, the Empire pulp is fed at 1.30 specific gravity with good success. However, separate sand treatment is practised and the filter feed is an impervious slime containing no granular material. It will not settle to a density greater than 1.35. With thin feed—1.30 or less—in the average mill, rapid settling together with segregation of

[1][This is true only with 'wet vacuum system.' With 'dry vacuum system' the centrifugal, we understand, is used.—Editor.]

[2]'Black Oak Mill,' by C. H. Urquhart, *Mining and Scientific Press*, November 30, 1912.

lengthwise of the drum. It consists of a length of perforated canvas-covered one-inch pipe with pressure air connections. It is intended for emergency use, when for any reason the mechanical agitator is out of commission, and no doubt has some value if started before the charge has become packed. The canvas covering of this pipe should be renewed once in six months.

When material is settling, the cake shows irregular 'bunches' of coarse sand. If prompt action is then taken, sluicing and the attendant shut-down may sometimes be avoided. This difficulty may arise from one of several causes: (1) inefficient agitation; (2) carrying pulp level too high; (3) specific gravity too low; or (4) poor work in fine grinding machines or classifier. These may be considered in detail.

1. Prevention of settling is absolutely imperative, and this difficulty would seem to have been mastered particularly at Butte, where the Anaconda company has several Oliver filters dewatering concentrates. Incidentally, this marks a further invasion of cyanide machinery into the field of general metallurgy, the attack having been begun by Dorr and others.

2. The best practice is to carry the pulp level about two feet above the bottom of the drum. With exceptional ores—those colloidal in nature—the charge may be safely carried at much greater depths than above stated. When deep charges are permissible, capacity is increased both by the greater vacuum then secured and because a larger cloth area is constantly submerged.

3. As previously stated under the heading 'Feed,' pulp at from 1.45 to 1.60 specific gravity gives best results. Thinner pulp will usually cause trouble.

4. Screen analyses show that the settled material consists largely of fairly coarse sand. At a certain mill the appearance of coarse segregations in the cake is held to prove that grinding or classification is inefficient. This should not be applied too literally, however, with the idea that careful grinding will make it allowable to ignore other possible causes of settling. The small proportion of moderately granular ore in the ordinary mill circuit sometimes concentrates in the filter tank when the precautions above noted are disregarded.

Washing the Cake

Effective displacement of pregnant solution by wash water is of first importance in slime filtration operations. With the continuous type of filter, the period during which wash may be added is necessarily brief; consequently, thorough displacement can be obtained only by careful arrangement of pipes and sprays, close attention to amount of water, and even distribution of the same. Ordinarily capable operators obtain a tailing with soluble content (both cyanide and dissolved metal) equally low as obtained with submerged leaf or pressure filters. The use of perforated pipes discharging water through small holes upon the cake, has been superseded by one of two forms of spray nozzles. The whirling spray (represented by the Vermorel and others) is rather more effective than the fan-shaped form sometimes employed (such as the Bordeaux). The tendency is toward the use of a comparatively large number of individual sprays, each with a relatively small aperture. In mills where volume of solution is a constant, it is customary to have the rear line of sprays arranged so that either barren solution or water may be used at will. The second spray line is placed lengthwise over the crest of the drum and water only is added through it. Sprays intended to handle solution must, of course, be constructed of some metal not attacked by cyanide. Valves for the rear line must be of the most dependable pattern and locked at all times.

The importance of washing is evidenced by the great amount of experimental work along this line which has been done at various mills. A Nevada plant still uses shaking spray pipes. This plan is said to be especially adapted to ores that form an unusually porous cake; also to cases where a relatively large volume of wash solution is essential. It would seem, however, that the

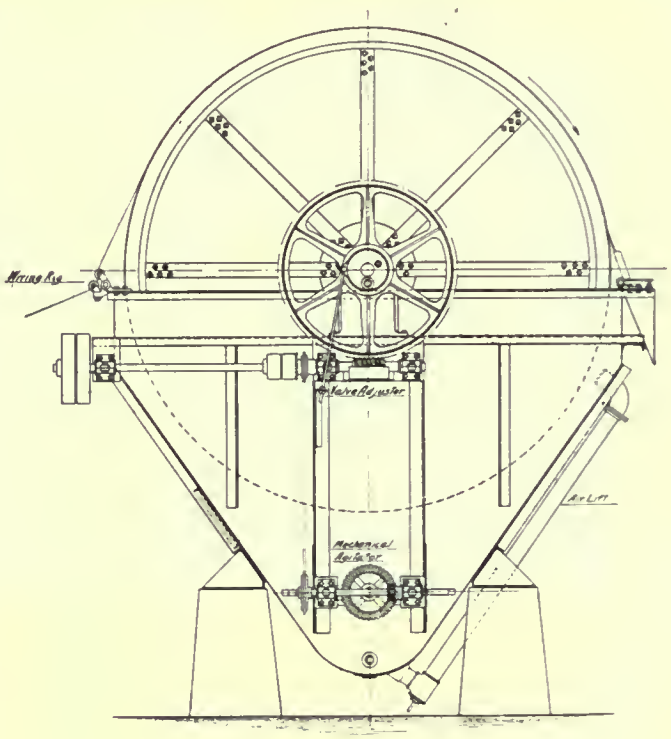

Fig. 4. Cross-section of filter.

atomizing sprays, above noted, would meet either requirement more successfully and would have the additional advantage of effecting a small increase in total extraction. This increase is probably due to the splendid aëration given the cake while being washed with atomizers. Extraction during washing as obtained with the Oliver is certainly less than that secured by filters such as the Butters. In some plants equipped with the latter, this increase is said to approximate 2% of the total recovery. This comparison is hardly fair to the Oliver because the washing period is many times greater in the Butters.

Proper wash water control is facilitated by using a pressure gauge on the spray pipes. When using atom

izers, the minimum permissible working pressure is 25 lb. per square inch; water is not well atomized at less pressure. Average working pressure may be stated at from 35 to 40 lb. Best practice in filter cake washing may be summarized as the even distribution of the greatest permissible amount of wash over the entire exposed cake.

Washing the Cloth

Continuous filter cloths require more frequent acid washing than do those of leaf filters. Scrubbing with 8 or 10-in. ox fibre brushes in a weak hydrochloric acid solution (about 5% HCl) not only restores permeability to the canvas, but also prolongs its life through removal of deleterious lime salts. The benefits of frequent and thorough acid scrubbing are significantly shown at the Black Oak. That mill holds the record for long life of cloth—seventeen months. This cloth was scrubbed weekly with 5% HCl solution.

Lime incrustations render the canvas hard and brittle to such an extent that irregularities of the scrapers may break the cloth or even damage it beyond repair, by catching at those points where rough surface exists. In a certain case, a new filter was operated during two entire months without scrubbing; acid could not be obtained because of inclement weather. The cloth became so impervious that capacity was alarmingly reduced and patching was a daily occurrence. This condition was entirely due to lack of acid treatment; all difficulty immediately vanished when acid was finally applied.

With suitable equipment, three men scrub an 11 ft. 6 in. diam. by 16-ft. filter in one hour. The details of a convenient false valve head to be used while performing the acid washing are shown in Fig. 5. This head confines the vacuum entirely to the three or four sections being treated and pulp level in the tank remains at its normal depth. This ingenious device was originated by Will S. Adams, who is now with the Anaconda company at Butte. For canvas of the size above mentioned, about 20 lb. of commercial HCl is used for each wash, and in some plants this operation need not be performed more often than once a month. As an alternative to scrubbing as above detailed, it is understood that in one case dilute acid is thrown upon the face of the revolving drum. The average cloth life there is stated at five or six months. The inference is that this might be brought up to the general average, namely ten or twelve months, were careful and frequent scrubbing practised.

Sampling and Disposal of Tailing

The scrapers which remove tailing from the face of the drum should have no more than just enough tension to keep them resting lightly against the wires. Under excessive pressure, wear both of scrapers and wires is greatly increased and may even ruin the canvas by tearing it. The scrapers should be filed to a smooth and properly beveled edge once each week. A convenient plan is to have a spare scraper on hand and interchange about once in two months; the one taken off can then be

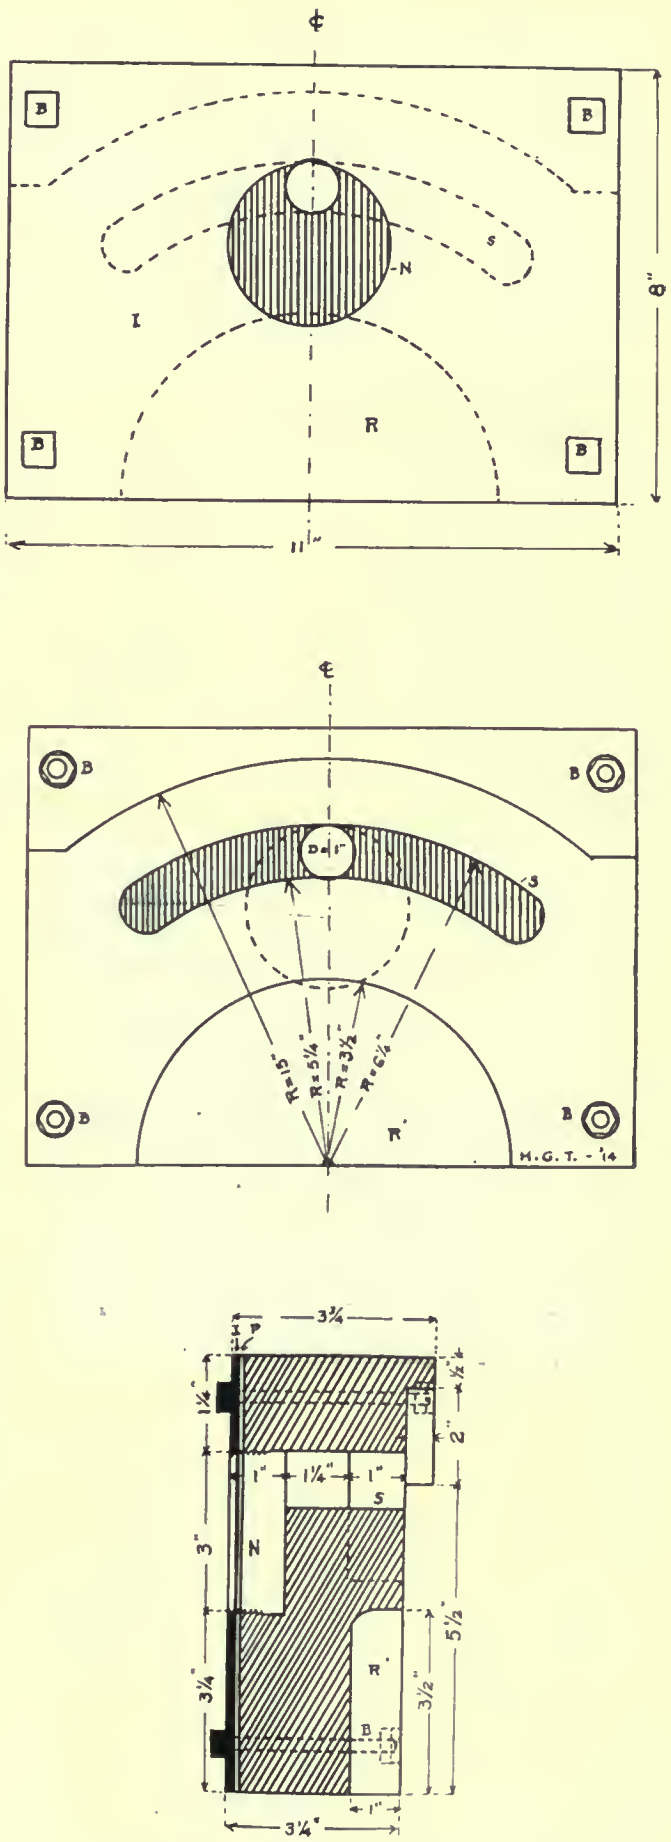

Fig. 5. False Head Used in the Globe Mill; Front View, Rear View, and Cross-Section.

dressed at the convenience of the operator, and very little running time is lost. Two men need 15 to 20 minutes to dress the scraper when it is done each week.

Tailing may be taken away from the filter either by belt-conveyor or sluicing. When ample water is available the latter method is, of course, to be preferred. The 'blow' should be only strong enough to slightly loosen the cake, usually under 10 lb. If too much pressure air is admitted, pregnant solution is blown through the cloth and the soluble losses thereby increased. The practice of taking tailing samples at a point above the section being blown off is to be condemned for the above reason, and samples are uniformly slightly lower in value than the actual loss in the material being discharged. Samples should be taken at intervals of not more than one hour, along the edge of the scraper from end to end of the drum. Whenever feasible, particularly where sluicing is practised, occasional check samples should be taken. Such samples are not infrequently higher than the regular ones. This is caused by the very human tendency to secure low assays when such results are desirable, by segregations of concentrate and coarse material, and by momentary variations in vacuum, wash water and 'blow.' Harai R. Layng has recently published some valuable data[3] covering this

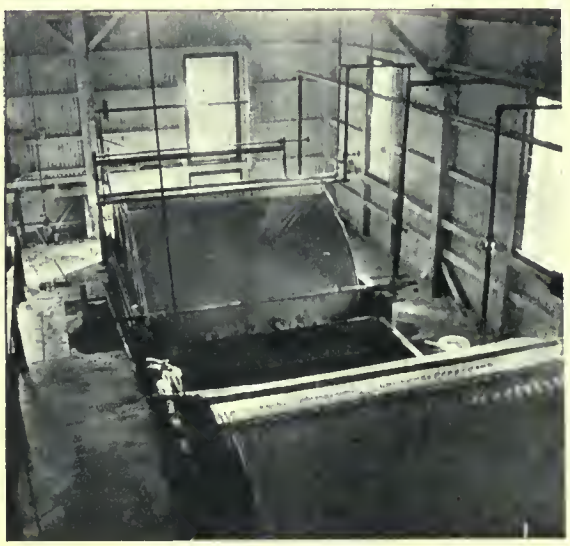

FIG. 6. OLIVER FILTERS IN THE EMPIRE MILL AT GRASS VALLEY.

point in the case of the Butters filter at a well managed Nevada mill. His findings are also applicable to the Oliver.

As in other types of filter, Oliver tailing losses consist, in part, of dissolved metal which the wash has failed to displace. The appended tables are incomplete because comparable figures are hard to get, but they will at least suggest the tenor of such losses.

CONCLUSIONS

It is believed that this filter may be safely recommended as well fitted for general use in dewatering slime of whatever nature with the possible exception of colloids. The latter can be handled only at a greatly reduced capacity; this also applies to filters of other form. We believe the Oliver to be the best machine for general use with average quartz ores.

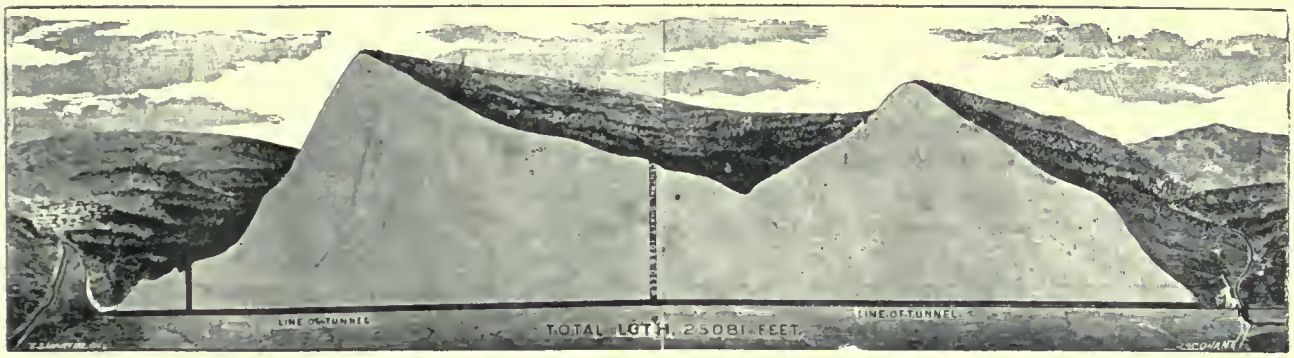
[5]Variations in soluble loss at the Black Oak are partly due to wide fluctuations in value of ore treated. Other causes of non-uniform soluble loss were; filter being operated above rated capacity, shortage of wash water, and low pressure of water. Displacement is usually even more complete than this table indicates.



HOOSAC MOUNTAIN RANGE FROM THE NORTH, SHOWING THE LINE OF THE TUNNEL

Driving the Hoosac Tunnel and the Lessons it Taught

By P. B. McDONALD

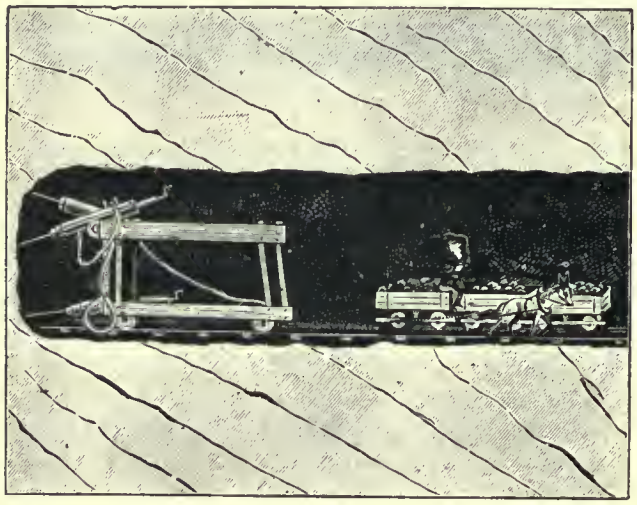
In view of recent improvements in rock-drill practice, and the increased attention paid to underground work generally, it is interesting to compare modern rock excavation with the methods in use fifty years ago. From 1854 to 1875 there was under construction in Massachusetts what is still the longest railroad tunnel in the United States, the famous Hoosac tunnel. This tunnel, 4¾ miles in length, which required 21 years and $10,000,000 to complete, has additional interest because in driving it there were used, for the first time in tunneling in America, power rock-drills, air-compressors, nitroglycerine for blasting, and electricity for firing blasts. The modern rock-drill and mine explosives owe a great deal to the Hoosac tunnel, where many of the initial problems connected with their practical use were solved. It is odd that the state of Massachusetts, which has never been a mining state, should bring into use in America such important innovations as power-drills and nitroglycerine. For several years previous to 1875, a force of 800 Cornish, Irish, and French-Canadian miners worked at the tunnel, with its accompanying problems of shaft sinking, and during that period the northwestern corner of Massachusetts resembled a Rocky Mountain mining camp. Altogether, 195 men lost their lives in the 21 years required to make 'the great bore,' as it was called, and this list of fatalities was not considered especially remarkable, as the Mont Cenis tunnel in Europe, completed shortly before, had cost 1000 lives.

Hoosac mountain is part of the Green Mountain range extending through western Massachusetts, and had, up to the opening of the tunnel, formed a natural barrier between the states of Massachusetts and New York. Boston capitalists desired a direct route between Boston and the West, and it was seen that, except for Hoosac mountain, the river valleys made the route a comparatively easy one. One of the important questions which arose when the tunnel was suggested, concerned the geological character of the mountain. Edward Hitchcock, of Amherst College, was consulted and gave his opinion before the Massachusetts legislative committee that the rock to be cut would be micaceous slate with occasional seams of quartz; the ground, he thought, would not be especially hard to drill and but a small part would require arching. This prophecy in most respects proved strikingly correct, the only important variation being at the western end of the tunnel, where much soft rock was found that required careful and expensive arching. However, the rock in general was harder than had been expected, and resembled schist rather than slate.

In 1851, work was begun on the eastern end of the tunnel with a ponderous boring machine weighing 75 tons; cutters or knives were made to revolve in a circle 24 ft. in diameter, and after each short run had been made the machine was backed away, and the centre or core blasted out. After boring 10 ft., the machine struck a quartz seam and refused to bore farther. Discouraged, the company in charge deferred operations, until in 1854 a contract was let to Herman Haupt & Co. Incidentally, Herman Haupt was later a famous general in the Civil War. His company worked on the tunnel until 1862, using hand-drilling and black powder; the progress was at the same time slow and the cost high. So dark did matters look, and so much opposition was encountered in political quarters that in 1862 a pamphlet was published in Boston entitled 'The Road to Ruin, or the Decline and Fall of the Hoosac Tunnel.' At this point, the state of Massachusetts took the matter into its own hands, and investigations were directed into power-drills and air-compressors which were being used in the Mont Cenis tunnel between Italy and France. Finally, in 1868, some contractors were found who gave promise of finishing the work. They were the Shanley brothers of Montreal, and they agreed to complete the tunnel by March 1, 1874, for $4,594,268. At this time, about one-third of the work had been done and many millions had been spent. The Shanley brothers succeeded admirably, and on November 27, 1873 (Thanksgiving Day) the final blast was made that connected the two headings. The first train went through on February 9, 1875.

The first air-compressors used on the Hoosac tunnel

were built by James Hunter & Son of North Adams, Massachusetts. These together with a number of others manufactured by the Burleigh Rock Drill Co., of Fitchburg, Massachusetts, were in operation until the completion of the tunnel. In place of building two or three large compressors such as would be used today, dozens of small ones were constructed; thus at the west shaft plant alone there were 25 compressors. There is, at the



TUNNEL HEADING SHOWING DRILL CARRIAGE.

abandoned Beaufort iron mine near Michigamme, Michigan, an old compressor said to have been used on the Hoosac tunnel, and it looks the part. It has a small vertical engine, and huge flapper valves on the two air-cylinders; the entire construction is especially heavy, but the compressed-air outlet for pipe attachment looks disproportionally small. Air at from 55 to 60 lb. pressure was used in the tunnel.

The first drilling machines were complicated, costly, and failed to do the work; it was difficult to get a drill which would hit hard fast blows and not jar to pieces from the impact. Finally the Burleigh Rock Drill Co. perfected a machine which was comparatively light and simple; it struck 300 blows per minute. For use in the tunnel these drills were mounted on drill carriages on wheels, four drills on a carriage. It is interesting to note that modern European practice in rock-drilling (reputed to be superior to American practice) still uses drill carriages; and shorter holes than are common in America are drilled and blasted. The use of drill carriages does away with the slow process of rigging up columns or tripods, and facilitates moving the apparatus back and forth when blasting; they are probably not so flexible for pointing the holes. Records of the rock-drill work in the Hoosac tunnel state that "a hole from 4 to 5 ft. deep could be put down in an hour." The modern reciprocating rock-drill would probably accomplish this in 10 or 15 minutes. It is recorded that the greatest heading advancement in any month of the work was 184 ft., driven from the central shaft in September 1873. As a comparison, the Mount Royal tunnel of the Canadian Northern railway, near Montreal, was driven 810 ft. in one heading through hard limestone during 31 working days in May 1913. Allowance should be made, however, for the fact that although on the Hoosac tunnel there were three 8-hour shifts per day, there was no Sunday work; and that September has one less day than May. In driving the Hoosac tunnel, a heading 8 ft. high by 24 ft. wide was carried ahead, 500 ft. beyond the enlarged part. This heading was in the middle of the enlarged section; that is, to enlarge to the full size, 22x24 ft., a slice was taken off the top, as well as the bottom taken up. Temporary tracks for tram-cars were maintained on the 500-ft. stretch from the end of the heading to the enlarged section, and a light trestle constructed at the bench to facilitate dumping rock from the upper-level cars into the lower-level cars.

There were no high temperatures to contend with in the tunnel, on account of the moderate height of the mountain above: the flow of water was comparatively small and did not give much trouble, although there were one or two bad freshets in spring. Many stories are still told by old residents concerning the odd incidents of these early days of tunneling in America. The city of North Adams, at the western portal of the tunnel, was then a lively place for a New England town, and many a free-for-all fight took place between the 'Cousins Jacks' on one side and the Irish or 'Cork men' on the other, especially after celebrating a 'holing-through' or shaft-sinking exploit.

Early Drill Valves

It has been stated that the history of the Hoosac tunnel is the early history of rock-drill development in America. The drills used in the tunnel were, of course, not nearly as efficient as the modern types. The designers had no precedent to follow as to valves and construction, and the only suggestions available had to be derived from steam-engine practice. Thus the first rock-drills were much too heavy and cumbersome. Lighter, simpler drills were designed later, but with valve motions which, although suitable for steam-engines, did not give satisfactory results for the peculiar functions of a rock-puncher. Most of the early rock-drills had some form of rocker-thrown slide valve. It was not until later that air-thrown valves came into use, and the early types of spool-valve drills had three spools all of the same size.

The modern spool valve and the Butterfly valve represent the best differential air-thrown valves, and it is generally conceded that they are faster and more efficient than the tappet-valve type. Tappet-valve drills had a long run of popularity because, like tappet-valve pumps, they do not easily get out of order, even if they are slower than other types. Air-thrown valve drills are disliked by some miners because of their tendency to freeze; however, later types have remedied this to a large extent.

Until 1865, the principal explosive used was black powder, or 'gun-powder,' as it was called. Now black powder is rarely used in underground rock work, but on account of its slow explosive action is used in open cuts where it is desired not to scatter the débris too

much. In 1867, George Mowbray was requested to come to North Adams, and a contract was made with him to supply glycerine for the tunnel. A factory was completed near the west shaft, and Mr. Mowbray began to manufacture 'tri-nitroglycerine,' his own invention, which proved a success. This was the first time that nitroglycerine was successfully used in important tunneling or mining work in America. The method of blasting was as follows. After the holes were drilled, the liquid glycerine was brought into the tunnel in copper cans from the magazine and poured into tin tubes about $1\frac{1}{2}$ inches in diameter, varying in length according to the depths of the holes drilled. For a hole 10 ft. deep, a tube or cartridge 3 or 4 ft. long would be necessary, containing 3 lb. of glycerine. Into the end of each cartridge an electric fuse or exploder was inserted, to which were attached connecting wires for electrical firing. A number of accidents occurred, as would be expected in the introduction of a powerful new explosive, but it is stated that there were fewer accidents than with the black powder previously used.

It can be imagined that carrying liquid nitroglycerine around the shafts and tunnels in copper cans, and tamping tin tubes of it into drill-holes for blasting was 'no job for a nervous man.' When black powder was used, 5 pounds per cubic yard of rock broken had been necessary; with nitroglycerine the quantity per cubic yard was about 3 pounds.

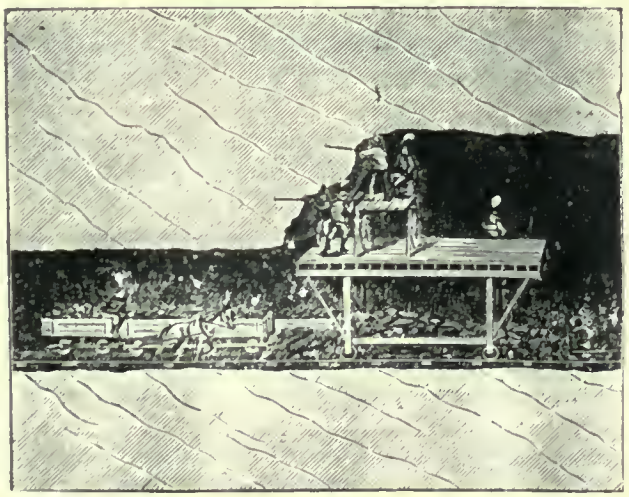
Two shafts were sunk to the tunnel. The west shaft, which is now filled, was sunk for the purpose of affording another heading so that the tunnel could be driven east more rapidly, as at the west end, progress was slow, due to the loose nature of the rock, which required arching with brick 7 to 12 courses thick. The west shaft was 318 ft. deep and was sunk only 3000 ft. from the west portal. The central shaft, 1028 ft. deep, was situated between the two peaks of Hoosac mountain, about 600 ft. west of the centre of the tunnel, on account of a brook at the central point, which it was feared would overflow into the shaft. The central shaft was planned for ventilation purposes, and is still open. It was started in 1863, and was a long time in being sunk on account of the difficulties encountered. A very bad accident occurred in 1865 at the central shaft when gasoline, used in lighting, took fire in the shaft house. Thirteen miners had just been lowered into the shaft, then 583 ft. deep. The fire spread so rapidly that the engineer had no chance to hoist the men. All the buildings at the shaft mouth were soon on fire. Several tons of drill steel was in the shaft-house directly over the shaft, and as the structure burned, a shower of steel and burning timbers fell upon the men below. The following day a miner, Thomas Mallory, was lowered on a rope into the shaft to see if by chance any of the thirteen men were alive; in 40 minutes he pulled the rope to be hoisted and reached the surface just as he fainted. He reported 15 or 20 ft. of water in the shaft, and no trace of the men. The bodies were not recovered until a year afterward, when the shaft was pumped out, and only a few could be identified.

Connecting the Headings

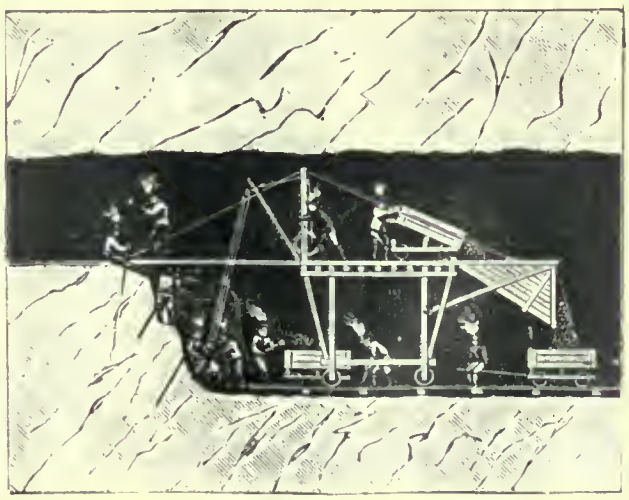
After sinking the central shaft, driving was commenced both to the east and west to meet the tunnel headings, and thus the progress was accelerated. The drift to the west was advanced 2006 ft., that to the east 1563 ft. The surveying for these 'holing-through' problems, where such a long tunnel and such rough surface were concerned, was naturally a difficult job. It was accomplished with remarkable accuracy, the east headings met with an error of $\frac{7}{16}$ of an inch, the west headings with an error of $\frac{5}{16}$ of an inch.

The Mont Cenis tunnel, where there were no shafts, had closed a few years before with an error of about half a yard, which was considered extremely fortunate.

It is evident that the central shaft of the Hoosac tunnel, from which headings were driven in both directions, complicated the surveying a great deal more than would have been the case had there been no shafts. In those days 'plumbing the shaft' problems had not been systematized to the extent that exists now, and the engineer in charge had to figure out methods of his own. The en-



ROOF ENLARGEMENT AT EAST END.



TUNNEL ENLARGEMENT AT WEST END.

gineer was Carl O. Wederkinch, a Dane, who later had charge of the engineering on the Sutro tunnel of the Comstock lode.

In the work of 'plumbing' the central shaft, Mr. Wederkinch used elaborate apparatus at the top of the shaft. Stone piers were built 25 ft. on either side of the shaft, "on each of which was placed and securely fastened an instrument consisting of slides, divided scales, motion-screws, clamps, etc." An average of a great number of lines was taken to establish the true tunnel direction across these piers; two parallel steel wires were stretched close together across the shaft between the piers; the intervening space of about a twentieth of an inch represented the true tunnel line. Exactly between these wires, not touching either, were suspended two plummet wires of copper on each side of the shaft; these wires were 23 ft. apart, that being the maximum distance possible. On the end of each wire, one thousand feet below, was attached a plummet weighing 15 lb.; each wire was encased in a wooden box to protect it from the disturbing effect of dripping water, air currents, etc., and the plummets were immersed in buckets of water. Even with all this protection, the wires at the bottom of the shaft, where sights were taken, had a slight movement, and the engineer took a great number of different observations to determine the true underground line.

Surveying the Tunnel Line

All the surveying methods were similar to those used in modern practice, but, having more precedent to follow and better instruments, the modern engineer would not need to take such elaborate precautions. It happens that Hoosac mountain has two summits over the tunnel, about three miles apart, one near the eastern portal and one near the western (see profile in sketch). Before the tunnel was started, on each summit there was built a signal-house of masonry, the signal-houses being situated on the tunnel line. On top of each signal-house, an iron pole 15 ft. high and of 2-in. diameter, was placed exactly on the true line. Then this true tunnel line was extended eastward several thousand feet beyond the proposed east portal, across Deerfield river to a point on the hill beyond, where another pole was erected. The tunnel line was also extended westward across Hoosac valley to a point on the hill beyond, where a signal-house was erected. Thus a straight line from the flag across Deer river to the flag across Hoosac valley was the true tunnel line, and passed through the poles on the two summits of Hoosac mountain. Each flag across the river valley could be seen from the corresponding portal of the tunnel. It is thus evident that, although the country over the tunnel is rough, the hills were convenient for long sights and rendered the surface surveying simple.

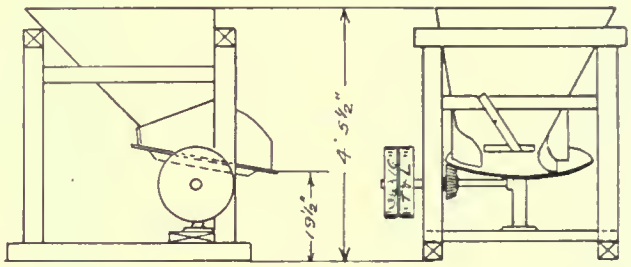
White arsenic produced in the United States in 1913 amounted to 2513 tons, valued at $159,236. There was 4687 tons, worth $570,000, imported, mainly from Europe. The American output is a by-product from smelters.

Improved Ore Feeder

By ULYSSES B. HOUGH

In your issue of May 23 you speak of a new ore feeder similar in design to the well known Challenge feeder, but with fewer parts. In many cases it is found desirable to have a constant flow of ore to rolls and belt-conveyors in lead-silver concentrating plants, where large tonnage is handled, which neither this feeder nor the Challenge will handle, both being limited to 75 to 80 tons in 24 hours and an intermittent discharge.

To meet these requirements, such feeders as the pulley-feeder for constant flow, various plunger feeders, and the Tullock feeders have been brought out. In my work in the Coeur d'Alene, Idaho, mining district, I have succeeded in remodeling the Challenge feeder to meet the requirements as to moving parts, constant flow of ore, and quantity of ore that the machine can be made to feed, beside being noiseless so far as the feeder itself is concerned.



I remove all gearing, aside from the pinion, extend the pinion shaft as shown in the cut, place two pulleys, a tight and a loose, on the extended shaft, and belt to any suitable drive. The feeder plate of this feeder has 56 teeth and the pinion 24; 4⅓ revolutions per minute of the pulley shaft will give two revolutions to the plate. The feeder running at this speed will feed 250 tons of ore crushed to pass a 30 or 36-mm. screen in 24 hours. The same feeder with an increase of speed can be made to feed three or four times as much ore: in fact, any quantity one may wish. A variation as to quantity can be had by regulating the feed-regulator plate in the front part of the machine. A finer and steadier feed could not be desired.

Another improvement is to bolt a false plate on the top of the revolving disk to take the wear. In this way the gear teeth on the lower side of the plate can be preserved for years, by replacing the false plate when worn out. A steel plate ¼ in. thick, cut to shape, serves the purpose well for a false plate. Some dozen or more feeders arranged in this way are used in the Coeur d'Alene mining country and are giving satisfaction.

While such an arrangement of feeder would not appeal to a stamp-mill man who only wants a small tonnage fed to the stamp-mill, it certainly does appeal to a concentrator man who wants a steady flow of ore and large tonnage as in the lead-silver and copper concentrating mills.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Valuation of Dredging Ground

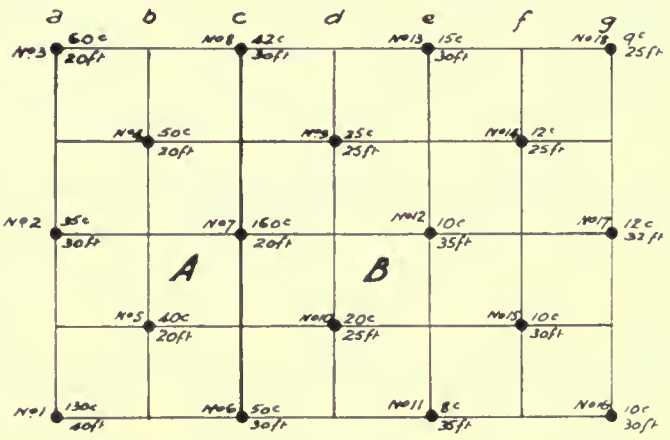
The Editor:

Sir—Mr. Decoto's article in your issue of May 29 is of timely interest, but it would have been of greater value had he based his calculations on a proper interpretation of the drilling results. The ideal he has in view as he expresses it, is one which must commend itself to all engineers as well as to the investing public, and the broad question raised is equally important in any other class of mining. "The relation of the actual recovery" to the average gold content is of the foremost importance in all mining and metallurgical operations on account of its being one of the principal factors measuring the profitableness of the operation, although it is somewhat difficult to discern where the author has touched upon that question. That there has been "a lack of proper understanding of the valuing of a dredging area" is quite apparent to anyone who has followed the results obtained by various dredging companies in different parts of the world and compared these results to the values reported from the drilling operations. It is surprising that one who endeavors to point the way for the guidance of others, possesses such an apparent lack of comprehension of the principles which underlie the estimation of ore in sight, if I may be permitted to use that expression in this case, because the principles underlying the estimation of quantities and gold content of dredging ground are the same as apply in hard rock. It is a little unfortunate that the author should use the expression 'valuing' as applied to finding the average of the results of certain drill holes. The valuing of the ground comes later and must include the various factors that contribute to the cost plus the recovery that may be expected.

In order to make what follows clearer, I reproduce herewith Mr. Decoto's diagram, except that I have put in the correct value of hole No. 7 as 160c., which is the figure taken in his subsequent calculations, and further have lettered the lines of holes *a* to *g*, as shown.

The first thing that strikes one on examining this assay plan is the existence of two erratic high results, No. 1, 130c., and No. 7, 160c. It seems to me that in ordinary practice these erratic high results would be eliminated or reduced to the general average of the block or of the holes in the immediate vicinity. The method to be adopted, would of course depend upon circumstances and the judgment of the engineer; but that they should be reduced, there can be no doubt. However, in order not to complicate the discussion, the original figures will be used in the following calculations.

Mr. Decoto states "obviously to obtain value of gold content per cubic yard for the entire area, it would be necessary to multiply the gold content of each hole by the depth of the hole, add the total of these products, and divide this sum by the total of depths of the holes." *Obviously* this is *not* the way to secure the average value of the ground in question, and as a rule for universal application it is entirely false, although it may serve under one particular set of conditions. The usual method of placing drill holes is as shown in the diagram, namely, at the intersection of coördinates. If instead of this the holes were spaced at the apices of equilateral triangles so that any hole was equi-distant from any adjoining hole, a much simpler method of calculation could be adopted and the rule given by Mr. Decoto used.



MAP OF DRILL HOLES.

It is of course sometimes impossible to space holes at regular intervals, much less at equal distances from each other and any rule to be of universal application must give a correct result regardless of the distance between the holes. In my book, 'Mine Sampling and Valuing,' on page 101, an illustration is given of an error amounting to 10% that may arise from incorrectly averaging the results of irregularly spaced drill holes in a copper deposit. The same principle applies in the present case. By reference to Mr. Decoto's diagram, it will be seen that weighting each sample equally, as he does the varying distance between the holes is entirely disregarded, and therefore the result cannot possibly be correct.

The chief error, however, is not on that account because in this particular case the distance between the

holes does not affect the result to any very marked extent. The principle which underlies the averaging of samples is that "a sample is supposed to represent the ore half way between it and the next sample; with the terminal samples, ore only on one side is taken into the calculation."[1] This definition applies equally to alluvial ground and if we gauge Mr. Decoto's calculations according to this rule, it is apparent that the results of the individual holes are not weighted proportionally to the volume of ground they represent. For example, in area A the terminal samples 1, 3, 8, and 6, are given double the weight to which they are entitled, as also are samples 11, 13, 18, and 16 in area B. Mr. Decoto calculates the average of the whole area and then divides the ground into two "one bounded by the test holes 1, 3, 8, and 6, calling it area A and the other bounded by No. 9, 10, 16, and 18, calling it area B." That the results he obtains are incorrect is demonstrated by combining his averages of areas A and B, allowing for the proportional volume of ground which each represents, and the result secured is different from his original average value for the whole area. I will show how this is arrived at a little later.

It is sought to obtain the average value of the ground *within* the drill holes, as shown in the diagram. The proper method of procedure is first to find the average of the results of each line of drill holes as representing a particular cross-section of the area and then to combine these, proportioning each to its area and assay value. The factor of the distance between the individual intervals can be disregarded because it is the same in each case. In making the calculations, whether for an interval or for a block, proper allowance must be made for the terminal holes, or terminal intervals.

I therefore submit the following calculations:

AREA A

LINE *a*.

Hole No.	c.		ft.		ft. c.
1	130	×	40	=	2600
	2				
2	35	×	30	=	1050
3	60	×	20	=	600
	2				
			2)60		)4250 ft. c.
			30		70.8 c. for average depth of 30 ft.

LINE *b*.

Hole No.	c.		ft.		ft. c.
4	50	×	20	=	1000
5	40	×	20	=	800
			2)40		)1800
			20		45.0 c. for average depth of 20 ft.

LINE *c*.

Hole No.	c.		ft.		ft. c.
6	50	×	30	=	750
	2				
7	160	×	20	=	3200
8	42	×	30	=	630
	2				
			2)50		)4580
			25		91.6 c. for average depth of 25 ft.

[1] 'Mine Sampling and Valuing,' page 93.

AREA B

LINE *d*.

Hole No.	c.		ft.		ft. c.
9	25	×	25	=	625
10	20	×	25	=	500
			50)		1125
					22.5 c. for average depth of 20 ft.

LINE *e*.

Hole No.	c.		ft.		ft. c.
11	8	×	35	=	140
	2				
12	10	×	35	=	350
13	15	×	30	=	225
	2				
			2)67.5		)715
			33.75		10.6 c. for aver. depth of 33.75 ft.

LINE *f*.

Hole No.	c.		ft.		ft. c.
14	12	×	25	=	300
15	10	×	30	=	300
			2)55		)600
			27.5		10.9 c. for aver. depth of 27.5 ft.

LINE *g*.

Hole No.	c.		ft.		ft. c.
16	10	×	30	=	150
	2				
17	12	×	32	=	384
18	9	×	25	=	112
	2				
			2)59.5		)646
			29.75		10.9 c. for aver. depth of 29.75 ft.

To get the average of the whole block weighting the terminals, or in this case lines *a* and *g*, at one-half, calculate as below:

Line.	Cents.		Feet.		
a	70.8	×	30	=	1062
	2				
b	45	×	20	=	900
c	91.6	×	25	=	2290
d	22.5	×	25	=	562
e	10.6	×	33.75	=	358
f	10.9	×	27.5	=	300
g	10.9	×	29.75	=	162
	2				
			161.15)		5634
					34.96 c. for aver. depth of 26.9 ft.
					say 35 cents

which is the correct calculation based on the figures given, but is still too high on account of the inclusion of the two erratic high results noted at holes No. 1 and No. 7.

In calculating the average of the areas A and B, Mr. Decoto omits a portion of the results which obviously must be included in finding the average value of the block of ground. In the calculations for area A, the terminal lines *a* and *c* should only be weighted one-half, and in securing the average in area B, line *c* should be taken into the calculations and weighted one-half, just the same as line *g*. Mr. Decoto omits entirely from his calculations the results obtained along line *c*, so that the block of ground between lines *c* and *d* is not included in the result he obtains.

The proper results are found as follows:

Again weighting terminals at half

AREA A

Line.	Cents.		Feet.		ft.	c.
a	70.8	×	30	=	1062	
		2				
b	45	×	20	=	900	
c	91.6	×	25	=	1145	
		2				
					47.5)3107	
					65.4	c. aver. value for a depth of 23.7 ft.

AREA B

Line.	Cents.		Feet.		ft.	c.
c	91.6	×	25	=	1145	
		2				
d	22.5	×	25	=	562	
e	10.6	×	33.7	=	359	
f	10.9	×	27.5	=	300	
g	10.9	×	29.7	=	162	
		2				
					113.65)2526	
					22.2	c. aver. value for a depth of 28.4 ft.

The difference between these results and those given by Mr. Decoto are quite startling, and in the case of area B amounts to approximately 75 per cent.

I do not wish to lengthen this discussion unnecessarily, but I will show that if the results of holes No. 1 and 7 are reduced to their proper figure, the difference is still more startling. In order to prove that Mr. Decoto's method of calculation is incorrect, I will check his results.

Take his figures for the average value of area A at 72.42c., and the average value of area B at 12.72c. It is obvious that the average of the two blocks is proportional to the cubic contents of each block and its average value. Therefore, if we assume the area of

Area A = 2,
then Area B = 4.

The area multiplied by the average depth gives the cubic content, and multiplied by the assay value gives the gold content of each.

In order to find the average of these two blocks, make the following calculations, taking average depths from his figures:

Area.	Depth.		Area.		Volume.		Cents.		vol. c.
A	26.2	×	2	=	52.4	×	72.42	=	3795
B	29.2	×	4	=	116.8	×	12.72	=	1484
			6		)169.3		169.3)5279		
							31.2	c. aver. value for a depth of 28.2 ft.	

The resultant average as shown, 31.2c. per cubic yard, compares with 37.69c., Mr. Decoto's original figure. *Both are wrong.* To check the averages I have found, calculate as below:

Area.	Depth.		Area.		Volume.		Cents.		vol. c.
A	23.7	×	2	=	47.4	×	65.4	=	3100
B	28.4	×	4	=	113.6	×	22.2	=	2522
					161.0		161)5622		
							34.92	c. aver. value for a depth of 26.9 ft.	

This figure checks the previous calculation.

Let us go one step further and calculate the average value of the ground with reduced assays for holes No. 1 and No. 7. Taking the diagram as a guide, it seems to me that it will be fair to give No. 1 a value equal to the average of the three holes adjacent to it, namely, No. 2, 5, and 6. Thus 35 + 40 + 50 = 125, divided by 3, gives 42c. as the reduced assay for hole No. 1. Likewise, give No. 7 a value equal to the average of the four holes surrounding it, namely, No. 4, 5, 10, and 9. Thus 50 + 40 + 20 + 25 = 135, divided by 4 = 34c. as the reduced value of hole No. 7.

The following calculation may then be made to secure the average value of area A:

AREA A

Line *a*.	Cents.		Feet.		ft.	c.
1	42	×	40	=	840	
		2				
2	35	×	30	=	1050	
3	60	×	20	=	600	
		2				
					60)2490	
					41.5	c. aver. value for a depth of 30 ft.

Line *b* from preceding calculation gives 45c. for an average depth of 20 feet.

Line *c*.	Cents.		Feet.		ft.	c.
6	50	×	30	=	750	
		2				
7	34	×	20	=	680	
8	42	×	30	=	630	
		2				
					50)2060	
					41.2	c. aver. value for a depth of 25 ft.

Combining these,

AREA A

Line.	Cents.		Feet.		ft.	c.
a	41.5	×	30	=	622.5	
		2				
b	45	×	20	=	900	
c	41.2	×	25	=	515	
					47.5)2037.5	
					42.9	c. aver. value for a depth of 23.7 ft.

To get the average of area B:

AREA B

Line.	Cents.		Feet.		ft.	c.
c	41.2	×	25	=	515	
		2				
d	22.5	×	25	=	562	
e	10.6	×	33.7	=	357	
f	10.9	×	27.5	=	300	
g	10.9	×	29.7	=	162	
		2				
					113.65)1896	
					16.7	c. aver. value for a depth of 28.4 ft.

Combining these results gives the average for the whole block.

Area A	23.7	×	2	=	47.4	×	42.9	= 2033.5
Area B	28.4	×	4	=	113.6	×	16.7	= 1897.1
					161.0		161)3930.6	
							24.4	c. aver. value for a depth of 26.9 ft.

This result of 24.4c. compares with that of 35c. where the erratic results of holes No. 1 and 7 are included and Mr. Decoto's original figure of 37.69c. which is 54.4% too high.

It is a pity Mr. Decoto did not use his data more advantageously. His failure to arrive at a proper conclusion is not uncommon among men who should know better. It indicates a failure to grasp the basic principles underlying mine sampling and valuing. There are still too many rule-of-thumb methods in vogue, and many of the failures of mining companies to realize estimates are due largely to "a lack of the proper understanding" (as Mr. Decoto puts it) of the essential principles of the business.

In conclusion, I would like to suggest the advisability where possible of placing holes equidistant from one another in every direction, so that any three will form an equilateral triangle. In such a case the volumetric average of any group of holes will give the average of the ground, assuming the values to extend half the unit distance outside the holes.

C. S. Herzig.

London, June 18.

True Fissure Veins

The Editor:

Sir—Referring to 'true fissure' veins in your issue of September 19, I believe the matter is timely and that the discussion of this time worn and much commercialized term is worthy of some space in your columns.

That the 'true fissure' vein as described in the textbooks is principally idealistic in its nature, is a conclusion soon reached by those having the opportunity of studying the veins of many mining districts. But, to the prospector, the promoter, and the layman this nomenclature has a particular significance. The prospector's vein must be a 'true fissure' because he has been led to believe that all such veins have extensive orebodies which go down to great depths. The promoter uses the appellation to influence the layman (who conceives in his mind a deep fissure or cavity in the earth's crust which was subsequently filled with ore) to invest in his venture. However, for mining engineers the term 'true fissure' should have but little application.

In the majority of cases it is found, upon close examination, that the so-called 'true fissure' veins are probably due to metasomatic filling rather than to direct precipitation on the walls of open fissures, strong evidence of the ore and vein material having been the result of the mutual exchange of minerals between the country rock and the circulating solutions, being detected. Veins of this kind always have at least one wall which is formed by the fissure or fracture through which the mineral-bearing solutions circulated while exchanging minerals with the adjacent formations.

Often such replacement mineralization takes place only on one side of the fissure or fracture, due probably to some impervious material, as gouge or clay formed by faulting movement; but sometimes it is found to have occurred first on one side and then on the other along the strike, so that the fracture forms the hanging wall of the vein in one place and the foot-wall in another. In other instances the replacement extends across between two parallel fractures, faults, or fissures, whichever they may be or you may wish to call them. In this manner both walls of the vein are developed, and this is probably the nearest approach to the traditional 'true fissure' vein. Often in working veins of this character places are found where replacement has occurred only near one or both wall-forming fractures, and the intervening rock remains partly or wholly unchanged. In the so-called 'true fissure' vein this area of barren country rock between the walls, which is commonly known as a 'horse,' would have to have fallen into the open fissure while the vein was being deposited.

In some instances between the two main fractures, which are the walls for the subsequently formed vein, a series of less extensive fractures are found, and, to the more active replacement along these, the banded structure, which is supposed to be one of the essentials of the 'true fissure' vein, is probably due.

The fissuring or fracturing which permits of the formation of such veins is no doubt deep seated, and whether only one wall or two obtains, to this character of veins could be given the name of 'fissure veins' with some degree of correctness. And, while most of knowledge and opinions of vein deposition is based principally upon comparison to known chemical reactions and to some extent on conjecture, it seems more reasonable to believe that fissure veins are formed by metasomatic replacement along one or between two parallel fractures or fault planes cutting the stratification or foliation of the surrounding formation, rather than by the process of direct precipitation on the walls of a wide fissure or cavity which would probably have to remain open for countless ages for the complete filling to take place. If the latter were true, we would find more fissures partly filled, just as we find areas incompletely replaced in the veins of the former case.

W. Prince Catlin.

Cisco, California, September 24.

[Those interested in the relations of metasomatism to 'fissure veins' will do well to read Waldemar Lindgren's classic paper on 'Metasomatic Deposits in Fissure Veins,' in Volume XXX of the *Trans.* Amer. Inst. Min. Engineers.—Editor.]

A significant feature of the cement industry of the United States is the fact that, though only about 80% of the normal cement-producing capacity of the country is employed at the maximum, there is often an overproduction; yet the exports of hydraulic cement have scarcely exceeded 4,200,000 bbl. in any year, this amount being only about 5% of the total output, not sufficient to take care of the surplus production in a year of great activity.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COKE MANUFACTURED in the United States in 1913 totaled 46,299,530 tons.

RUTILE, titanium oxide, is mined only in Virginia, the output in 1913 being 305 tons, valued at about $49,000.

CYANIDATION of old tailing in Victoria, Australia, is on the decline, and in 1913, 209 plants treated 692,256 tons, yielding 45,397 oz., worth £163,371.

A NEW BEARING METAL, more durable than phosphor bronze, and consisting of 65 parts of copper, 30 of lead, and 5 of tin, has recently shown excellent results.

TWO OR THREE-KEY single-gib tappets are used with stamps up to about 1400 lb. Beyond this weight of stamp it is advisable to use double-gib four-key tappets.

THE THICKER AND STIFFER A TIRE IS, the more motor energy it takes to run it. With four such power-consuming tires on a car, the car performs poorly and consumes great quantities of gasoline needlessly.

BORAX PRODUCTION of the United States in 1913 was 58,051 short tons worth $1,491,530, against 42,315 tons and $1,127,813 in 1912. This came entirely from California. Imports were valued at $18,434.

FUEL CONSUMPTION in 'burning' lime is 1 lb. coal for 1.5 to 6 lb. of lime, with an average of about 3.6 lb. lime. With 1 lb. of coke 4.2 lb. of lime is burned; and with 1 cord of wood approximately 4000 lb. of lime is burned, depending on the kind of wood used.

POTASSIUM CYANIDE worth $81,836 was exported to the United States from Magdeburg, Germany, near where are the great potash deposits of Stassfurt, in 1913, against $146,296 in 1912. The value of potash sold in this district in 1913 was approximately $45,500,000.

SALINITY of Great Salt Lake, Utah, varies from 13.79 to 27.72%; and analyses show 55.99% chlorine, 33.15% sodium, 6.57% SO_4, 1.60% potassium, 0.17% lime, and 2.52% magnesia. Compared with sea water the sodium is higher, but lime and magnesia, especially the former, are much lower.

CAM-SHAFT BEARINGS are generally provided with dust covers to take the place of caps. White metal, or babbit, is also sometimes dispensed with when the vibrations cause fracture of this material. In the latter case the casting is turned to take the cam-shaft, and no antifriction metal is used.

MAPLE-COG BEVEL-GEARS are used in the Hollinger mill, Ontario, according to H. C. Parmelee. The substitution of these for steel has effected a great saving in cost; whereas the steel costs $105 per set and lasts six months, the wood gear costs $25 and lasts the same time. It is silent in operation.

MODERN CLASSIFICATION METHODS are almost confined to the successful issue which has resulted from the adoption of the gravitational plus mechanical, as opposed to the purely gravitational, separation of sand from slime. The former method of classification is especially adapted to tube-mill work, where it is essential that a low and definite percentage of moisture should be maintained in the feed.

ALL COAL contains some sulphur, generally in the form of iron pyrite, from a very small amount to 2 or 4%. When damp, sulphurous acid is formed, which is corrosive to the steel bins which the coal may be kept in at tipples, power plants, or even railroad cars. Where such trouble is experienced, it is found best to line bins or bunkers with a few inches of concrete or cement, the latter put on with a cement-gun.

DYES imported into the United States in the fiscal year ended June 30, 1914, were valued at $9,403,819, of which $7,940,061 came from Germany in the shape of alizarin colors (carmine, green, red, and yellow hues), aniline salts, indigo, and coal-tar colors. The consumption of dyestuffs in the United States is about $25,000,000 per year, and in 1909 the domestic production was $16,428,676, against $10,912,224 in 1904. In this industry is a form of poisoning known as anilisin, caused by fume from aniline dyes.

MINE SAMPLING has been discussed vigorously from time to time. In the *Transactions* of the Canadian Mining Institute, Volume XVI, G. C. Bateman's notes contain the following pertinent remarks: "A number of small samples are better than a few large ones;" "The sample taken over too large an area tends to obscure the mistakes;" "In a multiplicity of samples lies the engineer's safeguard;" "The writer believes in cutting short sections in preference to long ones * * * the slight objection of extra cost for assaying counts for little." The want of consideration of these particulars has long seemed to Victor G. Hills of Denver, Colorado, the weakest point shown in the average mine sampler's practice, according to the Institute's *Monthly Bulletin* for September.

MINING IN THE FAR NORTH*

Operations of Yukon Gold Company

By EMIL EDWARD HURJA

The Yukon Gold Co. operates nine dredges and from 15 to 18 fully equipped hydraulic plants in Alaska and the Klondike. Expectations of Company engineers are that last year's output of $4,427,579 will be materially increased, with working costs much lower than before. Eight of the dredges and all the hydraulic operations are in the Klondike district; one dredge is being operated in the Iditarod district on Flat creek.

Dredge No. 1, a Bucyrus 5-ft., is operating on 96 Below, Bonanza creek; No. 2 and 3, of similar make, on 50 and 67 Below, Bonanza, respectively. Dredge No. 4, a Marion 7-ft., is on 42 Below, Hunker creek; No. 5, a 7-ft. Bucyrus, on 8 Below, Bonanza; No. 6, a 7-ft. Bucyrus, on 12 Below, Gold Run; No. 8, a 7-ft. Bucyrus, on 16 Above, Bonanza; and No. 9, a 7-ft. Bucyrus, on 16, Eldorado creek. No. 7, a 7-ft. Marion, operates in the Iditarod district. Equipment of the 7-ft. boats has been standardized during the past two years, so that buckets, pins and all wearing parts of both the 5 and 7-ft. dredges are now alike. No. 8 and 9 are the only boats having steel hulls.

The Season for 1914

Operation began in 1914 on May 12, and within the week following, all but one of the Klondike dredges began digging. Dredge No. 6, which was dismantled and moved during the winter from Bonanza creek, where the block of ground assigned to it had been worked out, was in operation June 1, on Gold Run creek. The hull was lengthened, as was the ladder and bucket line, because of the greater depth of the ground. On the lower end of Gold Run, where the dredge has started operations, the depth to bedrock is from 35 to 40 ft., becoming shallower farther upstream. The removal of the dredge to Gold Run meant a haul of 55 miles, part by railroad and the rest by sleighs; as well as the construction of 32 miles of high tension transmission line, three miles of secondary line and a sub-station. It is estimated the three miles of Gold Run creek available for dredging contains 4,500,000 cu. yd. of gravel. No. 4 was rebuilt this spring on 42 Below, Hunker creek, after working out the Anderson concession on the same stream. Power was obtained by continuing the lines already on the creek farther downstream.

At the close of the 1913 season the power contract with the Granville Power Co. was canceled, and all the power this season has been obtained from the Yukon Gold Co.'s own power-house at Twelvemile, 30 miles from Dawson. The plant started operation May 9, and the first dredge a few days later. Up to August 4 the operation during 1914 had been perfect, not a single minute's delay being occasioned by any cause. The plant supplies 2000 kw. It was built in 1906. The dredging season will be a few weeks shorter at each end, because the Twelvemile plant closes down during the winter time.

In 1913, the Yukon Gold Co. dredges at Dawson operated 79.6% of a possible dredging season of 184 days. The yardage totaled 5,133,575 cu. yd., which produced $3,343,667 or an average of 65.13c. per cubic yard. The average cost, including depreciation, was 29.53c. per yard. The proportion of frozen ground this year will be considerably less than last year, when 68.4% of the ground worked had to be thawed by steam.

The Iditarod dredge started operating in 1914 on May 1, and since that time, has made good progress. It has worked out the upper end of the Wildcat Association claim and is now digging on the Chicago Association on Flat creek, the suit touching on the ownership of that claim having been decided in favor of the Yukon Gold Co. Water conditions this year have been particularly good; the grade has been reduced from 6 to 2% and the layer of gumbo clay gives no more trouble. Last year the dredge established a world's record. In three days it took out $86,000, with dirt averaging $8.60 per yard. The operation so far this season has shown some four and five-dollar dirt. Power for the dredge is obtained from a 300-kw. steam turbine power plant, which is to be replaced next season by a permanent plant on Iditarod river, 20 miles above the town of Iditarod. Workmen are now preparing the foundations and installing boilers, etc. Only the electric generating equipment of the present plant will be used. The new site for the power plant gives a cheaper price for wood and will reduce the cost of power. Last year the Iditarod dredge worked from May 8 to November 25, handling 496,756 cu. yd., which produced $827,420 in gross gold, at an average value of $1.67 per cubic yard. The cost, which includes depreciation due to the power plant installation, etc., was 64.33c. per cubic yard.

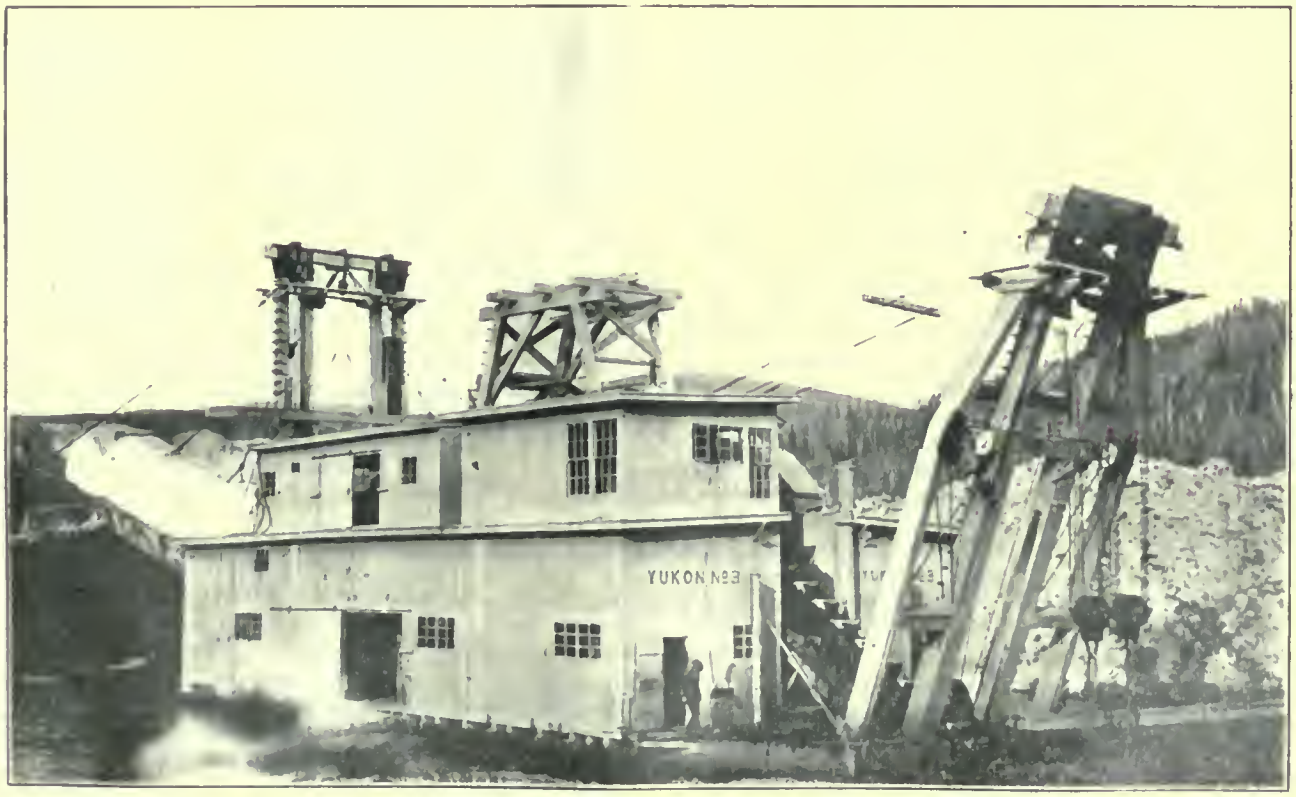
Hydraulic operations of the Yukon Gold Co. in the Klondike are being conducted with from 15 to 18 plants on Lovett, Trail, King Solomon, Monte Cristo, Magnet, and American gulches, as well as Bunker Hill. Sluices with manganese steel riffle bars are used. Giants with either four or six-inch nozzles are used, with the exception of Bunker Hill, where a smaller plant is in operation. Water conditions this season have been particularly good. In 1913, a total of 2,875,952 cu. yd. was handled, producing $256,491 in gross gold. The cost was $278,917, the loss being due to the fact that considerable waste gravel was removed to prepare ground for the present season's work. By the end of the present season, Dredge No. 3 will have completed its work on Bonanza creek, and plans for its dismantling and removal to another part of the Company's holdings are now being considered by engineers. Prospecting work by the Company is conducted with a special drill, the work of the engineering corps, and three Keystones. They are kept at work continually ahead of the dredges, proving up the ground and laying out the course for the boats.

Experimental Work on Thawing

Of special interest are the experiments being conducted by the Company with a view to deep thawing. Thawing has been necessary to keep ground opened up ahead of the dredge, but previous attempts have been confined to gravel deposits not exceeding 40 ft. in depth. About June 15, work was started on the lower end of Gold Run creek, where the Company owns considerable ground, to determine whether deep thawing would be feasible. A special drill, used without casing, is in service. Special points also are being tested, and it is expected that before the end of the season the results of the experiments will be known. The ground is over 50 ft. deep, contains gold

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29; 'The Koyukuk Mining District,' September 12. Mr. Hurja in subsequent letters will give full accounts of present conditions in each of the great producing districts of the Far North.—Editor.]

FOUR HENDY GIANTS AT WORK, LOVETT GULCH.



DREDGE No. 3, A BUCYRUS BOAT, ON 67 BONANZA CREEK.

in workable quantities, but because of the inability to thaw it properly, is being left unworked. If the deep thawing proves feasible, immense bodies of dredgable gravel will be opened.

Engineers of the Yukon Gold Co. are investigating properties in different parts of Alaska. Several parties are in the field continually. Options taken on the entire length of Sixtymile creek will expire next spring. A preliminary examination was made last winter; work being discontinued with the arrival of spring. It is probable that more prospecting will be done next winter.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MANILA, PHILIPPINE ISLANDS

THE DREDGING INDUSTRY. NOTES ON THE MALAGUIT, MAXIMELO, PHILIPPINE DREDGES, GUMAOS, AND UMARI GOLD COMPANIES. —BINABAY GRAVELS.—MINES IN MASBATE.—LARGE DEPOSIT OF IRON ORE UNDER EXAMINATION.—OIL, COPPER, LUMBER, AND REVENUES.

Gold dredging at Paracale, Camarines province, continues with unabated activity.——The Malaguit Dredging Co., with its new Yuba Construction Co. dredge, which began operation on Malaguit river in March 1914, has declared an initial dividend of 2½%. Two of the Australian companies have declared small dividends during the last month. The Maximelo Dredging Co., which took over the property of the old Stanley-Paracale company at the head of Paracale river, is said to have paid 30% in dividends within the past 18 months. Frank D. Ingersoll, managing director of the Malaguit Dredging Co., has sailed for the United States in the interests of his Company. A. F. Shores, a mining engineer from Melbourne, Australia, is at Paracale at present, going over the holdings of the Philippine Dredges, Ltd., of which he is secretary. J. V. Lafferty, to whom the success of the Maximelo dredge is due in large measure, is in active charge of operations as dredgemaster.

The Gumaos Placer Co., operating a single dredge, recovered 1679 oz. of bullion during July. This is one of the best runs the boat has made, the record monthly run of something over a year ago having been 2085 oz. The gold from the Gumaos claim is about 875 fine. The extension for the Gumaos digging ladder, sent out several months ago by the New York Engineering Co., which built the dredge, has not yet been put in place, although it is stored on the claim. Soon after beginning work, the dredge got into ground where it could not reach bedrock, and it was decided to extend the digging-ladder. Subsequent operation has shown, however, that over the larger part of the claim, the present ladder, dredging to a depth of 52 ft., is adequate, and as the work is planned it will be some months, according to Mr. Kane, the dredgemaster, before deep ground is again encountered. Until it is needed, therefore, the extension to the ladder will not be added.

The Umari Gold, Ltd., an Australian company, which has leased ten 64-hectare (160 acres) claims on the Umari river, in a little-known region on the eastern coast of Luzon, well to the north of Paracale, has begun the process of dredging up the river to the first claim, a distance of about one mile. The dredge is of Australian design, with a steel hull and 7-cu. ft. close-connected buckets. According to the prospectus of the Company, 11 three-inch test-holes were put down on the claims which it is proposed to dredge, by its engineers, H. Hardman and Herbert Park. Depths ranged from 8 to 26 ft. (bedrock was apparently not reached in all the holes), and assays were from 20c. to $1.09, averaging about 75c., per cubic yard. A considerable quantity of black sand is obtained, which, after panning, is said still to be worth about $60 per ton. The test-holes appear to have been put down over an area only large enough to insure returns on the investment required, but the examining engineers believe them to be representative of practically the whole area of the lease, about 1600 acres.

R. H. Humphreys, a mining engineer from Berkeley, California, who is in the Philippines in the interest of A. Heise, a locally well known mining man, recently went to Umari to test some claims adjacent to those held by the Umari Gold, Limited.

Renewed interest has been awakened in Mindoro placers by the discoveries of prospectors on the Binabay river, in the northern part of the island. For several weeks immediately before the rainy season started, there was quite a rush to the new district, and numerous claims have been staked. Baco river, into which the Binabay empties, has been explored previously below the mouth of the latter stream, with only fair results; but the promising new finds were made in a less accessible country farther inland. The gold from Binabay river is coarse and well rounded, the latter characteristic being in marked contrast to the sharpness and frequent crystallinity of the Paracale gold. Some of the Binabay nuggets weigh as much as 10 grams, worth about $5.

MAP OF NORTHERN PART OF THE PHILIPPINES

J. L. Jeffcoate, an Australian capitalist, who is inquiring into possible mining investments in the Philippines, is said to have become interested in the Binabay field, and an engineer will probably be sent in to test some of the claims as soon as the rains will permit, about October. It appears that where the richest finds were obtained, the deposits may be worked by hydraulicking rather than by dredging, because of the steep gradient and small volume of the streams.

It may be noted that the vicinity of Binabay river is not a great distance from the intersection of two prominent tectonic lines in the Philippine geologic structure. One of these lines runs west-northwest along the north coast of Mindoro and through Lubang Islands, which have long been known to consist in large part of schist and quartz. The other line, trending southwest from Taal volcano on Luzon, passes through northeastern Mindoro and is continued to the southwest in the axis of the island of Palauan. The established gold-producing district at Aroroy, Masbate, it has been pointed out, is similarly situated near the intersection of two main tectonic lines.

Three lode-gold properties are now operating in Masbate with a combined milling capacity of nearly 300 tons per day; the average ore is reported to run from $10 to $15 per ton. The Colorado mine has been in uninterrupted operation for nearly three years, while the Syndicate and the Keystone began treating ore since the first of the current year.

The Headwaters mine near Baguio, Benguet, has passed into the hands of Mr. Noble and associates of Hong Kong, and M. Eissler, a French mining engineer, who is well known in the Orient, has been engaged to determine the advisability of undertaking the development work which is required to secure an adequate supply of ore for the mill.——The Benguet Consolidated property, also near Baguio, has acquired sufficient capital to erect a small mill to replace the one which was destroyed by floods several years ago. C. M. Eye, who built the old Consolidated mill, as well as the present mill at the Colorado mine in Masbate, has been retained for the design and erection of the new mill, and construction will be started immediately. [Mr. Eye left San Francisco for the Philippines two weeks ago.—Editor.] The Benguet Consolidated is generally considered to be one of the best properties in the Philippines, and much interest attaches to the news that it will renew operations. A. W. Beam, the secretary of the old Company, has been active in effecting its reorganization.

An apparently large and hitherto unrecognized deposit of iron ore in Surigao province, Mindanao, has been brought to the notice of the mining public by H. F. Cameron, department engineer for Mindanao and Sulu. The extremely red soil along the eastern coast of Mindanao attracted the attention of Mr. Cameron because of the striking resemblance it bore to the Nipe bay, Cuba, iron ore, with which he had become familiar several years ago. He took several samples and submitted them officially to the Bureau of Science for analysis. The analyses showed that the ore was indeed very similar in composition to the Cuban ores. The Surigao ore is a clayey red limonite containing about 59% of iron when dry; no sulphur or phosphorus, but like the Mayari and Nipe Bay ores, it carries small percentages of chromium. Some agglomerating or nodulizing process will be required as a preliminary to smelting, since the ore in its natural state is very fine. It appears that the ore occurs as a surface decomposition product of basic rocks, and, according to Mr. Cameron's estimates, it covers an area of about 40 square miles, varying in depth up to about 40 ft. Owing to the industrial importance of so vast a deposit of iron ore as this one appears to be, the area over which it extends has been reserved by executive order from mineral location, until the government can be informed through surveys by the Bureau of Science as to its actual extent and value.

Copper ore containing a considerable proportion of metallic copper has recently been found by prospectors in Zambales province. Although a good deal of copper has been brought in from Zambales, no metallic copper had previously been noted in the specimens.

A trace of petroleum was encountered at a depth of about 1100 ft. in drilling an artesian well at Anda, Pangasinan. The well went deeper into salt water. Anda is in a region from which oil has been reported several times, but this is the first authentic verification of its occurrence there.

Number 3 of Section A of the current volume of *The Philippine Journal of Science* contains a paper on the iron ores of Bulacan province by F. A. Dalburg and Wallace E. Pratt, with a microscopic study of the ores by F. T. Eddingfield. The Bulacan ores are hematite and magnetite in intimate mixture with quartz as the typical gangue material. They are found in proximity to limestone usually, and rarely veins of the ore occur in limestone. The deposits form detached lenses along the base of Miocene sedimentaries and the underlying older igneous base. The walls are replaced in part by ore and consist of a decomposed green aggregate of complex basic silicate minerals, a material probably somewhat analogous to the *skarn* of the Scandinavian geologists. The Bulacan ores are considered to be the result of contact mineralization following the intrusion of igneous dike rocks; much of the ore appears to be a replacement of limestone and other intruded rocks. There is no development work which affords a basis for estimating the quantity of ore available. Purely upon outcrop measurements it is estimated that at least one million tons is contained in the largest orebody.

In response to the advertisement of the United States Navy Department for 1,500,000 teak decking logs, a local lumber firm has submitted an offer of 500,000 ft. of *yacal*, a Philippine wood resembling teak, which is regarded as the equal of teak for construction purposes. This is the first time that such offers of Philippine woods have been made to the navy, according to a *Daily Consular Report* from Washington, D. C.

A *cadastral* (property valuation) survey of the land within the city of Manila has been started under the direction of the Bureau of Lands. The cost is estimated at $83,000 and time to be taken at 30 months.

Total customs revenues of the Philippine government for the six months ended June 30, 1914, were $3,169,761, against $3,448,670 in the same period of 1913. The decrease is due to the removal of the export tax.

WASHINGTON, D. C.

Bills in Congress to Suspend Assessment Work on Mining Claims.—Alaska Coal Bills.

New mining legislation in Congress to meet a purported urgency growing out of the European war would suspend the requirements of $100 worth of labor upon all mining claims of whatever nature. There are two such resolutions, one by Senator Thomas of Colorado, and the other by Senator Smoot of Utah. A third is by Senator Shafroth of Colorado, which would suspend the requirements of $100 worth of labor upon each mining claim bearing carnotite ore, from which radium is derived. The suspension is applicable only for the year 1914. The preamble asserts that this relief ought to be shown to radium miners, whose ores have been greatly reduced in selling value through the restriction and limitation of the market for carnotite ore because of the European war. A proviso in the resolution is that the claimants of carnotite mining locations shall file for record in the office of the county clerk and recorder of the county in which the mine is situated, on or before December 31, 1914, a notice that he, or she, or they claim the benefit of this act and in good faith intend to hold and work the claim. The Thomas and Smoot resolutions are being opposed on the ground that to grant the suspension would greatly injure many miners who are employed by claimants, by depriving them of work. Thus more would be injured than benefited. This point is not thought to apply to radium mining, as the market for radium has practically disappeared.

The Senate, on September 26, passed the Alaska coal leasing bill, and as there have been amendments to the House bill,

the bill goes into conference, from whence it may come out in some new form, probably with modifications of both bills as they passed the respective houses. There was no roll-call on the vote taken to pass the bill, a call being omitted for fear a quorum might not develop. In the opinion of Senator Borah, of Idaho, who was opposed to the bill, the stipulations in it are such that Alaska will be no nearer development in its coal resources twenty years hence than it is today. Private capital will not care to enlist in the enterprise. The Secretary of the Interior, Franklin K. Lane, is quoted as having said that he is willing to try the leasing system "on the dog," to see how it will work out. The House also has passed the bill for the exploration of coal, etc., which now goes to the Senate.

NEW YORK

COBALT NOTES, KERR LAKE REPORT, NIPISSING AND CROWN RESERVE OPTIONS.—COPPER BUSINESS AND EXPORTS.—COPPER DIVIDENDS.—INSPIRATION AND ALASKA GOLD MILLS.

The Kerr Lake Mining Co. has made its report for the year ended August 31 and shows a net profit of $620,786, as compared to $769,176 for the preceding year. The output of silver was a little less, being 1,828,424 oz., compared with 1,855,495 oz. in the preceding year. The average cost of production, however, showed a marked increase, being 24.86c. per ounce, against 18.30c., the difference being due to the increased cost of shipment and treatment, this being 11.61c. per ounce, compared with 5.55c. in 1913. Ore reserves remain practically the same. The manager, Robert Livermore, estimated them at about 5,698,700 oz, and then stated that the appearance of the bottom of Kerr lake in the vicinity of the Maine East and Fleming veins, indicates that a large tonnage of milling ore can be obtained there, though this is not included in the estimate of ore reserves. Of the total silver production, approximately one-third was recovered from low-grade ores averaging 33.83 oz. per ton milled by the Dominion Reduction Co., Ltd., at Cobalt. The Kerr Lake company had no difficulty in earning the $614,000 which it paid in dividends last year, and its position seems to be excellent.——The Nipissing will not exercise its option on the stock of the McIntyre mine, the reason being that a careful study of the records of the McIntyre indicated to the Nipissing management that they would not be justified in paying the price demanded. The estimated net profits of the Nipissing Mines Co. for August are given as $136,778, against $131,847 in July.——The Crown Reserve interests have taken an option on the North Thompson claim at Porcupine. This lies between the Vipond and the Porcupine Crown, and it is calculated that one of the veins of the Porcupine Crown dips into this ground. The Crown Reserve once before had an option on this claim, but allowed it to pass into the hands of the Von Polenz syndicate, instead of taking it up.

The copper market after being fairly strong last week became dull again, and there is little buying at present. Domestic consumption seems to be fairly satisfactory, and the treasurer of the Rome Wire Co. is quoted as saying that the Company's orders during August were good, and that in most departments the plant is running full time. It is characteristic of the copper market that buying is somewhat spasmodic, so there is hope that it will soon strengthen again. Shipments abroad are markedly restrained by the action of the Allies, who have declared that copper is a conditional contraband, and that shipments to Holland are undoubtedly in large part destined to pass on to Krupp's gun factory at Essen. Some copper at Rotterdam has already been transferred to England, and the Holland America Steamship Co. now refuses to take shipments of copper consigned to Holland. There is no ground for protest on the part of the United States government, as the British government has paid for the copper which it diverted from Holland to England. The result of the situation will be, though, that about the only copper that will be shipped abroad is that consigned to England and France. As considerable amounts have been going to Rotterdam, this will have a marked effect on export movements. It may be that the producers here will have to reduce their output even more. The Shattuck Arizona Mining Co. has deferred its October dividend, recent payments having been at the rate of $1.50 per year.—The Calumet & Arizona and the Superior & Pittsburgh have also suspended payment of their dividends.—— Within a fortnight the Miami company will have to consider the dividend question also.——The management of the Inspiration reports that the mill will not be started until the first of February, and then only at half capacity. It was originally expected to have the full 10,000-ton mill in operation before the end of this year, but with the present condition of the copper market it is not wise to produce at full capacity.

The Alaska Gold Mines Co. announces that the milling plant will be operating by the first of January, and it is hoped to have it going before Christmas. This is the first 1000-ton unit, and its contribution to the gold output of the country will be very welcome just at this time.

Columbia University started its academic year on September 23. A record registration is announced in spite of fewer foreign students. The New York University has opened for the year with a total of about 7000 students. Princeton University's 168th year commenced on September 25.

BUTTE, MONTANA

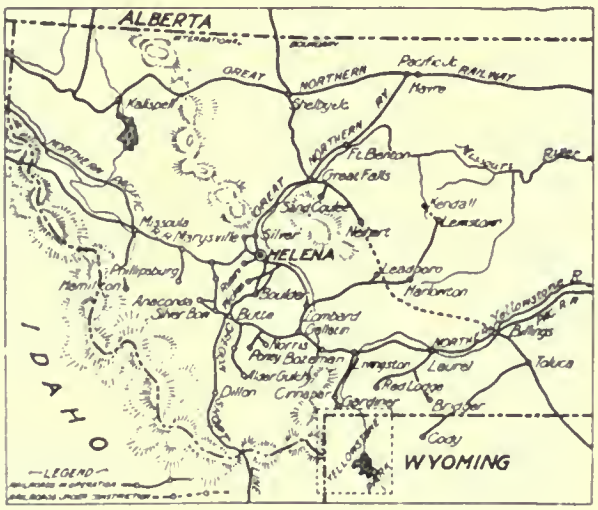
UNDER MILITARY RULE BUTTE IS QUIET, NOW THAT THE LABOR AGITATORS HAVE FELT THE ARM OF THE LAW.—POSITION OF THE MINING COMPANIES AND THE WHOLE STATE.

About the only evidence that a stranger in Butte would have that conditions were not normal would be the presence of the militia. No crowds gather on the streets; there is a pleasing absence of soap-box oratory; and business is carried on as usual. But about the county court-house a decidedly military atmosphere prevails. Numerous sentinels guard the approaches of the building on each side, and no one is permitted within that block without a pass granted by the military authorities. Rapid-fire machine-guns are stationed in front of the court-house, back of the court-house, and at the head of Montana street, and possibly at other points not known to the general public. Squads of militia may be seen at almost any time of the day performing their evolutions or *en route* to the target-practice grounds below the city. Military courts have been active in suppressing disturbers and violators of the law. The judgments of these courts are prompt and severe, much to the satisfaction of the law-abiding members of the community. Many agitators from other mining districts throughout the West have been congregating in Butte during the past year, openly insulting the flag, and defying the law. All unpatriotic action and talk by these men are receiving summary punishment at the hands of the military tribunals. A barber who refused to shave a soldier was promptly thrown into jail; a ruffian who abused a citizen who was associating with soldiers off duty was given a severe jail sentence; a city socialist official who showed open disrespect for the soldiers and their uniforms was also sent to jail; a man who was carrying concealed weapons without permission, and who was assisting a law-breaker to escape, has been sentenced to 4½ years in the state penitentiary. The socialist mayor of the city and the county sheriff are under trial for failure to utilize the city and county peace officers in quelling the riots last June. The immediate effects of these attempts to restore order and lawfulness are good, but notwithstanding, the thinking men of the community are inclined to believe that Butte is now

resting on a sleeping volcano which may break out at any time and throw things again into turmoil.

The mining companies have been endeavoring to avoid becoming involved in these difficulties as much as possible. They are working all the men which market conditions will justify, and are showing their employees all possible consideration. It would seem the agitators have chosen a very unpropitious time to create these unsettled conditions, as the copper mining companies are working under great disadvantage anyway, because of the European war. If the local labor situation becomes any more strained than it is now, no one could blame the copper companies for closing down the mines entirely until the I. W. W. and other agitators should be starved out of the place. The mining companies in Butte are still employing about 8000 men, giving a preference to married men and older employees, and giving nearly all of them an opportunity to work five shifts per week.

Because of fear of explosions and other violence at night, the military authorities have established searchlights on various high buildings which play their rays throughout the city all night. Saloons were closed entirely for a while, but as quiet continued to prevail, and as conditions became ap-



MAP OF SOUTHWEST MONTANA

parently more normal, they have been given longer and longer hours of opening, until now they close at midnight and reopen at 7 o'clock in the morning. Several saloonmen, who have attempted to keep open in violation of the law, have suffered summary punishment. Their saloons have been entered by the militia, and their liquors have been carried into the street, kegs burst open, bottles broken, and the 'fiery liquid' allowed to flow down the gutters into the sewers. In addition to having their property destroyed, some of the more open violators of the closing law have been either fined heavily or sentenced to prison. It is a relief to the law-abiding people of the community to find that the laws can thus be really enforced, and that summary justice is being dealt out to the criminals.

Of course, the general panicky situation throughout the country because of the European war has reflected harmfully on the mining districts of the state, many properties which required the expenditure of further money before becoming self-supporting, have been closed down, and many other properties which were dependent upon smelters which have been closed, have had to suspend also. Taking it all in all, however, Montana seems to be standing up under these troublous conditions as well as, if not better than, most of the Western states. The state's crops are exceptionally large, and are bringing high prices, and the demand for its horses and cattle is unabated.

TORONTO, ONTARIO

OPERATION OF THE ACME, HOLLINGER, JUPITER, SCHUMACHER, VIPOND, AND NORTH THOMPSON AT PORCUPINE.—LA ROSE TO BE FURTHER PROSPECTED.—COBALT LAKE MINE.—RICE LAKE GOLDFIELD.—ALBERTA COAL MINES.

A large six-compartment shaft is being sunk at the Acme property at Porcupine, owned by the Canadian Mining & Finance Corporation. It will be used for hoisting ore from the Hollinger, Acme, and Miller-Middleton mines, and is expected to effect marked economies. The shaft, which is about 1000 ft. from the present Hollinger shaft, will be put down to 1300 ft., with levels at 425 and 800 ft. The Hollinger is now employing 900 men, and the number will be largely increased when the additions to the mill are completed, and in operation.

The option held by the McKinley-Darragh company of Cobalt, on the Jupiter mine, which expired September 18, has been extended for a term of three months, the prospective purchasers having been encouraged by the later results of development. Operations by the McKinley-Darragh are to be continued. S. W. Schumacher, the owner of the Schumacher mine, announces that he will soon erect a mill. Sinking has been suspended, but the veins opened above the 300-ft. level will be developed. The scheme adopted some months ago for financing the Vipond has fallen through, but the mine has been placed on a paying basis with funds raised on the guarantee of Henry H. Ward, president of the Porcupine Vipond company.

The Little Pet recently produced gold to the value of about $4000 as the result of a 20-day run of a 2-stamp mill. A short but rich ore-shoot has been opened on the 50-ft. level.

The La Rose directorate has decided to make an effort to secure a new lease of life for the property, which has nearly ceased to be productive. Instead of abandoning further operations, and distributing the large surplus among the shareholders as was proposed, extensive exploration work is being undertaken in the hope of discovering new deposits. The force has been increased by 40 men for this purpose. This course was recommended by Rolla B. Watson, the general manager, and Percy A. Robins, manager of the Hollinger, after a close examination of the property. At the Cobalt Lake some good ore has been found in the conglomerate at 390 ft., in a winze put down from the 226-ft. level. The mill has been running to capacity all the year, and the production for 1914 will exceed that of last year.

The Rice Lake gold area of Manitoba is attracting renewed attention on account of recent rich finds, and prospectors from Ontario and the Western states are flocking in. The Independence Mining Co. has bought a rich claim on Gold Lake, 1½ tons of ore from which yielded $260 in gold, with a low recovery. The Company is arranging for the erection of a 5-stamp mill with a cyanide plant. In the meantime it will ship picked high-grade ore to Montana for treatment.

The coal mining industry of Alberta has been benefited by new railroad rates and regulations which went into force on September 1. The Canadian Coal & Coke Co., controlling several Alberta collieries, is preparing to enter the Winnipeg market, and supply the country to the west as far as Prince Rupert. The Pacific Pass colliery, owned by this Company, has an output of 700 tons per day, its capacity being 2000 tons. The present force of 150 men is to be at least doubled during the winter. The staff of the St. Albert mine is also to be increased as the demand warrants. The Yellowhead Pass Coal Co., which has been producing 200 tons per day, will increase its output to 600 tons for the supply of the domestic market in Edmonton.

The Canadian government has extended all oil and gas leases for one year without rentals, on account of the depression due to the war.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

Mine taxation and mining investments will be the principal subjects discussed at the meeting of the American Mining Congress at Phoenix, on December 7 to 11, according to the announcements of the secretary. Invitations have been sent to 4000 Western mine operators.

A fine exhibit of mine ores and products is to be shown at the Arizona State Fair at Phoenix on November 9. J. C. Goodwin is in charge of the mining department. The Copper Queen, Calumet & Arizona, and United Verde have sent excellent samples.

Cochise County

The new experimental plant of the Copper Queen company is working at one-fifth capacity, or 30 tons per day. The concentrate output from this is six tons, and the recovery is 75%. As the vanners are only saving about 25% of the metal in the slime, tests are to be made to improve this department. Oil flotation is being tried in the plant. At 800 ft. in the Gardner shaft of the Copper Queen mine; a good body of lead-silver-gold ore has been opened, galena predominating. The new central tool-sharpening shop and sawmill at this shaft are nearing completion. Two Leyner drill-sharpening machines are to be used. The Company is making a collection of ores of the district for the exposition at San Francisco. Albert Watkins, thoroughly conversant with the ores, is in charge of this work.

Gila County

Very rich silver ore has been opened near Globe by William Pohl.

Mohave County

The Cedar district is said to be one of the promising fields of northern Arizona, and prospecting has shown good deposits of copper-gold-silver, and molybdenum ores. Here the Arizona-Venture Corporation owns five groups of claims, and good ore has been opened.——Near the Grand Cañon, and 90 miles northeast of Hackberry, is the copper mine of W. B. Ridenour of that place, and which is producing over 50% ore from a narrow vein.——Lessees at the Grand Gulch mine recently shipped a carload of 43.2% copper ore to Salt Lake City. This ore was from a raise above the 200-ft. level. The deposit in this mine is circular in form.

CALIFORNIA

The magnesite production of this state should be increased, according to the U. S. Geological Survey. Imports into the United States in 1913 were 172,591 short tons, of which 163,715 tons came from Austria-Hungary, the balance from Greece. The ore was calcined at Hamburg and Rotterdam before shipment to this country. There are numerous extensive and high-grade deposits in California, especially in Santa Clara and San Benito counties. Most of them are somewhat remote from railroads, so only the small deposits near the lines are being worked.

The following circular has been sent to a number of mine operators in the United States: It is planned to hold a national mine rescue and first-aid contest in San Francisco some time during the spring or summer of 1915. This contest will be conducted under the auspices of the U. S. Bureau of Mines, with the coöperation of the American Mine Safety Association. Assurances have been received that teams from a number of the Western states will enter for the meet. The department will be glad to know whether it is probable that a team from your mine or from your district can enter. There will be no expense connected with the entrance of a team, except for first-aid supplies, and for traveling expenses of the men. Replies or inquiries should be directed to H. M. Wilson, Bureau of Mines, Pittsburgh, Pennsylvania, or to H. M. Wolflin, Underwood Building, San Francisco, California.

The tentative itinerary for rescue-car No. 5 in California is as follows: September 28 to October 5, Jamestown; October 6 to 20, Stanford University; October 21 to November 4, Berkeley; and November 5 to 15, Kennett, all in California.

Amador County

The first return from the Plymouth Consolidated has been published in London as follows: stamp-mill operating in August, 696 hours; ore crushed, 9157 tons; value of gold and concentrate, $30,750. The feed was partly from low-grade dumps, and a good deal of gold was absorbed in the plant. W. J. Loring states that everything is satisfactory.

Improvements are to be made to the Original Amador mill at Amador City, and two 8-ft. by 36-in. Hardinge mills have been ordered to increase the tonnage and recovery.

Nevada County

In the Phoenix mine adjoining the Oustomah, a rich shoot of ore 6 in. wide has been cut. It is probably an extension of the Oustomah vein.——The North Star company is actively working its Champion mine and mill.——At the Union Hill mine, recently acquired by a new company, the shaft is to be sunk much lower. A. D. Cox, of Goldfield, is in charge.

Shasta County

The Heroult electric smelter started making ferro-manganese on September 30.——Los Angeles people have taken the Dry Slide gold mine under a bond for $25,000, and will start considerable new work. The Mammoth Copper Co. is now employing from 400 to 450 men.—On October 1 a fire destroyed property at Kennett worth $80,000, covered by $30,000 insurance.

Siskiyou County

(Special Correspondence.)—Work has been resumed at the Oom Paul mine, near Oro Fino, recently taken under lease by A. C. Renfrew. A new shoot has been opened, reported to assay about $20 in gold per ton.——Ore has been opened in the Little Maggie mine, near Grouse creek. The discovery was made in a rise from the lower adit, and the small mill will start crushing as soon as a concentrator has been provided to handle the sulphides. Simon Barrendun is managing owner.——The Siskiyou Mines Co. is arranging to install new flumes and sluices at its hydraulic mines at South Fork. Considerable prospecting has been done the past summer, and the outlook is favorable for a good season.——Several placer mining companies in the western part of the county are preparing for the next season, and are awaiting a heavy rain to start preliminary work. Stoping of good ore is going on at the quartz property of Cory & Messner on Sugar creek. The shoot was discovered a few weeks ago, and the mill will start operations as soon as sufficient water is available.——San Francisco people, headed by J. M. Schuman, a mining engineer, are examining claims in the Sawyer's Bar district. Eastern people are said to have taken an option on the Sugar Hill quartz mine on Fox creek. Under the management of Nickerson & Werst the property has recently developed excellently. A promising vein was recently intersected and is

improving.——F. Welch and associates have started work on two quartz claims near Yreka, owned by Michael Wacker. A cross-cut adit is being driven to cut the vein which has yielded rich ore.——Work at the Cub Bear mine continues to open good ore, and it is probable a small mill will be erected next spring. The vein has widened from 16 to 20 in. with a good milling grade of quartz. Charles Ritz is superintendent.——Recent work at the Big Cliff mine, near Etna Mills, has been of such encouraging character that a small stamp-mill has been acquired and will be immediately installed. H. B. Wintering is manager.——Lessees are opening good ore in the Osgood property, near Yreka. The mine is equipped with a small mill.

Etna Mills, September 27.

TRINITY COUNTY

The Trinity Consolidated company has been doing a great deal of prospecting and other work during the summer, and preparations are being made to sluice a large gravel deposit near the Union Hill mine.——A Keystone drill is prospecting gravel in ground bonded to T. R. Louble, at the mouth of Eastman gulch.——Sampling ground on the Paulsen area, west of Lewiston, is nearly finished.

COLORADO

GILPIN COUNTY

The annual meeting of the St. John Mines (Colorado), Ltd., was held in London on September 14. The directors had decided to retain, if possible, the greater part of the Revenue Tunnel properties under option to the Company, selling only tunnel rights and certain of the less accessible claims, and the whole of these arrangements were on the point of completion when the European war upset all finances. All negotiations, both for the necessary funds and for the sale of tunnel rights, have had to be abandoned for the present. The directors, however, had reason to believe that Mr. Platt, the manager at the mines, would be able to make arrangements whereby the benefits of this option would ultimately be secured for the Company, but it was impossible at the moment to assert this definitely. From the St. John mines a shipment of 150 tons of silver-lead ore assaying $6 per ton, was made; but the smelters were unwilling to settle for further shipments until the metal markets were normal. The mine is shut down for the present. The directors recognized the wisdom of this step, but had to bear in mind that, pending the payment of the balance of between $2000 and $3000 of purchase price payable next January, they had contracted with the vendors to work 200 shifts per month at the mines. In order to close down it would be necessary to pay off this balance and all the local expenditure to date. In these altogether exceptional circumstances the directors would be obliged to raise a small temporary loan to enable them to meet current requirements and resume production as soon as possible.

LAKE COUNTY (LEADVILLE)

Apart from the general depression, a great deal of work is being done around the Leadville mines. The Iron Silver, Yak tunnel, Wolftone, Colonel Sellars, New Monarch, Dinero, and others are working full time.

The Down Town Pumping Co. is trying to start its unwatering scheme by the beginning of 1915. On account of the war, the firm of Sulzer Bros. in Switzerland is unable to supply the pumps contracted for, so bids are being taken from American machinery people. Work will soon be started on buildings for the equipment.

The Western Zinc Mining & Reducing Co., which controls the new zinc smelter here, has decided to resume operations. E. J. Jones is now in charge, replacing A. B. Augustine who has left the Company.

The Connors lease is producing 50 tons of 7 to 10-oz. gold ore per month, and shows no sign of cutting out.——Lessees at the Kyle portion of No. 7 level of the Jonny have opened another shoot.——The Big Four is producing good ore steadily.

TELLER COUNTY (CRIPPLE CREEK)

According to estimates of *The Cripple Creek Times*, the September output of the district was as follows:

Plants.	Tons treated.	Average value.	Gross value.
Golden Cycle	28,000	$20.00	$560,000
Portland (Colorado City)	11,000	19.50	214,500
Smelters	3,860	55.00	212,300
Portland (Cripple Creek)	18,960	2.05	38,680
Stratton's Independence	11,868	2.00	23,736
Colburn-Ajax	4,450	6.50	28,925
Wild Horse	1,250	3.10	3,875
Kavanagh-Jo Dandy	1,700	2.15	3,655
Gaylord-Dante	1,100	2.00	2,200
Isabella	1,000	2.00	2,000
Neville-Free Coinage	200	6.00	1,200
Total	83,388		$1,091,071

Dividends have been paid by the Golden Cycle and Portland, the former the regular monthly of 3c., and an extra one of 2c. per share, totaling $75,000; and the latter 3c. per share, equal to $45,000. A new club-house and locker room for Portland miners is being erected. It will consist of lounging rooms and complete changing facilities.

The new mill of the Vindicator Consolidated is nearly finished. It is to treat ore from the mine. Dumps on the surface containing about 1,000,000 tons will be held in reserve.——A cyanide plant of 50-ton capacity has been planned for the Jerry Johnson mine by the lessee, Frank Caley. He has a lease up to January 1, 1919.

IDAHO

LEMHI COUNTY

(Special Correspondence.)—The Rabbit Foot Mining Co.'s gold mine and stamp-mill resumed work on September 1. They are on Silver creek, and prospects are good.——Work at the Musgrove mine and mill is at full capacity. All machinery is driven by the Company's water-power. R. L. Edwards is manager.——On gold claims owned by J. B. Hastings and others at Yellow Jacket, 50 miles west of Salmon, two shifts of miners have been started. Winter supplies are being taken into the camp.

CYANIDE MILL OF MUSGROVE MINING CO., NEAR SALMON, IDAHO.

Salmon, September 12.

SHOSHONE COUNTY

It is reported that 3 ft. of galena, containing up to 40% lead and some silver, has been cut at 600 ft. in the National copper mine at Mullan.——St. Paul and Milwaukee people are advancing money to continue development of the Coeur d'Alene Silver-Lead company's 12 claims near Mullan. Charles J. Heidenreich is general manager.

MICHIGAN

Houghton County

Large shipments of copper are being made from the district by rail and steamer, the Calumet & Hecla sending out 1200, and Copper Range 800 tons last week.

The rock in which the ore is found in the Calumet & Hecla company's White Pine mine is neither an amygdaloid nor a conglomerate, but a gray and brown sandstone of the upper Keweenawan. The copper is in small particles, and fills in the spaces between the sand grains. The structure of the property is complicated, on account of the displacement of the lodes by faults, and new problems in mining are constantly being met. It is reported that the sandstone contains nearly 100 lb. of copper per ton. The average for the Michigan copper district is about 20 lb. Considering the reported richness of the sandstone, and the estimated mill recovery of over 80%, the success of the White Pine appears a certainty.

On account of financial conditions created by the European war, the Cleveland-Cliffs Iron Co. announced further curtailment, beginning October 1. Shipments this year have been low, with the result that the stock-piles are unusually large. The further decrease means the closing of the Salisbury mine at Ishpeming, the Maas at Negaunee, and the new Mackinaw and Gardner in the Gwinn district. About 400 men have been deprived of employment. The construction of the Jones furnace of the New Process Metals Co., at Marquette, is now nearing completion. It is expected that by November 1 the plant will be ready for operation. Low-grade manganese ore from the Cuyuna range of Minnesota will be used to test the furnace.

MISSOURI

Jasper County

The Duenweg Zinc & Lead Co.'s mill is to be moved to the M. R. Tidwell land north of Commerce, Oklahoma. It will have a capacity of 250 tons per day when overhauled. Good zinc-lead ore has been opened in the Tidwell lease. T. F. Lennan is manager.——Drilling has cut lead ore from 70 to 120 ft. depth, on the west side of the Neosho river, northwest of Miami.

MONTANA

Silverbow County

On October 7, at Butte, committees representing the United Mine Workers of America and the Western Federation of Miners, met to discuss plans of amalgamation. Adam Wilkinson of Montana, Robert Harlan of Washington, and Frank Farrington of Illinois, members of the executive board represented the coal miners. Dean W. Selfridge, J. W. Rankin, and Joseph Gorman represented the Federation. The plan most likely to be accepted is the merging of the Western Federation into the United Mine Workers, the Federation giving up its name. The combined membership would be 550,000. It is expected that the conference and its results will have a strong influence on the Butte trouble. The two organizations now have interchangeable cards. If they decide on a plan of amalgamation, it will have to be submitted to a referendum vote of the membership of both unions for ratification. The committees will probably recommend some disposition of the headquarters of the Western Federation at Denver, in case a merger scheme is worked out. A member of the executive board of the Butte Mine Workers Union has stated that the subject of uniting the Western Federation of Miners and the United Mine Workers had been brought to their attention, but that no definite action of any kind had been taken. The question has been agitated among the members of the mine workers, and, according to him, there has been 'wire pulling,' but the matter has never been given any official recognition. A report that arrangements had been made for the executive board to meet with a committee of the United Mine Workers and the Western Federation, on October 6, was denied. Governor Stewart was unable to attend the meeting of the Butte Mine Workers, to deliver his address, but it is hoped that he will be able to talk to them in the near future.

At the Butte-Duluth, another set of 20 by 54-in. Doty rolls is to be installed to crush ore for the leaching plant. This is producing 10 tons of cathode copper per day.——In the suit of the Elm Orlu company *v.* the Butte & Superior, the former claiming $50,000 damages, the latter has started a counter claim for $100,000 of ore taken from the disputed ground by the Clark property. The Butte & Superior also asks for a permanent injunction and decree of ownership of the ore deposits in dispute.

NEVADA

Churchill County

The August output of the Nevada Hills Mining Co. was 5470 tons averaging $7.08 per ton, yielding a net profit of $3497. Development in the mine totaled 531 ft. The financial statement shows resources of $241,827, including silver worth $9396, and concentrate worth $9189. The silver has since been sold at 52⅝c. per ounce.

Clark County

(Special Correspondence.)—As mentioned in the *Press* of September 26, samples of platinum ore sent from here to the U. S. Geological Survey, and forwarded by them to Ledoux & Co. in New York, are reported to have been found to contain platinum to the amount of one ounce and more per ton, in addition to copper and gold. The platinum is in the form of native metal and the occurrence is in limestone connected with dikes from a quartz monzonite intrusion. The Survey will send a field man to investigate the occurrence.

Good Springs, October 1.

According to O. J. Fisk, manager of the Boss mine, a mill run on this ore returned gold 1.84 oz., and platinum, 1.06 oz. per ton. The recovery was 84.08%. Picked samples gave 100 to 575 oz. gold, 125 to 230 oz. platinum, and 30 oz. palladium.

Esmeralda County

The Goldfield Consolidated company's estimated production for September is as follows: Ore mined, 27,846 tons; gross extraction, $302,000; operating expenses, $180,000; and net realization, $122,000.——Net earnings of the Florence mine in August were approximately $15,000.——A rise from 1017 ft. in the Jumbo Extension has opened ore 125 ft. beyond the drifts on the 921-ft. level. Assays vary from $45.26 to $535.80 per ton in gold. Two cars of ore recently settled for by Western Ore Purchasing Co. assayed as follows: gold, 3.45 and 4.14 oz.; silver, 8.35 and 10.10 oz.; and copper 4.10 and 4.50%, worth $83.34 and $98.95 per ton respectively.

Humboldt County

There are only four men left at the new gold district of Haystack.——Quicksilver properties around Imlay and Humboldt are mining as much ore as possible while the price of the metal is high.——At the Antelope Springs mine the adit is in 1300 ft. At 844 ft. a vein was cut, and driven on for 300 ft., showing 4 to 20 ft. of zinc-silver-lead ore. A shipment is to be made soon.——During September the Nevada Packard mine at Rochester produced five carloads of ore, two of which were settled for at $62.41 and $52.22 per ton respectively.

Mineral County

According to John H. Leavell, of Kirk & Leavell, of Salt Lake City, assistant general manager for the Aurora Consolidated, the new mill is treating about 350 tons per day. Remodeling will be finished in a month, and over 500 tons will then be handled. The stamps are crushing 15 tons each per day. About 600,000 tons of $4.81 ore has been exposed above the 300-ft. level. The Company is erecting 30 new 3, 4, 5, and 6-room houses for its employees. There are 175 men working.

(Special Correspondence.)—The Fermina Copper Queen, on

which C. B. James and associates had an option, has been taken up, and men will start work at once in further opening up the many prospects on the St. Patrick and Irma group. This property consists of 44 claims and lies north of Luning, adjoining the Giroux property on the north and the Luning-Idaho property on the south. The surface showing is very promising, one of the best in the district, and its development to date has exposed a large tonnage of 3 to 8% copper ore, with fair silver content. This has been a large producer.——The Wagner Azurite company is placing two Wilfley tables in the leaching plant recently built here, which, with the new filter being installed, will assure a steady run on a large tonnage of ore that has been opened during the past few months.

The Shipper company and Alameda Mines people are getting ready to begin operations at once. Mr. Quinlan is now in Spokane making final arrangements to start breaking ground for a leaching plant for the Alameda company, at which plant will also be treated ore from the Shipper property.——Reports are current that the Luning Gold Mines Co.'s property has been leased to Sacramento mining men, and that active operations will begin early next month.

Luning, September 25.

Nye County

Seven mines at Tonopah produced 11,460 tons of ore worth $232,240 during the week ended October 3.——For the quarter ended August 31, the Belmont company has published the following data: revenue from ore and bullion, $714,611; mining, milling, and general expenses, $379,564; net, $335,047; total net with other income, $347,453; available resources, including $746,953 cash in bank, total $1,387,061. Dividend No. 21 absorbed $375,000. The mine is developing well. The old 175-ton mill at Millers is being remodeled to an all-sliming process using continuous decantation.——The Wandering Boy shaft of the Jim Butler mine is being enlarged and retimbered, and the output of ore will be reduced to 100 tons per day.——The Extension mill is treating 207 tons per day.

The Tonopah Cash Boy Consolidated Mining Co. has issued a statement as to its affairs. Work in the mine was confined mainly to prospecting for the Extension's Merger or Murray vein. The shaft was sunk 460 ft. to 1260 ft. at a cost of $60 per foot. It is in favorable formation. During development water made in the shaft at the rate of 6000 to 7000 gal. per day. This has decreased to 2000 gal. The Victor, on the north, cut a flow of 170,000 gal. per day in its south cross-cut. Cutting an ore-shoot in the Victor is promising for the Cash Boy, and it may be cut by sinking to 1400 ft. Cross-cutting cost $15 per foot. Owing to financial conditions work has been suspended. Receipts from share sales and cash advanced were $31,554; and expenses $31,493, leaving a balance of $61. Liabilities are $3476. There are 76,870 shares in the treasury. There are now 30 men working in the new gold district north of Tonopah, and prospecting is encouraging.

An attempt was made on September 22 to dynamite the office of the *Tonopah Daily Bonanza*. Labor controversies are supposed to be the cause.

OREGON

Malheur County

It is reported that a large deposit of potash of fair quality has been found near the Oregon-Nevada boundary by W. S. Bretz of Winnemucca, Nevada. All the surrounding area has been staked.

TEXAS

According to W. B. Phillips, director of the University of Texas Bureau of Economic Geology and Technology, during the two years ended September 1, 1914, the Bureau has done considerable field and laboratory work, also extensive investigations on the fuels used in the state. Six bulletins have been published, and there is now on hand and nearly ready for the printer a special bulletin to be used as a mineral reference book for Texas. It will contain statistics of mineral production since the earliest times; the mineral resources of each county, with the area, population, property valuation, railroad mileage, etc.; elevations of cities, towns, villages, mountains and mountain ranges; the text of the new mining law; the latitude and longitude of important places; tables of magnetic declination; and other information.

UTAH

Beaver County

In the Leonora claim in the Star district, there is now opened 38 ft. of ore 2 ft. wide, assaying 58.8% lead and 194.8 oz. silver. This property is near the Hoosier, Moscow, and Red Warrior.——A contract has been let to sink a two-compartment shaft 1000 ft. at the Sheep Rock mine. The owners are extracting gold ore from 300 ft.——The Wilbert lead-silver mine resumed work on September 10, with one shift daily underground and in the mill. About 20 tons of concentrate per day is shipped, also some crude ore, some of which assays 54% lead and 10 oz. silver. This is from the 500-ft. level.

Juab County

The 100-ton plant of the Utah Minerals Concentrating Co., being erected below the dump of the Plutus Mining Co., and which is to treat ore from the Chief Consolidated mine dump, may be ready late in November. The mill consists of rolls, tube-mills, and concentrators.——Four blocks of ground are being worked by lessees in the May Day, and some good zinc ore is being shipped. The Company may pay a 3c. dividend this month, equal to $25,000.——At the Lower Mammoth there are 28 men at work, and zinc and lead-silver ores are being mined from 200 to 1800 ft. depth.——A new sub-station for the Utah Power Co. is about finished.

Salt Lake County

Labor claims will be the first to be settled by the receiver of the Ohio Copper Co. No effort will be made to resume work at the mine and mill under the receivership, unless the price of copper rises considerably.——The Tar Baby adit, in the Alta district, is in 1300 ft., and the expected lode formation should be cut within 150 ft. of driving, the present ground being mineralized.

Summit County

Holt-Dern roasting furnaces are to be installed throughout the Mines Operating plant at Park City. A 10-ton test furnace has been under observation during the current year, and a saving of $1 per ton will be made by less volatilization of metals, less dusting, less coal used, and better effect on treatment solutions. The plant will treat 4500 tons of ore per month. The first half of September yielded this Company 8500 oz. silver, also copper-silver precipitate.——A 30-ton Callow test plant has been ordered by the Daly-Judge company to experiment on tailing. The mill is treating from 140 to 150 tons of ore per day, and about 250 men are employed at the property.

WASHINGTON

In *Bulletin* 550 of the U. S. Geological Survey, the ore deposits of northeastern Washington are described by Howland Bancroft; and the Republic mining district by the same author and Waldemar Lindgren. This work consists of 215 pages with illustrations, maps, and index. The area covers the whole of Stevens and Ferry counties, 6000 square miles, and mention is made of the Park City district in Okanogan county. The field work was done in the summers of 1909 and 1910, in 4½ months. The literature on this area is scanty, and this work will be found of value to mining men. The climate at the elevation of 2050 to 2628 ft. is excellent. Mineral discoveries date back to 1865. Transportation arrangements are good.

Ferry County

The San Poil Consolidated Co. has leased to J. L. Harper the San Poil, San Poil Fraction, Baby Fraction, one-half of the Kangaroo and the Snowstorm Fraction, and the East San Poil, Hammond, and Little Joe Fractions, also the San Poil mill. The bond is for four years, calling for a payment of $185,000 on certain terms. The Last Chance mine at Republic has passed into the possession of the Western Union Mines, recently organized by J. L. Harper and West Virginia people. A 1000-ton mill is to be erected soon. Within two months the monthly output of this group of mines will be from $80,000 to $100,000.

Stevens County

Another trial of the oil-burning furnace at the Copper King mine was made on September 30, with satisfactory results. J. J. Anderson is in charge of the plant.

CANADA

Alberta

There are 52 oil companies drilling or about to start in the Calgary district, according to H. T. Irvine, a broker of Spokane. There is confidence in the field, but a lack of money for development. The United well, near the Dingman, is down 2700 ft.; Mowbray-Berkeley, 3000 ft.; Dingman No. 1, 2800 ft.; Dingman No. 2, 1800 ft.; Alberta Petroleum, 2400 ft.; Heron-Elder, 1400 ft.; McDougal-Segur, 3500 ft.; and Monarch, 3500 ft. The latter is in the north field, the others in the south field.

British Columbia

Mining and smelting operations have been suspended at the properties of the British Columbia Copper Co., only a little exploration being done. The management has announced that 10,000,000 tons of ore has been developed at Copper Mountain. The ore averages about 1.85% copper and 72c. gold and silver per ton. Construction work on the new mill has not yet been started, and the size of the mill has not yet been definitely determined. Mining operations in the Rossland district are active and continue to increase. Also mines in the Kootenai and Slocan districts have resumed work. Shipments of ore to the Trail smelter during the third week of September totaled 7261 tons from Rossland mines.

Operations by the Hedley company at its Nickel Plate mine, mill, and power-plant continue at the usual rate. It is expected that the hydro-electric plant will be finished by the end of the year. Water will drive Morgan-Smith twin turbines direct connected to a Canadian Westinghouse 1800-hp. generator. A new 2000-cu. ft. per minute Ingersoll-Rand motor-driven compressor is to be installed at the mine.

KOREA

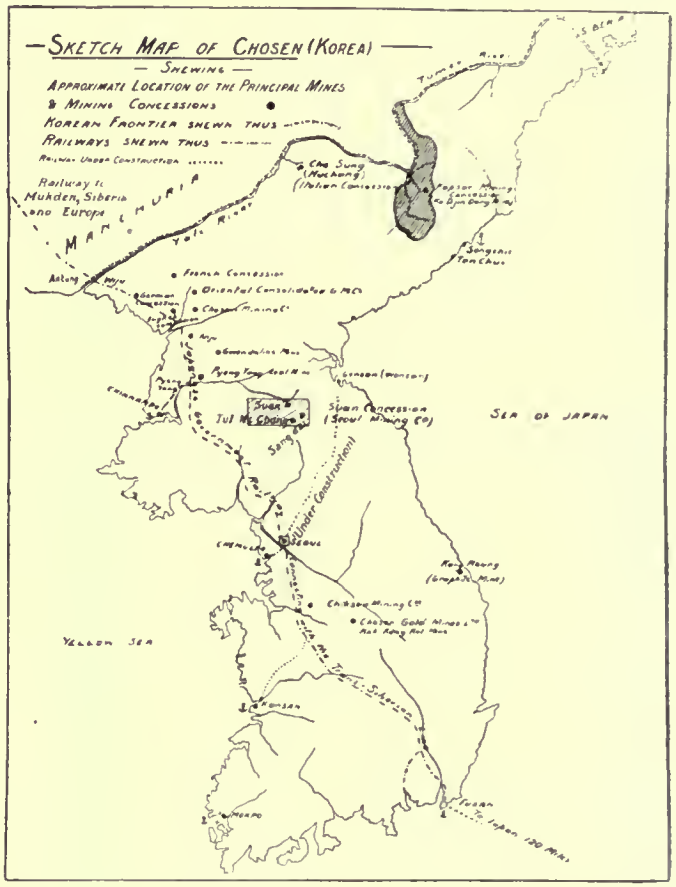
The Seoul Mining Co., operating the Suan Concession in Whang Hai province, reports the following results for September:

Stamps working	40
Time, days	27
Ore crushed, tons	6,005
Total recovery	$61,750
Operating expenses	26,000
Net earnings	35,750

NICARAGUA

Regarding its interests in this republic, the Tonopah Mining Co. of Nevada states that it has an option on the property of the Panama Mining Co. and has until February 1, 1915 to decide whether it will take the property or not.. In case the option is exercised, a new company, controlled by the Tonopah company, will be formed to take title to the property and operate it, and the stock of this new company issued to pay for it. Forty per cent of the stock of the new company will be turned over to the Panama Mining Co. to be disposed of as its officers and stockholders may determine. Under this arrangement, if the option is exercised, the Tonopah Mining Co. buys the property and does not buy the stock of the Panama company. At present it seems that the full period of the option will be consumed before the directors are ready to announce their decision.

In view of the present conditions in Europe, the greatest obstacle to be overcome in the extension of American trade in Nicaragua is that of credits. As coffee is the principal



article of export, and about 90% of it has been going to Europe, the coffee growers and larger merchants do business with European exchange. Accounts in the United States are rarely paid with New York exchange, but usually 30 to 60 or 90-day paper on London or Hamburg, according to a recent *Daily Consular Report* from Washington, D. C. British companies operating in the Corinto district have gold and silver concentrate which will be shipped to San Francisco; the first shipment, on August 16, amounted to about $15,000. Nicaraguan dye-woods will need a market.

Members of the Montana section of the American Institute of Mining Engineers will hold the October meeting on the 16th at the Silver Bow Club, Butte. A technical session will be held immediately after the dinner. The following papers will be read and ample time provided for discussion: 'Coal-dust Fired Reverberatories at Anaconda,' by L. V. Bender, and 'Mining Claims Within the National Forests,' by E. D. Gardner, with discussion by F. A. Silcox, district forester for Montana and northern Idaho.

The Los Angeles branch of the American Institute of Mining Engineers will hold the first section meeting of the season on October 23 at the Hollenbeck hotel. H. W. Morse, of the Western Precipitation Co., will read an important paper on 'Electric Dust Precipitation in Smelter and Cement Mill Practice.'

PERSONAL

HAROLD A. MORRISON is in San Francisco this week.

H. HENDRICKSON has sailed from New York for Vera Cruz.

J. D. IRVING has returned to New Haven from Washington.

E. L. KUATZ has left Columbia University and gone to Pittsburgh.

C. A. CAISPIN, auditor for the Oriental Consolidated Mining Co., is in San Francisco.

HARAV W. NEWTON is now superintendent at the San Poil mill at Republic, Washington.

F. J. LONGWORTH is now on the staff at the Western Union mine at Republic, Washington.

T. WALTER BEAM, of Denver, Colorado, is examining mining properties in British Columbia.

E. J. JONES is now manager of the new zinc smelter at Leadville, in place of A. B. AUGUSTINE, resigned.

ADOLPH KNOPF was in San Francisco returning from a visit along the Mother Lode. He has gone to Nevada.

F. A. CRAMPTON has been retained by the California Magnesite Co. and the Magneso Products Co. as metallurgist.

J. T. TEAAY, Jr., has returned from the Gold Bullion mine, Knik, Alaska, where he erected and operated the first sand-leaching cyanide plant in the territory.

FREDERICK BRADSHAW, of the Tonopah Belmont mine, is inspecting the Company's property at Surf Inlet, British Columbia, with the president, CLYDE A. HELLEA.

CLIFFORD C. ENOS, a member of the Mexican staff of mining engineers for the United States Smelting, Refining & Mining Co., has returned to Mexico after a sojourn in Utah.

H. S. MUNROE has returned to New York rather the worse for his vacation, since hardships undergone in the war zone will prevent his immediately resuming his work at Columbia.

S. H. BRADY has resigned as manager for the West End Consolidated Mining Co at Tonopah and will devote his time to the development of the properties of Thorkildsen & Mather and the Sterling Borax Co. He will make his headquarters at Goldfield, and is succeeded at the West End by J. W. CHANDLEA.

JOHN R. STANTON has been elected president of the Michigan Copper Mining Co. to succeed JOSEPH E. GAY. FRANK McM. STANTON succeeds his brother as treasurer, and GEORGE W. DAUCKER is now the secretary. JAMES DUNSTON is director, succeeding JAMES GAY, and F. M. STANTON follows J. F. HARDLY.

CHARLES F. RAND has resigned as president and director of the Consolidated Coppermines Co. and its subsidiaries in order to devote his entire time to his South American interests. The directors meet October 20 to elect his successor. Mr. Rand is attending the annual meeting of the American Institute of Mining Engineers in Pittsburgh.

Obituary

EDMUND B. PRESTON, who died on Sunday, September 27, at Santa Rosa, California, of pleuro-pneumonia, at the age of 76 years, was born in Calcutta, India, October 17, 1838. He was educated in Germany, his early schooling having been in Dresden. At the age of 22 he graduated at Freiberg with the degree of mining engineer. At Freiberg he was a contemporary with the late Louis Janin and W. S. Keyes. From Freiberg he went to England with the intention of taking up the profession of iron-master, but on the advice of friends decided to come to California, where opportunities were not only more numerous but in many ways more attractive. He reached California in 1860, then a young man of 22, and soon identified himself with gold mining. He was one of the pioneers in the noted Meadow Lake region, in Nevada county, California, where he opened the first assay office in the district, but like several thousands of others when the mines proved disappointing, he walked out of the unfortunate camp over 20 ft. of snow, not even attempting to carry away his assay balances. From Meadow Lake he went to Virginia City, Nevada, where he engaged in engineering work for a time, later returning to Plumas county, California, where he soon found employment as a millman, work at which he was expert. From Plumas county, Preston went to Hayden Hill, in Lassen county, California, and there acquired an interest in some valuable gold mines, which he afterward worked with success for a number of years, finally selling out to advantage. He then came to San Francisco and in 1889 was appointed a field assistant to the state mineralogist, at that time William Irelan, Jr. Preston remained with the State Mining Bureau from that date up to the time of his death, a period of 25 years. He had planned to celebrate the twenty-fifth anniversary of this connection, by giving a dinner on the evening of September 10, to the attaches of the Bureau and some of those who in the past had been connected with that institution, but he was taken ill on September 9 and was unable to carry out his plan. However, he had been able to see fulfilled a most earnest wish —that he be able to complete his 25 years of service.

E. B. Preston had a long and useful career as a mining engineer, geologist, and metallurgist. He contributed valuable material to the Ninth, Tenth, Eleventh, Twelfth, and Thirteenth reports of the state mineralogist, and in his capacity of field assistant he repeatedly visited nearly every county, thus becoming familiar with the mineral resources of the state as he could in no other way, and of this useful knowledge he gave freely to all who sought it. His monograph, 'California Gold Mill Practices,' issued as *Bull.* 6, has had a wide circulation, not less than 10,000 copies having been distributed by the Bureau. It is one of the most valuable contributions to the metallurgy of gold, and has found practical use in the hands of many millmen, with whom it was a veritable *vade mecum*. Other special papers written by him were a description of the flooding of the Salton basin in 1892, and a valuable description of the North Fork mining district at the head of the San Joaquin river. Both of these contributions appeared in the eleventh annual report of the state mineralogist. In 1898 Mr. Preston took the chair as determinative mineralogist which was made vacant by the death of Karl Schneider, who had held the position for years. For 16 years Mr. Preston had occupied this place, having in that time made not less than 35,000 determinations of minerals, rocks, and ores, that are of record in the files of the State Mining Bureau, and many thousands of other determinations for citizens who called to submit their samples in person and of which no record was kept. It is seldom that anyone employed in a state institution continues to serve through one political administration after another for a period of 25 years. When such a thing does occur it is abundant proof of the integrity and capability of this public servant, and of the satisfactory manner in which he performs the duties of his office—such a man was Edmund B. Preston. In the conduct of his department he was not only punctual as to the hour of his arrival, but he was painstaking, careful, and conscientious in all the work he did.

The San Francisco local section of the AMERICAN INSTITUTE OF MINING ENGINEERS will meet Monday evening, October 12, in the rooms of the Engineers' Club, at 8 o'clock. The paper of the evening will be by James M. Hyde. Title, 'History of Flotation Concentration Processes.' The meeting will be preceded by an informal dinner at the same place at 6:30 p.m. Price of dinner, $1.10. Out-of-town members are especially invited to attend.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, October 8.

Antimony	13 —13¾
Electrolytic copper	13⅝—13⅞
Pig lead	3.75— 4.70
Quicksilver (flask)	$55
Tin	36 —37½
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	15

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

New York and London prices for bar silver are 52½c. and 24d. respectively, being a trifle weaker. Exports of silver from San Francisco to Hongkong and China in September totaled $349,125, or about 790,000 oz. Shipments from Cobalt, Ontario, to England, during the week ended September 25 were as follows:

	Bars.	Ounces.	Value.
Nipissing	386	444,537	$234,099
La Rose	48	55,867	29,068
Caribou Cobalt	37	44,803	23,746
Total	471	545,207	$286,913

At the end of September the Constitutionalist authorities at Mexico City detained 512 bars of gold-silver bullion worth about ₱2,000,000, as it was thought that they were to be exported from Vera Cruz by enemies of the new administration. Another 175 bars worth ₱400,000 were held a day or so later. English, German, and Brazilian representatives protested. Export taxes on the bars had been paid. The bullion was claimed by the following: Real del Monte of Pachuca, 175 bars; Cinco Minas, 42 bars; Guanajuato Consolidated Mining & Milling Co., 44 bars; Banco Germanico de la America, 15 bars; Compania Minera La Blanca y Anexas, 364 bars; and El Oro Mining & Railway Co., 23 bars. After an investigation the bullion probably will be returned to its owners.

COPPER

Prices of electrolytic in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	12.34
Mch.	14.72	14.11	Sept.	16.23	....
Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

Electrolytic metal was quoted at 11.70 to 11.80c. on October 2. Exports in September were 19,402 tons, against 19,676 tons in August, and 291,095 tons, against 291,350 tons for the first 9 months of the year. Indications are that there will be a decrease of about 35,000 tons for 1914. If exports are declared only for neutral countries England will not molest cargoes. Stocks in England and France are up 1738 tons, but 1950 tons down in Rotterdam. Anaconda output in September was 12,400,000 lb., compared with 23,800,000 lb. in June; and Mohawk, 1,516,000 lb. 65% mineral, against 1,460,000 in August. Annual loss to shareholders by reduction to date of dividends of copper companies is estimated at $28,639,909.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

June	5.00	4.84	Dec.	5.07	....

The highest price for zinc ore at Joplin, Missouri, last week was $42 per ton basis of 60% metal, while spelter at St. Louis declined to below 5c. per pound. Butte & Superior treated 35,500 tons of 18% zinc ore in September, yielding about 11,000,000 lb. metal.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

The price remains around 31c. per pound. The output of tin concentrate from 30 Nigerian properties in August was 228 tons, while July yielded 435 tons. Royalties and freight rates have been reduced by the British Colonial Office controlling the territory. Shipments from Australia and the Straits were lower in September. About 800 tons is due from London.

Gold exports during the last week of September were $78,000, and $811,566 of silver, a total of $127,598,948, and $32,431,014 respectively for the year. The U. S. Assay Office handled gold worth $4,162,009 in September, against $3,737,756 in August.

COMPANY REPORTS

FIRST NATIONAL COPPER COMPANY

This concern controls an operating company, the Balakiala Consolidated Copper Co., which has a mine and smelter in Shasta county, California. The report covers the year to June 30, 1914. Tests of the Hall process to eliminate sulphur from smelter fume have been suspended for the time. The system was but partly successful, but will be further tested. This plant cost $116,908. After being shut down for three years, the mine was reopened early in 1914, and ore sent to custom smelters, showing a small profit, but owing to the war in Europe the property was again shut down on August 21. All equipment is in good order, and when the price of copper warrants, mining will be resumed. The financial position of both companies is good, the First National having cash $16,322, and accounts receivable, $21,745, with a liability of only $7695; and the Balakiala has cash $260,762, and bills receivable $23,969.

NEW YORK & HONDURAS ROSARIO MINING COMPANY

The thirty-third annual report of this Company, which operates at San Juancito, Honduras, Central America, covers the 15 months ended December 31, 1913, and is just at hand.

Ore reserves in the mine consist of 125,396 tons assaying $16.51, 208,000 tons assaying $8.28, and 21,000 tons assaying $12 per ton, or a total of 355,396 tons averaging about $11.40 per ton. Development totaled 15,689 ft. Sixteen veins, known as the San Miguel, Capitana, Catalina, Buena Ventura, Northwest, Colonia, Nueva, Culebra, North, Socorro, Concepcion, Southwest, San Joaquin, West, Rosario, and Candelaria, are worked. The San Miguel produced 38% and Candelaria 15% of the output. The Southwest vein is developing well, but the country rock is loose, making work dangerous and expensive. The cost of mining was from $5.16 to $4.16 per ton of ore milled. A geological study is being made by V. F. Marsters.

The mill treated 91,606 tons, December being 9700 tons, yielding 1,913,637 oz. silver, and 13,086 oz. gold, valued at $1,379,373. The extraction was 88.24% actual, 90.17% theoretical, and 97.85% by bullion + tailing calculation. The treatment cost was $3.21 per ton. The mill showed mechanical defects during the year, and the Allis-Chalmers company overhauled it by September. The San Juancito and Guadalupe power plants are working at high efficiency, there being plenty of water available. Dwellings, hospital, club house, hotel, and a new laboratory were constructed, and all are comfortable.

The total cost was $9.81 per ton of ore milled. The profit from all sources was $575,343, of which $220,000 was paid as dividends No. 184 to 188. Net cash reserve at the end of 1913 was $291,000. To date, a total of $908,750 has been spent on buildings, plant, etc., and the output since 1882 is $18,741,329, of which $3,310,000 was paid in dividends. Louis F. Valentine is general manager; A. R. Gordon, mine superintendent; and Max F. Soto, local secretary.

BROKEN HILL SOUTH SILVER MINING COMPANY

The report at hand covers the half-year ended June 30, 1914, and the manager, W. E. Wainwright, made in part the following statement: Development in the mine totaled 9500 ft., of which 3979 ft. was diamond-drilling. The 625, 725, 825, 970, 1070, and 1170-ft. levels produced 4, 7.3, 7.8, 26, 36.3, and 17% respectively of the total ore mined during the term. Faces of drifts at 1270 ft. are 438 ft. apart. No. 1 shaft was deepened 178 ft., making a total of 1494 ft. Since then it was sunk to 1509 ft. No. 3 shaft is 1281 ft. deep. Stope filling consisted of 41,836 tons of tailing and ash, at a cost of 91c. per yard of filling, or 22c. per ton of ore mined. Mining cost $3.10 and development 81c. per ton. The mill treated 172,330 tons of ore averaging 15.2% lead, 6.9 oz. silver, and 13.8% zinc, yielding 28,745 tons of concentrate assaying 68.5% lead, 22 oz. silver, and 7.1% zinc, metal contents being 19,679 tons lead, 632,010 oz. silver, and 2034 tons zinc. Zincy tailing amounting to 105,779 tons and containing 16.7% zinc, 3.2% lead, and 3.2 oz. silver, was sold to the Zinc Corporation for flotation treatment. Total recoveries were 88.4% lead, 82.2% silver, and 82.8% zinc. Milling and concentrate cost $1 per ton.

Revenue for the half year was £349,095; profit, £163,480; dividends No. 59 and 60, £140,000; and balance forward, including previous surplus, £143,682. Supplies on hand are £47,750; concentrate, £23,750; fixed deposits at banks, £100,000; and cash, £18,454.

The first unit, of 500-ton capacity, of the slime flotation plant is well under construction, as is the acid and sulphur plants. Old tailing on hand amounts to 900,147 tons, and 378,243 tons of slime. The rainfall was 2.98 in., and water consumption, 34,650,000 gal., 12,282,000 gal. coming from the mine. Owing to the war the mine is only working at half time.

AMERICAN SMELTING & REFINING COMPANY

The report just issued covers the half-year to June 30, 1914. Results are best summarized as follows:

	Half-year, June 30, 1914.	Half-year, June 30, 1913.
Net earnings of all plants and industries.	$5,462,094	$5,200,713
Net earnings from mining properties....	614,727	867,007
Interest, dividends received, etc.....	705,433	603,812
Gross income	$6,782,254	$6,671,532
Administration, taxes, interest, discount, depreciation, etc.	1,815,562	1,643,717
Net income	$4,966,692	$5,027,815
Surplus at beginning of year.....	18,495,943	16,759,402
Gross surplus	$23,462,635	$21,787,217
Dividends on preferred stock:		
American Smelting & Refining Co.....	1,750,000	1,750,000
American Smelters Securities Co., 'A'...	510,000	510,000
American Smelters Securities Co., 'B'...	750,000	750,000
Total on preferred stock.....	$ 3,010,000	$3,010,000
Dividends on common stock:		
American Smelting & Refining Co.....	1,000,000	1,000,000
Total dividends	$ 4,010,000	$4,010,000
Surplus	$19,452,635	$17,777,296

Assets have a total value of $189,659,958, of which ore, bullion, and factory product on hand and in transit is worth net $27,018,480; materials and supplies, $2,943,944; and cash, bills, demand loans, accounts, and notes receivable, etc., $15,922,185. The total is $183,824 more than at the end of 1913. Current cash liabilities amount to $8,459,217; and reserve and suspended creditor accounts, $1,280,607.

Owing to the trouble in Mexico, and difficulties the Company had to contend with in that country, it was thought that dividends would not be earned for the preferred stock, but the president, Daniel Guggenheim, stated that even if no profit should result from Mexican operations, both the preferred and common dividends would be earned, which was more than fulfilled. About $900,000, was spent on additional equipment at the various plants of the Company.

BOOK REVIEWS

MODERN TUNNELING. With special reference to mine and water-supply tunnels. By David W. Brunton and John A. Davis. P. 450. Illustrated, Index. John Wiley & Sons, New York, 1914. For sale by the *Mining and Scientific Press*. Price $3.50.

Much of the material in this volume, though in different form, was recently published as *Bulletin* 57 of the U. S. Bureau of Mines, under the title of 'Safety and Efficiency in Mine Tunneling,' which was reviewed briefly in the 'Recent Publications' of the *Press* at that time. The authors are well known tunnel engineers, and the information in the volume is as valuable as it is up-to-date, containing notes on the recently completed Mount Royal tunnel in Canada, and the Snake Creek tunnel of Park City, Utah, which is about half finished. There are but few books on the subject of tunneling, and these contain mostly historical data. This book covers all such matter in concise form. The various chapters include the history of tunneling, modern mining and water tunnels, power for tunnel work, air-compressors, ventilation, surface equipment, rock-drilling machines, haulage, underground equipment, drilling, blasting, mucking, timbering, safety, costs, a bibliography of 60 pages, and many illustrations explaining the work being done. It is the best volume printed in its field, and the only recent one of note.

IRON ORES. Their occurrence, valuation, and control. By Edwin C. Eckel. P. 430. Illustrated, index. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price $4.

In the production of over 60,000,000 tons of pig iron per annum the world's iron-ore mines are depleted by about 140,000,000 tons, and the large increase in recent years has made necessary the study of all deposits suitable for future production. A great deal has been written on the Lake Superior mines, and the deposits in Sweden have attracted considerable attention. Pig iron now makes up 95% of the total tonnage of all kinds of metal annually produced in the world. In relative natural scarcity of commercial metals aluminum stands first with 7.84% in the earth's crust, iron following with 4.44%, manganese being next with 0.8%. Taking gold as 1, the relative abundance of iron is 8,800,000. The geological and mineralogical occurrences of iron are fully described, also mining conditions, costs, furnace and mill requirements, prices, profits, and markets. The United States produces about 40% of the world's output, and the sources of the ore are fully discussed. The available reserves are estimated as from 5,200,000,000 to 7,550,000,000 tons, while in all America the total is 9,855,000,000; Europe, 12,032,000,000; Asia, 260,000,000; Africa, 125,000,000; and Australia, 136,000,000 tons. The whole subject is intensely interesting and is presented in a novel form.

MODERN PRACTICE IN MINING. VOL. III, METHODS OF WORKING COAL. By R. A. S. Redmayne. P. 210. Ill., index. Longmans, Green & Co., London, 1914. For sale by *Mining and Scientific Press*. Price, $2.

This is one of a series of which the volumes on 'Coal: Its Occurrence, Value, and Methods of Boring,' 'The Sinking of Shafts,' and 'The Ventilation of Mines,' have already been issued. They are devoted to a description in the simplest terms, of coal mining practice, especially in England. The books are designed for students and the special volume under review has the great merit of simplicity, and freedom from an overburden of details. The general features of British coal mining are well brought out, and frequent comparisons are made with continental practice. Just why American practice, with its many interesting features, is entirely ignored is not clear. One feature of the book that deserves comment is Mr. Redmayne's effort to write in English instead of the conflicting jargon of the men in the various British districts. Local terms are used abundantly, but they are quoted, and their equivalents in good English explained. This greatly widens the field of usefulness of the book and is worth noting, since British coal mining engineers, as distinguished from British mining engineers in general, have been persistently insular in this respect. The special chapters in the book cover the subjects of shaft pillars, opening out, main roadways, underground engine rooms and stables, roof support, room and pillar systems, longwall workings, mining pitching beds, accidents, and similar topics. It is an unpretentious but useful book.

METALLURGY. By Henry Wysor. P. 391. Ill. Second Edition. The Chemical Publishing Co., Easton, Pennsylvania, 1914. For sale by the *Mining and Scientific Press*. Price, $3.

That there seems to exist a distinct field for treatises such as this is a serious indictment of the present status of the teaching of metallurgy in this country. This book has the sub-title of 'a condensed treatise for the use of college students and any desiring a general knowledge of the subject,' but it might more correctly be designated as a superficial and inaccurate outline of general metallurgy. Thus, for example, in discussing fuels crude petroleum is not even mentioned, and in considering the factors which govern the choice of a fuel, transportation charges are ignored. In discussing gold the author says "telluride ores * * * are rarely of importance." In treating of the extraction processes for gold, hydraulicking and dredging are classed as amalgamating processes, instead of washing processes, which the author considers as "not of much significance." A dredge is described as "a huge machine for raising, concentrating, and amalgamating soft ores." Electrolytic precipitation of cyanide solutions is discussed at equal length with zinc precipitation, without any hint that the former is not a practical success, while the latter is in universal use. It would be interesting to know where the author secured his material in regard to extraction processes for nickel, for none of those described coincides with the process used by the International Nickel Co., while the Mond process, used by the only other American producer of nickel, is not even mentioned. Under silver all the old material familiar since the first editions of Schnabel is set forth again, while six lines is all the space devoted to cyaniding silver ores, and the methods used at Cobalt are not mentioned. Similar examples can be found on almost every page. If the title page were not dated 1914, one might suppose the book to have been written fifteen years ago. The great pity is that this book is likely to be welcomed in those schools where metallurgy is still taught as a side issue of industrial chemistry.

A POPULAR TREATISE ON THE COLLOIDS IN THE INDUSTRIAL ARTS. By Kurt Arndt, translated from the second German edition, by N. E. Katz. P. 73. The Chemical Publishing Co., Easton, Pennsylvania, 1914. For sale by the *Mining and Scientific Press*. Price, 75 cents.

Several years ago Professor Arndt delivered in Berlin a lecture on the significance of the colloids in the industrial arts. This awakened such enthusiastic interest that he was persuaded to put the lecture in book form so that it might be available to a large audience. In the four years since that time three German editions have appeared, and it has now for the first time been rendered into English, where it is likely to meet an equally hearty reception. Nearly everyone is familiar with the colloids in a general way, and is prepared to admit that they exert a tremendous influence in all phases of industrial activity. But most of the articles and books

dealing with colloids are entirely above the head of the average man, and we have all been waiting for someone like Professor Arndt to tell us in simple language just what is the influence of colloids on industrial processes. How widely he has ranged is shown in the topics covered: Colloidal Solutions, Colloidal Solutions of Metals, Flocculation of Colloidal Solutions, Reversible and Irreversible States of Aggregation, General Remarks on Dispersed Systems, Suspension and Emulsion Colloids, Ruby-Glass, Milky White Opaque Glass, Troostite, Phosphorous, Colloids in the Mineral Kingdom, Silver and Gold Mirrors, Manufacture of Tungsten Lamps, Colloids in the Ceramic Industry, Colloids in the Hydraulic-Cement Industry, Colloids as Adhesives and Glues, Usefulness of the Colloids in the Absorption of Liquids, Dehydration of Peat by Electro-Osmosis, Colloids as Diaphragms and Filters, Adsorption, Varnish-making, Dyeing, Tanning, Soap Manufacture, Brewing Industry, Lubricating Greases, Sewage Purification, and Colloids in Agriculture. No man of scientific training can afford to miss carefully reading this book, and, as a proper preface to it, 'Colloids,' by Emil Hatschek. Without the important ideas which these two little books convey his concepts of chemical technology are as hopelessly out of date as his appearance would be if he went about in clothes and hat of ten years earlier. There are many books in the world, and we can get on very well without reading most of them, but this is one of the exceptions. So valuable a text deserves a better translation; this is painfully literal, and the punctuation theory of the translator seems to be to insert a comma after every sixth word, so that it is frequently much easier to grasp the meaning of the text if the punctuation is disregarded. The translator seems also to be somewhat unfamiliar with mineralogy and general engineering, and the English text at times awakens suspicion as to its fidelity, especially on observing such slips as that on page 55, where 1 cm. has obviously been substituted for 1 c. m. These are defects, however, which can be remedied in the second edition which is likely to be soon called for. The translator deserves gratitude for supplying an index, a convenience which French and German authors have not yet been educated to the point of providing.

RECENT PUBLICATIONS

United States Bureau of Mines publications, Washington, D. C., 1914:

ACCIDENTS FROM FALLS OF ROCK OR ORE. By Edwin Higgins. *Miners' Circular* 17. P. 15, illustrated.

EXPERIMENTS WITH FURNACES FOR A HAND-FIRED RETURN TUBULAR BOILER. By Samuel B. Flagg, George C. Cook, and Forrest E. Woodman. *Technical Paper* 34. P. 31, plan.

FACTORS GOVERNING THE COMBUSTION OF COAL IN BOILER FURNACES. A preliminary report by J. K. Clement, J. C. W. Frazer, and C. E. Augustine. *Technical Paper* 63. P. 46, Ill., Index.

WASTE OF OIL AND GAS IN THE MID-CONTINENT FIELDS. By Raymond S. Blatchley. *Technical Paper* 45. P. 57, Ill, Index.

RESUSCITATION FROM MINE GASES. Report of the committee by W. B. Cannon, George W. Crile, Joseph Erlanger, Yandell Henderson, and S. T. Meltzer. *Technical Paper* 77. P. 36. Illustrated. An interesting summary on a subject being taken up generally in all mining countries.

ELECTRIC LIGHTS. For use about oil and gas wells. By H. H. Clark. *Technical Paper* 79. Petroleum Technology 19. P. 4.

THE ORIGIN OF COAL. By David White and Reinhardt Thiessen. With a chapter on 'The Formation of Peat,' by Charles A. Davis. *Bulletin* 38. P. 390. Index and 54 plates. This is a valuable contribution to a subject which has been often discussed. The authors conclude that all kinds of plants, especially such species as were adapted to the particular region where the deposit was located, in whole or in part went into the deposit. The process of decomposition, elimination, and chemical reduction begun in peat, chiefly by biochemical means, is taken up and continued by dynamochemical means into and through the various successive later stages, and results in the various grades of coal, as lignite, sub-bituminous, cannel coal, and anthracite. Coal, then, is chiefly composed of residue, consisting of the most resistant components of plants.

COAL-MINE FATALITIES IN THE UNITED STATES IN JULY. Compiled by Albert H. Fay. Monthly statement. P. 21. The total was 159 fatalities, compared with 184 in July 1913.

United States Geological Survey publications, Washington, D. C., 1914:

OUR MINERAL RESERVES. How to make America industrially independent. By George Otis Smith. *Bulletin* 599. P. 48. A summary of the mineral deposits of the United States, prospects of new ones, and how to increase the output. Editorial mention has already been made of this publication.

Abstracts from 'Mineral Resources of the United States, 1913':

PRODUCTION OF COBALT, MOLYBDENUM, NICKEL, TIN, TITANIUM, TUNGSTEN, RADIUM, AND VANADIUM. By Frank L. Hess. P. 26.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO. Mines report. By Charles W. Henderson. P. 52.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1912. Part I. North Atlantic Coast Basins. By C. C. Babb, C. C. Covert, and J. G. Mathers. No. 321. P. 240, ill., Index.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1912. Part V. Upper Mississippi River and Hudson Bay Basins. By A. H. Horton, W. G. Hoyt, and H. J. Jackson. No. 325. P. 193, Ill., index.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1912. Part VIII. Western Gulf of Mexico Basins. By W. W. Follett, Robert Follansbee, and G. A. Gray. No. 328. P. 121, ill., Index.

WATER RESOURCES OF HAWAII, 1912. By C. H. Pierce and G. K. Larrison. No. 336. P. 392, Ill., Index.

GEOLOGY OF THE GALLUP BASIN, NEW MEXICO. By Charles T. Kirk. *Bulletin* 76, of the University of New Mexico. P. 68. Ill., plan. Albuquerque, July 1914.

REPORT OF THE SLUDGE ABATEMENT BOARD FOR 1913. P. 21 and 25 plates. Government of Victoria, Australia, Melbourne. 1914. This is an interesting report on dredging in that state, the reduction of débris in rivers, and resoiling dredged ground.

STATISTICS OF RAILWAYS OF UNITED STATES, 1900-1912. *Bulletin* No. 66 of the Bureau of Railway Economics. P. 75. Map. Washington, D. C. This bureau was established by railway companies of the United States for the scientific study of transportation problems, and in this publication is given a mass of details of all the operating roads.

New Machines and Devices

Low Pressure Oil Forge

In sharpening drill steel there are a number of important considerations of prime importance for the best results, and chief among these is the proper heating of the steel. With the coke or coal furnace the fuel invariably contains considerable sulphur, which, if not carefully dealt with, results in the steel becoming sulphurized, causing it to chip and reducing its efficiency. In this type of furnace it is also necessary to work in the blind, the steel being buried in the fuel, which often results in a loss of steel by burning, and it is often found that the steel will not hold its cutting edge for a reasonable length of time.

In the operation of oil forges the chief difficulty has been the inability to obtain a complete and properly regulated combustion which has resulted in volumes of smoke and formation of carbon in the furnace, to say nothing of the noise and other disagreeable conditions under which the operator works. For the purpose of obviating these difficulties, the DENVER FIRE CLAY Co. has developed the Case low-pressure oil forge, which is claimed to embody principles hitherto foreign to forge construction. The oil burner is of special design, permitting of complete control of fuel and its complete combustion. The pressure on the inside of the furnace forces the air from the outside of the mouth of the furnace, thus reducing to the minimum the possibility of oxidation. The lining is of the best fire clay and made in such sections that a new lining may be placed in position or old parts replaced in a very few minutes without disturbing the entire forge. The oil for the burner may flow by gravity or pressure without danger of fire in case the air ceases to reach the burner.

The fan for atomizing the oil is direct connected with an electric motor and the air is used at a pressure of about 6 oz. From ¼ to ½ hp. is necessary for driving the fan. A perforated cross-pipe seen at the front of the furnace and connected with the air main from the fan, acts as a cooling device and affords comfort to the operator.

Little Wonder Battery Stem Guides

The battery stem guide developed and used at the Yellow Aster mine is now being marketed by James A. Little and the Allis-Chalmers Mfg. Co. The guide consists of four parts; the frame, which is made of cast steel, the bushings, which are made of cast iron or cast steel, the gibs, and the keys. The frame is held to the guide girt by eight bolts, and these bolts are the only bolts used. The bushings are the only parts subject to wear and can be replaced at a small cost. They are furnished in halves, if desired, but the one-piece bushings are recommended. The bushing is slipped over the stem; the stem is put into the opening in the guide frame and the bushing dropped into place. The shoulder on the bushing prevents the bushing from falling through the socket. The gib is tightened against the bushing by driving the key to place with a light hammer and the stem is held in perfect alignment. The distance of the stem from the key protects the stem from being marred by the hammer in loosening or tightening the key. The keyway is wider than the key, allowing the head of the key to be inclined toward the operator in tightening the key, or the head can be knocked away from the operator, thus bringing the bottom of the key outward, in which position it is easily loosened by a light hammer. These guides have been in use at the 100-stamp mill of the Yellow Aster Mining & Milling Co., Randsburg, Cal., for more than a year and it is estimated that in that time there has not been a loss of five minutes due to guide troubles.

Perforadoras y Compresoras Sullivan

LA SULLIVAN MACHINERY CIA. de 122 South Michigan avenue, Chicago, Illinois, E. U. de A. ha por distribucion catalogo No. 110 en que es encorporado descripciones cortas de los productos de la Compañia para minas y canteras, compresoras de aire, perforadoras y otros clases de maquinaria. Esta Compañía es una de las mas viejas en Los Estados Unidos y por mas que quarenta años ha fabricada maquinaria de la primera clase para minas y fundiciones. Entre la maquinaria se encontrarón descripciones de compresoras de aire, maquinaria para las minas de carbón, abanicos ventiladores y volquetes de paso automático, perforadoras, barrenas de martillo, malacates, acanaladoras, y otras cosas. Esto librito es muy bien hecho con el objeto dar á conocer á los lectores la Sullivan Machinery Cia., sus productos, su historia, lo que representa y la razón para que se hagan clientes.

Commercial Paragraphs

The WM. POWELL Co. has issued a special booklet descriptive of Powell steam whistles and whistle valves.

The SPRAGUE ELECTRIC WORKS is distributing three new publications: 'Electric Hoists for the Efficient Handling of all Loads'; 'Sprague Electric Monorail Cranes'; 'Sprague Electric Dynometers.'

The Bryant silent call signal system for hospitals, is described in an attractive booklet now being distributed by the BRYANT ELECTRIC Co. Mine managers equipping hospitals will find it of interest.

Lawson loop-line tramways are described in a pamphlet put out by the makers, the CONSOLIDATED TRAMWAY Co. These tramways use the over-hung bucket and find a special field in short-haul transportation.

The INGERSOLL RAND Co. has published Form 8013, dealing with 'Little David' chipping hammers, and Form 8207, describing the 'Little David' drill, the pneumatic tools that are proving popular and finding wide use.

The HARDINGE CONICAL MILL Co. reports that the war in Europe is not seriously interfering with its business in the belligerent countries. Early in September machines were shipped into France and September 24 two 6-ft. ball-mills were sent to Russia by way of Scotland and Archangel.

A COMPLETE report upon the meeting of the American Institute of Mining Engineers held at Pittsburgh last week is presented on page 588. The meeting was well managed, well attended, and of much technical interest.

IN SPITE of the recent troubles in Mexico, necessitating shutting down its smelters there, the American Smelting & Refining Company made more than enough profit during the first half of the current year to pay dividends on all of its stock. Many holders feared that this would not be possible.

CAMBRIDGE UNIVERSITY, England, has offered facilities to the Louvain University of Belgium to move temporarily what remains of that institution to Cambridge. Besides this offer, this seat of learning has provided about 1500 trained men as officers for the regular English army, while the eastern general hospital has been arranged in the courts and grounds of one of the large colleges.

MEMBERS and delegates attending the meeting of the American Mining Congress at Phoenix, Arizona, in December can be sure not only of an interesting meeting but a pleasant visit. The reception committee under the chairmanship of Mr. Will L. Clark, includes Messrs. Walter Douglas, B. Britton Gottsberger, L. S. Cates, C. E. Mills, Norman Carmichael, John C. Greenway, D. C. Jackling, and L. D. Ricketts. We understand that the committee has taken hold in earnest and that no effort will be spared to see that visiting technical men get a correct impression of Arizona hospitality.

ADOPTION of gasoline locomotives for use underground has been retarded because of danger to ventilation, but there have been few observations upon which to determine the exact amount of danger and the range within which the locomotives might be used without special safeguards. The figures therefore presented at the Pittsburgh meeting of the Institute of Mining Engineers by Mr. O. P. Hood, the chief mechanical engineer of the United States Bureau of Mines, are especially welcome. Evidently the situation is one where care in planning and in operation will permit the safe introduction of a form of engine which on surface roads is revolutionizing transportation. The auto-type of locomotive has many advantages underground.

CANADIAN authorities have appointed a special committee consisting of Messrs. O. E. LeRoy, G. C. MacKenzie, E. Lindeman, and J. McLeish, to investigate the need for a government bounty to stimulate iron mining in the Dominion.

THE Engineering Congress at San Francisco will be held in September 1915 as planned. The participating societies, after careful study of the situation and the probable effect of the war, have voted unanimously to carry out the original program. Promises of support are coming from all quarters, and even officers engaged in actual warfare are finding time to write that they will complete their papers at the earliest possible moment and send them in. It is even probable that the volume on military engineering, which had proved the most difficult to provide, will need to be enlarged to accommodate the material offered.

FLOTATION is finding many and wide applications. Mr. Clifford J. Dennis has been conducting experiments at the St. Johns mine on quicksilver ores, and with most gratifying success. With an old ice-cream freezer for apparatus he produced a heavy froth and a clean separation that promises well for commercial results with standard apparatus. This is all the more important since wet concentration of quicksilver ores, while often tried, has never been successful in any large way. The quicksilver mines are all working on lean ore and if flotation can be used, not only may costs be reduced, but the usual result of rendering available much material that is now waste will follow.

OUR recent editorial on tin smelting has called out the information that the most recent geological studies of the Bolivian tin mines give more ground for belief in the persistence of the deposits in depth than was previously available. While in general the workings are still shallow, veins have been proved to depths of 1500 feet below the apex, taking into account work above as well as below the adits through which deposits are worked. Bolivia would seem to afford the best opportunity for developing an independent supply of tin for the United States. The difficulties inherent in the fact that the mines are not well developed and do not carry much ore in reserve, are serious but not fatal. This is a good time to make the attempt.

FATALITIES in the metal mines of the United States, while more numerous in 1913 than in 1912, were at a lower rate, according to figures collected by Mr. Albert H. Fay for the United States Bureau of Mines. The total number killed in 1913 was 683, as compared with 661 in 1912, but there having been 24,000 more men employed, the ratio was 3.54, as against 3.91. All the great mining states of the West, except Colorado, showed a gratifying decrease in the accident rate.

FLOTATION AND THE PATENT LAW

The October meeting of the San Francisco section of the American Institute of Mining Engineers was especially interesting, since laboratory demonstrations and informal discussion displaced set papers. Mr. Edward Steidle, of the United States Bureau of Mines, brought to the meeting plans of self-contained breathing apparatus such as is used in the mine-rescue work of the Bureau and gave a most interesting discussion of the peculiarities, advantages, and disadvantages of each type. Following this, Mr. James M. Hyde told of the development of the flotation process, illustrating his remarks by demonstrations on various ores made with standard laboratory apparatus.

Concentration by flotation has attracted much attention during the present century, both on account of its wide field of application, and the unfortunate amount of litigation in which it has been involved. The process gained great publicity on account of experiments and later the large scale of operation at Broken Hill, New South Wales, where for about 20 years water concentration of the silver-lead-zinc ores gave only 60 to 65 per cent recovery. As the ore contained garnet and rhodonite, which have almost the same specific gravity as zinc-blende, the reason of this low extraction is obvious. Since the adoption of flotation, recoveries on some ores have risen to more than 90 per cent, and the district has produced over 3,000,000 tons of zinc concentrate, equal to 20 per cent of the world's output of spelter during that period. Mr. Hyde briefly named and described the more important patentees and processes, and stated that according to Mr. Theodore J. Hoover, whose work, 'Concentration by Flotation,' is now available in a second edition, 64 individuals are responsible for the present condition of the art. Recent work would add still others to the list.

Flotation was mentioned first by Herodotus, who described how the virgins of that time dipped feathers in a tarry substance, and so caught gold from the streams. In the nineteenth century, Haines, in 1860, patented a process in England. He was followed by Bradford, and Miss Carrie J. Everson in 1886 in the United States. The Everson patent claims are somewhat remarkable, and were the basis of argument in recent flotation suits. Miss Everson's process was tried at Leadville in 1889, and about the same time at a mine in eastern Oregon. Then came Robson in England, and Elmore, who made the first serious attempt to work with the process. Next were Froment, an Italian, in 1902; Potter and Delprat at Broken Hill in 1903; Cattermole; Sulman and Picard; Kirby in British Columbia; the main development of the Elmore vacuum system; Sulman, Picard, and Ballot; De Bavay; Hoover; Horwood; Hyde; Nutter; Lister; Bradford; and Callow. Mr. Hyde explained what led to the adoption of the process at the Butte & Superior mine in Montana. The zinc ore there mined gave only about 60 per cent recovery by water concentration, and slime made in crushing refused to yield its minerals. By treating this by flotation, the recovery was raised to from 88 to 91 per cent. During the second quarter of the current year the mill treated 95,500 tons of ore, assaying 18.28 per cent zinc and 9.85 ounces of silver per ton. This yielded 57,824,296 pounds of concentrate assaying 53.24 per cent zinc. The total milling cost was $2.02 per ton of ore, of which Mr. Hyde estimated the flotation cost as between 50 and 60 cents per ton. At the Broken Hill South mill, crushing and water concentration costs $1 per ton, and the various flotation systems in use on the 'Barrier' average about 85 cents per ton.

As one who has had considerable experience in patents and litigation, Mr. Hyde made pertinent remarks on the patent laws of the United States, and suggestions for the reorganization of the patent office. A patent suit at present rambles from one court to another, and eventually may find its way to the Supreme Court. The ordinary courts should not, he thinks, be allowed to hear any such disputes, especially as the judges are not capable of understanding the technicalities of inventions and disputes arising over them. Procedure in the courts is now far too long, trivialities receiving too much attention. If a patentee is unsuccessful in a suit, he starts another in some other district and attempts to secure a local decision contrary to the first. This should not be allowed. There should be one court, preferably in Washington, for patent business only. It should be presided over by technical men. Another great waste of time and money is the practice of transcribing original testimony in question and answer form into a discourse, for another hearing. Mr. Hyde suggested that the Patent Office be re-housed and given a good library; that proper laboratories be available in which inventors should be required to demonstrate that they have really an invention; minute variations should be cast out; salaries of Patent Office officials should be made worth while; publication of all applications for patent should be required; and much discretion should be left with the patent examiner, as is done in this department in Germany. Mr. Hyde is of the opinion that the whole system of patents in the United States requires investigation and overhauling.

In this general conclusion he is evidently in accord with virtually all who have come into contact with the patent law. No one doubts the value of a patent system, but the present cumbersome and expensive method of determining the validity of a patent places a heavy tax on industry and certainly does not operate to reward inventors.

WORKMEN'S COMPENSATION AGAIN

A general workmen's compensation law went into effect in California the first of the current year. It is still too early to measure the general result, but within a few weeks it became apparent that the cost of indemnity insurance for mining companies had risen to prohibitive figures. We have discussed the various steps that have been taken to meet the situation, and in March we addressed a circular letter to 500 representative mining companies operating in the state, asking for cost data. With the resulting figures in hand, we have conferred with the Industrial Accident Commission and others directly concerned. While all the conferences were marked by the most friendly spirit, there seemed, for the moment, to be little that could be done. Two moves have, however, been made in part as a result of this activity. The Mine Owners' Casualty Indemnity Exchange has been organized and a start has been made toward the formation of a California Mine Owners Association. The present law provides no adequate means of organizing a mutual insurance company and, for reasons that we have already discussed at length, the insurance department of the Industrial Accident Commission has, so far as the mines are concerned, been unable to provide the state insurance that was expected to relieve the situation. The insurance exchange is one means of meeting the situation; a means that has proved adequate and acceptable in various other industries. The one organized for the miners is controlled by two experienced insurance men working with the mining men who have become members, and is enlisting support. There are objections to the exchange plan, but they are not insuperable, and if enough of the mining companies will join the exchange there is no good reason why they should not have excellent insurance at little more than cost. In the meantime the difficulties incident to insurance have brought into the field of action a number of the larger operators who feel that there is need for a general and permanent organization to represent the operating companies. At a meeting held at the Engineers' Club, September 21, an organization committee was formed which is to report to a second meeting held at the same place at 2:30 p.m., Wednesday, October 28. The committee, consisting of Messrs. Henry Mallock, W. F. Kett, William Hague, Gordon Hall, Seeley W. Mudd, and E. A. Stent, is busy drafting a set of by-laws and perfecting plans for the organization. A general invitation is extended to the companies to send representatives to this meeting.

The Industrial Accident Commission itself has not been idle. Despite the large amount of business naturally incident to its first year of work, the members have been carefully studying the situation. Mr. H. M. Wolffin, of the United States Bureau of Mines, has been in the field most of the year as agent for the Commission, and both by correspondence and personal conference the commissioners have been gathering data as to the experience of other states in insuring against the mining risk. The members of the Commission are anxious to afford any possible relief to the mining companies, and with that in view have issued a general invitation to all those interested to attend a conference at the headquarters of the Commission in San Francisco, Thursday, November 5, at 2:30 p.m. It has been suggested that the Commission might be of service in devising and proposing legislation, if any, which would tend to relieve the situation. One of these suggestions takes the form of a proposed state managed or state supervised mutual insurance company designed to secure protection to the companies at cost. The Commission has no desire to undertake such a charge unless there be a real need for it, but is willing to do what it can to help in any such movement. It is most important that the mining men and the Commission get together. Knowing both, we are satisfied as to the fairness of each, and we believe that the proposed conference will result in real benefit. We strongly urge mining men to arrange to attend.

PIONEERING IN OLD COUNTRIES

Influence of frontier conditions on the life and character of the pioneer of civilization is the subject of one of the many able essays written by Nathaniel S. Shaler. During the past century, frontiers throughout the world have steadily moved closer together until they have in most instances coalesced and disappeared. But within the settled regions there remain many scattered areas, such as the geologist would designate as inliers, in which frontier conditions still obtain. These, however, differ in essential particulars from the true frontier. A frontier is *per esse* remote: these regions are often contiguous to populous cities, and only resemble the true frontier in that they support with difficulty a sparse population. Many of the dangers and difficulties of true frontier life are thus removed, but others remain. The essential function of the pioneer consists in so modifying the aspect of the land that its produce, from being of little value to man, is altered into that which is of much value to man. Frontier problems persist, therefore, wherever arid, sandy, boggy, or otherwise unprofitable tracts of land remain to tempt the stout-hearted man to undertake to remake them nearer to his heart's desire. Even in such old countries as England and Germany large areas of this character still exist. Indeed, ordinary agriculture partakes to a large degree of this frontier problem, for the constant endeavor of the progressive farmer must be to cause crops to grow in increasingly greater abundance on the land which he cultivates. Every farmer is, therefore, to some degree a frontiersman and a geological engineer, for the fundamental problems involve engineering and geological chemistry. So although the frontier may go, many of its attributes will long remain with us, and its usefulness in character building will thus extend beyond the generation which sought the bounds of civilization, there to hew out a home.

Pittsburgh Meeting of the A. I. M. E.

EDITORIAL CORRESPONDENCE

PROGRAM

THURSDAY MORNING, OCTOBER 8

Register at General Headquarters, Schenley hotel, in charge of the secretary, Bradley Stoughton. Distribution of programs, badges, and committee ribbons, booklets to members.

THURSDAY AFTERNOON, OCTOBER 8

2:30 P.M.—Carnegie Library and Institute. Lecture Hall, rear of Museum. Address of Welcome by W. J. Holland. General technical session.

THURSDAY EVENING, OCTOBER 8

8 P.M.—Carnegie Library and Institute. Lecture Hall, rear of Museum. Informal reception, followed by illustrated lecture at Carnegie Lecture Hall on 'Ancient Methods of Manufacture of Iron in China,' by T. T. Read. Illustrated moving-picture lecture on 'Safety Methods in Mining' by representatives of U. S. Bureau of Mines: three reels showing method of mining anthracite coal at Nanticoke, Pennsylvania, explained by J. W. Paul. Two reels showing mining of iron ore at Mineville, New York, explained by Edward Higgins.

8:25 P.M.—Special excursion to Allegheny Observatory for the ladies and members by special trolley car, leaving Hotel Schenley at 8:25 P.M. and the Observatory at 10:25 P.M.

FRIDAY MORNING, OCTOBER 9

9:30 A.M.—Technical sessions of: Iron and Steel Section, Lecture hall School of Applied Industries, Carnegie Institute of Technology. Coal and Coke Section, State Hall, University of Pittsburgh. Non-Metallic Mineral Section, Hotel Schenley.

10:25 A.M.—Excursion for the visiting ladies and members to Heinz company's works.

FRIDAY AFTERNOON, OCTOBER 9

Excursions:

12:40 P.M.—Experimental mine at Bruceton. Leave Hotel Schenley by special trolley car for B. & O. R. R. station. Train leaves B. & O. R. R. station at 1:30 P.M. Round-trip tickets should be procured at B. & O. R. R. station.

1:25 P.M.—National Tube Co., McKeesport plant. Leave Hotel Schenley by special trolley car.

1:30 P.M.—Carnegie Steel Co., Homestead Steel Works. Leave Hotel Schenley by special trolley car.

1:35 P.M.—Harbison & Walker brick works. Leave Hotel Schenley by special trolley car.

FRIDAY EVENING, OCTOBER 9

7:15 P.M.—Informal subscription dinner at Hotel Schenley, banquet hall. Tickets for the dinner at $3 each should be secured at the registration desk.

SATURDAY MORNING, OCTOBER 10

9:30 A.M.—Technical sessions of: Petroleum and Gas Section, Hotel Schenley. Electricity and Miscellaneous Mining Topics, Hotel Schenley. Iron and Steel Section, Hotel Schenley.

SATURDAY AFTERNOON, OCTOBER 10

Excursions:

12:40 P.M.—Oil and Gas District at Oakdale, Pennsylvania. Leave Hotel Schenley on special trolley car for Pennsylvania station. Train leaves Pennsylvania station at 1:30 P.M. Round-trip tickets to McDonald, Pennsylvania, should be procured at Pennsylvania station.

1:40 P.M.—Bureau of Mines. Leave Hotel Schenley by special trolley car.

The 109th meeting of the American Institute of Mining Engineers was held in Pittsburgh on October 8, 9, and 10, under the auspices of the Iron and Steel, Coal and Coke, and Non-Metallic Minerals technical committees. The headquarters for the meeting was the Hotel Schenley, technical sessions being held in the nearby buildings of the Carnegie Museum, Carnegie Technical Schools, and the University of Pittsburgh. The morning of October 8 was devoted to registration at the Hotel Schenley and foregathering by the members, of whom many had come from a considerable distance. The management of the hotel unfortunately had failed to provide more than a few rooms, so that even some of those who had made reservations in advance failed to secure accommodations. The local members rose to the situation at once, however, and provided their visiting brethren with cards to the nearby Athletic and University clubs.

THURSDAY AFTERNOON

The technical sessions were formally opened in the afternoon by an address of welcome by W. J. Holland, director of the Carnegie Museum, on behalf of the city of Pittsburgh and of the local technical organizations. This was followed by a technical session, over which S. A. Taylor, chairman of the Executive Committee, presided. L. C. Morganroth presented a paper on the occurrence, preparation, and use of magnesite, which was briefly discussed by R. V. Norris, E. G. Spilsbury, and T. T. Read, the discussion turning chiefly on the possibility of the use of California magnesite in place of the Grecian magnesite now used in this country. The chief use of magnesite is for refractories, for which it must be dead-burned, and the views of Mr. Morganroth were that the California magnesite was more difficult to burn, mining costs in California were higher than in Greece, and freight charges from California were too high to permit shipment to the Eastern seaboard in competition with Grecian magnesite. A paper by E. C. Harder on the iron ores of Brazil was read in abstract by the secretary and briefly discussed by I. C. White, who emphasized the present lack of transportation facilities there, but pointed out that the present lack of coal may be overcome, since experiments have shown that the low-grade coal present can be washed and briquetted into a satisfactory fuel. George S. Rice next described the investigations of coal mine explosions being carried on by the Bureau of Mines at its Pittsburgh station, the paper being in some degree preparatory to the excursion to the experimental mine the following day. The technical session was concluded by a paper on the appraisal of coal lands for taxation, by H. M. Chance, read in abstract by R. V. Norris. This elicited vigorous discussion, as this topic always

does, the conclusion, as always, being that any scheme of taxation is unsatisfactory.

Thursday Evening

In the evening an informal session was held, again in the Carnegie Museum. Thomas T. Read briefly described the primitive methods of iron metallurgy and of deep-well drilling practised in China, illustrating how an elaborate technology can be worked out by the use of purely empirical methods. This was followed by a set of three reels of motion pictures, made by the Bureau of Mines, illustrating anthracite coal mining, and intended to impress on miners the need for safety precautions. These were explained by J. W. Paul, of the Bureau of Mines, and a second set of two reels, similarly illustrating iron mining at Mineville, New York, was explained by Edward Higgins. An alternative entertainment had also been provided at the Pittsburgh Observatory, where a new 30-in. refractor has just been constructed, and which several of the members took the opportunity to see.

Friday Morning

On October 9 three technical sessions were held in the morning, beginning at 9:30. The coal and coke session, over which R. V. Norris presided, met in the State hall of the University of Pittsburgh. H. N. Eavenson presented a paper on coal dust explosions, and in discussing this, S. A. Taylor suggested that since certain explosions of dynamite have been traced to wireless telegraph waves, the extension of this means of communication was possibly a new menace to safety in coal mining. A paper by A. E. Gibson on an aerial tramway for mining cliff coal was read by title, and S. A. Taylor pointed out that this was an unusual procedure and that the paper merited a good deal of attention. The paper by M. B. Yung, on the tin and coal deposits of the Fu Chuan district, China, was read by title, and T. T. Read indicated some of the more important features of the paper, George S. Rice also taking part in the discussion. J. P. K. Miller then described the manufacture of coke, illustrating his talk with numerous slides of by-product ovens. I. C. White, in the following discussion, pointed out that the use of by-product ovens was an example of true conservation and that not only the engineering profession, but the country as a whole is to be congratulated on their growing use. W. H. Blauvelt pointed out that by-product coke, at one time regarded as of inferior quality as compared to bee-hive oven coke, has demonstrated its superiority for many uses, one of its good features being its uniform quality. Referring to the dye-stuff industry and others based on coke oven by-products, he pointed out that the present situation is exactly similar to that of the tin-plate industry 25 years ago, and that ample raw material, chemical skill, and the willingness to produce such by-products are here available. If the industry can be protected by a tariff until it is firmly established here it will then be able to maintain itself without a protective tariff, but it is impossible to establish it without such aid. The other papers on the program were read by title and there was no discussion. About fifty members were present.

At the iron and steel section, which met in the Carnegie Technical Schools, and over which Albert Sauveur presided over 80 members were present. The paper by G. K. Burgess and others on the finishing temperatures and properties of rails attracted much attention and elicited general discussion, in which Messrs. Trimble, Webster, Dudley, Waterhouse, Weckhorst, Aston, Kenney, Gibbs, Waldo, Aiken, and Burgess participated. The paper by J. K. Furst, on the duplex process for making steel was read by title, and was discussed at some length, Messrs. McJohnston, Hebbard, Stoughton, McQuaid, and A. J. McKee taking part. Albert Sauveur then briefly summarized his paper on manganese steel and the allotropic theory, and written discussion by H. M. Howe and G. K. Burgess was read, to which Albert Sauveur replied briefly. The other papers on the program were read by title, and there was no discussion.

The section on non-metallic minerals, over which Heinrich Ries presided, met in the Hotel Schenley, and though the attendance was small, it was select. David T. Day presented the paper by W. C. Phalen on the making of salt by solar evaporation. The other papers on the program were by E. H. Sellard on the mining of phosphate, and by J. A. Barr on Tennessee phosphate practice. In the general discussion, J. A. Dresser, O. B. Hopkins, D. T. Farnham, H. A. Gardiner, and G. B. Heckel participated.

Friday Afternoon

The afternoon was devoted to excursions. A large number went to the experimental mine of the Bureau of Mines at Bruceton, Pennsylvania, where the visitors were first shown through the mine, and then an explosion was set off, the crowd being grouped on the hillside to view the effects. Following the explosion, a trained crew was sent into the face to demonstrate rescue methods, after which the gases were blown out of the mine and the visitors were again permitted to enter and view the effects of the explosion. George S. Rice and J. W. Paul, of the Bureau of Mines, had charge of this excursion, which was handled with unusual skill and awakened much interest in the methods and results of the Bureau's work. A second party went to the McKeesport plant of the National Tube Co., a third to the Homestead steel works of the Carnegie Steel Co., and a fourth to the Harbison & Walker refractories plant. All these excursions were well attended.

Friday Evening

In the evening a subscription dinner was held at the Hotel Schenley, 135 members and guests being in attendance. After the dinner, over which S. A. Taylor presided, B. B. Thayer, Bradley Stoughton, and C. F. Rand spoke for the Institute, Mr. Thayer pointing out the growth which the Institute had made during the past year. The secretary of the Engineers' Society of

Western Pennsylvania spoke on behalf of that organization, and Mr. McCormick, chancellor of the University of Pittsburgh, graeefully expressed the welcome which the Pittsburgh members and the local organizations had extended to their visitors. I. C. White told of the importance of Mexico in the oil-production field, and Philip N. Moore dwelt on the rapid growth of the Institute in recent years. The feature of the evening was the reminiseences of Edmund Peehin, one of the four surviving charter members of the Institute. Mr. Peehin, though over 80 years old, is still active of body and mind, and his aeeounts of the first meeting of the Institute in Pittsburgh and of events of the following years were greatly enjoyed by all. E. Gybbon Spilsbury related an amusing story of an iron-eating insect, constructed by himself and brother students in Germany many years ago, and which has been bobbing up in the daily papers of the world ever since.

Saturday Morning

On Saturday the sessions were all held at the Hotel Schenley, and the meeting rooms were crowded to full capacity. The program of the various sessions was as follows:

Petroleum and Gas—C. W. Washburne, 'The Capillary Concentration of Gas and Oil;' L. Edeleanu, 'Refining Petroleum by Liquefied Sulphur Dioxide;' general discussion on 'Gas and Oil Wells through Coal Seams.'

Electricity and Miscellaneous Mining Topics—S. S. Rumsey and W. F. Schwedes, 'A Test of Centrifugal Motor-Driven Mine Pumps;' O. P. Hood, 'Gasoline Locomotives in Relation to the Health of Miners;' G. S. Rice and H. H. Clark, 'Shot-Firing in Coal Mines by Electric Circuit from the Surface;' general discussion on the 'Use of Electricity in Mines' (under the direetion of the committee on the use of electricity in mines).

Iron and Steel—J. C. H. Ferguson, 'Rolled Steel Roll Shells;' J. V. Emmons, 'Surfaee Decarbonization of Tool Steel;' R. H. Rice, 'Turbo Blowers for Blast-Furnace Blowing;' Edwin Higgins, 'The Safety Movement in the Lake Superior Iron Region;' Harrison Souder, 'A New Safety Detonating Fuse.'

The session of the committee on use of electricity in mines was presided over by William Kelley, and concluded with a general diseussion of the advisability of appointing a committee to formulate a set of rules governing the use of eleetricity in mines. It was the consensus of opinion that the distinction between rules intended for the operator and regulations to be enacted into state law should be kept clearly in mind.

The session of the committee on iron and steel was presided over by E. Gybbon Spilsbury. The various papers listed were read and discussed at a length that forbids summation here.

The session of the committee on petroleum and gas had for presiding officer David T. Day. The meeting was largely devoted to discussion of methods of refining oil. It ended with a general discussion of the problem of drilling wells through coal beds.

Saturday Afternoon

In the afternoon most of the members went to Oakdale, Pennsylvania, to visit the oil and gas district there, while a smaller group visited the Bureau of Mines plant in Pittsburgh. At noon the committee on nominations, W. J. Cox, chairman, held its meeting and made its report, which will be published in the November *Bulletin*.

Between 275 and 300 members and guests were registered as in attendance at the meeting, and the enthusiastic interest manifested in the technical sessions was a tribute to the quality of the papers presented, and to the skill and energy displayed by the chairmen and members of the eoal and coke, iron and steel, petroleum and gas, non-metallic minerals, and electricity committees which had general charge of the meeting. No less is credit due to the members of the local committees, who were:

Executive Committee—S. A. Taylor, chairman; G. S. Rice, K. Seaver, J. S. Unger, F. C. Phillips, O. P. Hood, C. F. W. Rys, secretary.

Reception Committee—Dr. W. J. Holland, chairman; Dr. S. B. McCormick, Dr. A. A. Hammerschlag, Dr. John A. Brashear, A. C. Dinkey, Taylor Allderdice, Ralph Harbison, Joseph Guffey, W. K. Fields.

Finance Committee—S. A. Taylor, chairman; K. Seaver, C. F. W. Rys.

Entertainment Committee—W. L. Scaife, chairman; W. G. Wilkins, E. K. Hiles, John W. Boileau, W. E. Fohl, W. W. Keefer.

Committee on Arrangements—H. B. Craver, chairman; Frederick Crabtree, H. B. Mellor.

Costs at the Goldfield Consolidated mine and mill in August were as follows:

Mining:	Per ton.		Per ton.
Stoping	$2.31	General expense	$0.48
Development	0.60	Bullion tax	0.08
	$2.91	Construction	0.41
Shipping expense	0.05	Filter royalty	0.05
Contract ore	0.39		
Dump moving	0.04	Total cost	$6.49
Transportation	0.07	Miscellaneous earnings	0.25
Milling	1.93		
Marketing	0.08	Net cost	$6.24

Bismuth production of the United States in 1913 was estimated to be 157,300 lb., worth $273,650. Imports were 117,747 lb. valued at $213,257. No large deposits have been found in this country. The output in foreign countries in 1912 was as follows: Australia, metal and ore, 257,802 lb., worth $72,530; Bolivia, ore, 1,053,799 lb., worth $83,637; Peru, metal in ore, 112,518 lb., worth $68,885; Saxony, refined metal, 7145 lb., worth $12,763; and Spain, ore, 160,965 lb., valued at $1801.

Gold production of Alaska to the end of 1913 was $228,392,540, of which $15,626,813 was recovered in 1913.

How to Make Money Though Mining

In the course of an address before the northern California and southern Oregon Mining Congress a few weeks ago, William A. Burr gave some excellent advice that we cannot do better than reproduce. He said:

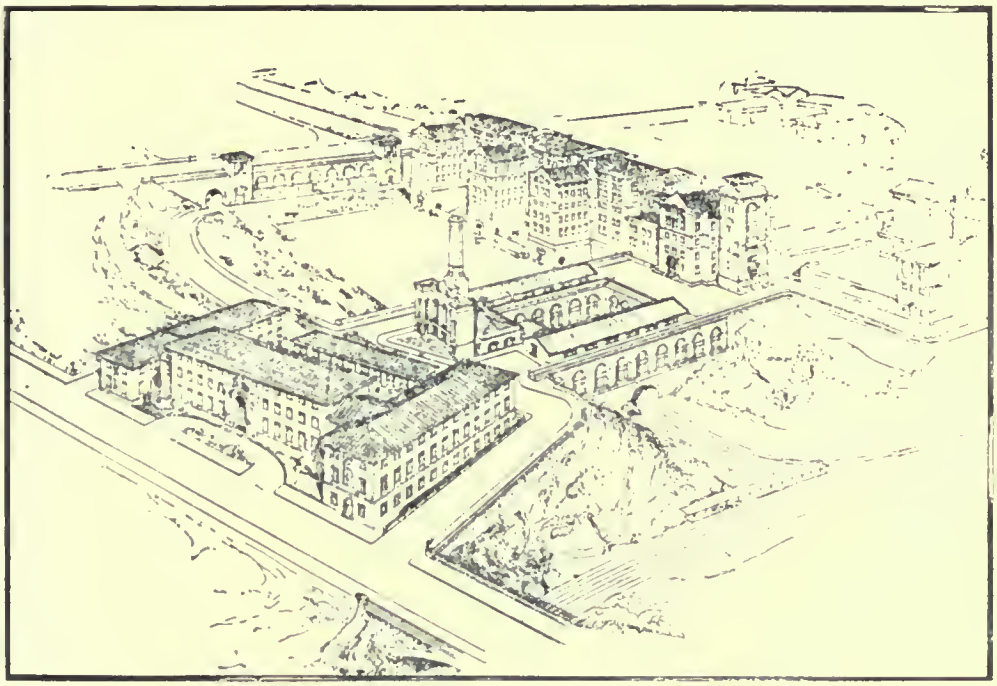
Keep the mill running, keep the stamps dropping; don't hang up for every little thing. Teach your men to change screens in three minutes; to dress plates, if you insist on amalgamation, in ten minutes. Teach them to adjust a tappet on one stamp with the other four dropping. Teach them to feed so that the stamps will rebound without pounding cold iron. Teach them to keep grease on the cam shaft and bearings and not in the mortars and on the plates. Teach them to make repairs without shutting down the mill. Teach them to make the concentrators do their work, and not to try to secure results from them with an inch of pulp running over them. Teach them to keep track of the time lost by various machines and of the reason for such lost time. This gives them a due appreciation of how much the capacity of the mill is being curtailed by the 'hanging-up' habit, affords a basis for the accurate approximation of the tonnage passing through the mill, gives a line on the competency of the mill man in manipulating the plant, and serves as an indicator for the management and the metallurgists as to defects in the machinery or in its installation.

Above all else, teach them to keep the mill clean. The mill man who turns his shift over with shafting and machinery lubricated and floors swept and dry, is entitled to protest if the man on the opposite shift does not turn the mill over to him in the same way. If you are cyaniding, teach him not to try to filter through a one-eighth inch carbonate of lime. Teach him to run the tanks, samples, and solutions by the clock, to plug leaks in tanks and launders and avoid losses in solution, as that means losses in money.

In conclusion I will say, don't decry the scientific part of milling and other branches of metallurgy, but absorb as much of it as you can, subscribe for the leading mining magazines and journals, they will get you abreast and keep you abreast of the times. Hydro-metallurgy is making great strides, it has brought about a new era in many gold and silver camps which were formerly hopelessly unprofitable. It is doing the same thing for copper camps today.

New Buildings of Bureau of Mines

Coincident with the opening of the meeting of the Institute of Mining Engineers at Pittsburgh, detailed plans for the $500,000 group of buildings for the United States Bureau of Mines were made public. The main building, in the front of the group, is divided into three parts, the central being for the mining engineering department and the administration offices, the east wing for the electrical engineering department, and the west wing for mechanical engineering. The architecture conforms with that of the Carnegie Technical Schools buildings. The building in the rear will house the testing laboratories. On each side of it, subsidiary buildings will bridge the hollow between the mines group and the Tech plant. Between the front and rear buildings there will be entrances to several experimental mining shafts. Only $150,000 of the $500,000 authorized by Congress to be spent in the erection of the group has thus far been appropriated, but it is believed that sum will cover the cost of the plans, the preparation of the site and the foundation work.



PROPOSED GROUP OF BUILDINGS FOR THE U. S. BUREAU OF MINES AT PITTSBURGH, WITH BUILDINGS OF THE CARNEGIE TECHNICAL SCHOOL IN THE BACKGROUND.

The war being waged adjacent to their countries has affected Swedish and Norwegian undertakings considerably. The Kurunavaara and Luossavaara iron mines are working, but the ore is being stored; the Kjöli pyrite mines are closed; construction at the Nitrogen Products & Carbide Co. has been suspended; the great Dunderland iron mines have stopped construction; the Foldal Copper Co. has increased its working force; the Evje nickel works near Christiansand is again at work; and the Hafslund carbide plant is to resume; while other corporations, constructing hydro-electric plants, etc., have reduced their staffs, or are paying lower wages.

Gasoline Locomotives and the Health of Miners

By O. P. HOOD

*None of the methods now in use for the transportation of materials underground is entirely free from objections. The great flexibility, ease of control, and economy of operation of electric tramming is accompanied by the serious menace of a trolley wire. As the gasoline locomotive has even greater flexibility of application and requires no similar dangerous distributing system, it might be considered a safety device which would make possible the elimination of the dangerous trolley were it not possessed of other objectionable qualities peculiar to itself. It is found that the exhaust gases from the engine may be injurious to the health of those breathing the air in which the locomotive has been operating. While electric shock may kill the individual who makes contact with uninsulated parts, the gasoline engine may be detrimental to the health of all those who have to work within the atmosphere corrupted by its exhaust gases. The degree of pollution measures the magnitude of the menace. This may be negligible at times, but with careless operation it becomes serious. The exhaust gases from an engine are composed of nitrogen, a little free oxygen, hydrocarbons, hydrogen, carbon monoxide, and carbon dioxide, the last two being considered dangerous.

Effect of Carbon Dioxide

The presence of carbon dioxide as a product of combustion of the gasoline was recognized as an objection from the beginning of the use of these machines, but attention was called to the fact that the amount produced was relatively small as compared to other sources of this gas, and it was not likely to be made in dangerous quantities. The effect of carbon dioxide, except in relatively large percentages, is confined to reducing the oxygen content of the air that is breathed.

The presence of carbon monoxide in the exhaust gases in injurious quantities was less apparent, but it appears from what is now known that this is the limiting factor in the use of these locomotives if they are not to be injurious to health. The presence of carbon monoxide in the air in relatively small quantities has been shown to have a marked effect upon the blood, producing sickness, and, if inhaled in sufficient quantity, death.†

It is difficult to get those most conversant with the effects of carbon monoxide to assign a definite limit to the amount which may be in the air without detriment to health. There is no sharply defined line on one side of which is to be found safety, with danger on the other side. It has been shown that the physiological effects vary with different people, and with the state of health and degree of activity required of the individual, so that a condition which may be considered safe may prove to be unsafe under conditions of harder work and unfavorable physical state. After careful inquiry, the best that can be stated at this time is that, without injury to health, no more than 0.1% of carbon monoxide can be breathed and that for short and infrequent intervals. It is probable that one-half of this percentage could be allowed for a considerable period of time without noticeable effect.

Protection Against Carbon Monoxide

The per cent of carbon monoxide in the mine air depends upon the amount made by the engine and on the quantity of air with which it is mixed. It will be necessary to provide ventilation for the worst possible combination of gases which such engines can make under unskillful handling, or else to become informed as to the actual amount of carbon monoxide produced and provide air accordingly. To provide for the worst conditions it becomes necessary, then, to consider the gasoline locomotive as a carbon monoxide producer, and to discover the maximum quantity of this gas which any engine is capable of making. It is not sufficient to consider the average amount produced as distributed over the whole time of running such a machine. The total quantity of gasoline burned in any one day may have produced but a small quantity of carbon monoxide, but if this has been confined to a relatively short period during bad carburetor adjustment, and in some poorly ventilated space, the momentary percentage may be very high and the consequences may be fatal. It is evident that to be entirely safe the ventilation must be sufficient to keep the percentage of carbon monoxide below the assigned limit when the engine is producing the maximum quantity possible. If this maximum quantity is provided for by proper ventilation, the chance of injury to health may be considered to be remote. Certain peculiarities of gasoline engines cause the percentage of carbon monoxide generated to vary between rather wide limits, but the maximum is fairly constant. No other constituent of the exhaust gases varies so much or so rapidly with slight changes of adjustment as does the carbon monoxide.

Maximum Gas Production

Extended experiments have been made by the Bureau of Mines to determine under what conditions of running such locomotives give a maximum quantity of carbon monoxide. This maximum quantity is found when the engine is running at full load and full speed, and when burning the greatest quantity of gasoline which will

*Prepared for the Pittsburgh meeting of the Amer. Inst. Min. Eng., printed by permission of the director of the U. S. Bureau of Mines.

†A discussion of the effects of these gases is to be found in *Tech. Paper* 62, U. S. Bureau of Mines, by G. A. Burrell, F. M. Seibert, and G. W. Robertson.

maintain these conditions. Any further enriching of the mixture results in weaker explosions, misfires, and reduction in speed of the locomotive, and thus a reduced total quantity of gases. The weight of gasoline used per stroke may vary nearly 100% without varying the speed or power. As the mixture is enriched the combustion is less complete, reducing the efficiency but affecting the power but little until the upper limit of explosibility is approached, when the power falls rapidly. Under these conditions a maximum quantity of carbon monoxide equivalent to 5¾% of the piston displacement may be generated and delivered into the surrounding air. When the engine is throttled down to a slow speed and with a light load it is possible to produce exhaust gases containing a greater percentage of carbon monoxide, but the total quantity is less because of the slow speed of the driving engine. It can therefore be stated that the amount of carbon monoxide possible to generate with a gasoline locomotive is a function of its piston displacement.

The sizes of locomotives in common use at present are given in the accompanying table, together with the maximum quantity of injurious gases which they may generate.

The air with which the exhaust gases are mixed is the air passed by the locomotive. If the speed of the air current and that of the locomotive are the same there would be a concentration of exhaust gases immediately surrounding the engine, which would very soon reach the danger limit. The engine runner would be exposed to this excessive amount. Similarly, the air may be stationary, and if the locomotive passes through this air at such a rate as to distribute the exhaust gases into the required quantity of air the dilution may be below the danger limit. It becomes necessary, therefore, to investigate the relative velocity of the locomotive and the air current, together with the cross-section of this air current in order to determine whether a sufficient quantity of air is passed to insure a proper dilution. The mixing due to the movement of the cars and the diffusion of the gases is expected to distribute the gases through the air.

An investigation of this kind will frequently disclose some portion of the run of the locomotive where the air and the locomotive are traveling together and the dilution is insufficient, forming the basis for just complaint. By a change in the speed of the locomotive, or more careful running, perhaps with lighter loads, these difficulties can frequently be overcome. It is evident from the foregoing that it is a dangerous practice to allow locomotives to stand idle for any length of time in situations where there is not ample movement of air. The introduction of a self-starter on locomotives which are compelled frequently to wait for cars would be a great aid. The engines on these locomotives are usually difficult to start, and to stop the engine whenever the locomotive is compelled to wait for a few minutes would not be practicable unless some easy means of re-starting

TABLE I

Engine cylinder size, inches.	Number of cylinders.	Speed, r.p.m.	Piston displacement (cu. ft. per min.)*	Maximum probable amt. of noxious gases (cu. ft. per min.) at 60 F. and 30-in. barometer produced with				Amt. of air (cu. ft. per min.) required to dilute exhaust gases to 1 part carbon monoxide per 1000 parts air.†

*Area piston in square feet by stroke in feet by number of cylinders by revolutions per minute.
†Amount of carbon monoxide allowed for short and infrequent intervals and which must not be exceeded.

The size of a locomotive that may with safety be introduced into a mine depends upon the amount of air that can be mixed with the exhaust gases in the most unfavorable portion of the run of the locomotive. For each cubic foot of carbon monoxide possible to generate in the engine there should be available 2000 cu. ft. of air to mix with the exhaust gases if this air is for continued breathing, while for short and infrequent intervals the proportion may rise to one part in one thousand.

was provided, but this practice would greatly reduce the chance of air pollution.

The requirement that not less than 1000 cu. ft. of air shall pass the locomotive for each cubic foot of carbon monoxide possible for the engine to generate, will limit the size of the locomotive in many cases to sizes less than are now in use. It may also limit the movement of these engines to main entry-ways.

This maximum quantity of noxious gases which is here provided for should not actually be realized with improved carburetor construction and skillful manipulation. The percentage of carbon monoxide in the exhaust gases under the worst conditions is about 13½%, while under normal running conditions the amount seldom exceeds 6%. It is this great variation in the possible amount of carbon monoxide due to unskillful operation that makes the experience of different users of these machines vary through the wide limits noted. If a locomotive is used in a place where the quantity of air is not sufficient properly to dilute the maximum quantity of carbon monoxide, analyses of the exhaust gases should be made to determine just what percentage is actually produced with the carburetor in use and the methods employed in running these machines. The ventilating current may then be regulated to conform to the actual amount of carbon monoxide as found. It is proposed that this be done by a method somewhat as follows:

Suppose, upon analysis, that the actual amount of carbon monoxide is found to be not over 4%; allowing a factor of safety of 2, and assuming that this percentage might on occasion mount to 6%, and, since the maximum percentage possible is about 13½%, the ventilating current required can be regulated in the proportion of 8 to 13½.

If a careful study is made of the amount of air available for dilution throughout the run of a locomotive, and the quantities are kept within the limits that are here proposed, a wide field of usefulness for these locomotives remains, where it is believed there would be no injurious effects upon health.

Thermit Weld of Broken Crank-Shaft

*On February 8, 1914, the engine driving the crushing plant of the Queen of the Hills gold mine, Meekatharra, fractured the crank-shaft. This is a tandem cylinder, 220-hp. gas-engine of English manufacture, and was installed at the mine about six months prior to the above date. The shaft is 13 ft. long and 11 in. diameter, with a single crank of 12-in. throw, the crank-pin also being 11 in. diameter. The cheeks of the crank were 7 by 12 in. rectangular section. The fracture occurred in the cheek of the crank between the crank-pin and the main shaft, partly tearing into the journal of the main shaft. Because of this the mine was idle, as no spare shaft was obtainable in the country. It was then decided to attempt a thermit weld as a temporary expedient to cover the period during which a new shaft could be imported from England.

On February 10 an engineer left Perth for Meekatharra, arriving there two days later. The shaft was inspected, the necessary material ordered by wire from Perth and landed in Day Dawn on the 14th. The shaft was removed from Meekatharra to Day Dawn, where the Company's workshops are situated, about 80 miles distant by railway, reaching there on February 17. By this time the special appliances required for the operation had been manufactured or improvised from material available at Day Dawn. These special appliances consisted of a thermit crucible capable of holding 560 lb. of thermit during its reaction. It was of conical shape, 4 ft. high, with a diameter of 22 in. at the top. The crucible was lined with magnesium cement and dried in a foundry coke-oven.

In lieu of face-plates and 'V' blocks for leveling the shaft, a pipe molding box was secured in the foundry floor, perfectly leveled and capable of taking the long end of the shaft, the short end of the shaft being brought up to the same level on a piece of old boiler plate well bedded in the sand. The fracture in the crank-cheek was drilled and cut out, leaving a gap of 1⅛ in. for the thermit. The crank was set in its proper position relative to the shaft and securely bolted together, a stiff distance piece being inserted between the crank-cheeks to secure alignment. The short end of the shaft was placed $\frac{3}{16}$ in. out of line to allow for shrinkage, and being free on the boiler plate it had nothing to prevent the action. The judgment in deciding to allow $\frac{3}{16}$-in. shrinkage proved to be sound, as on completion of the work the shaft was put in the lathe and found to be perfectly true in every respect. The crucible of thermit was placed in position and all was ready for the reaction on February 20. The crucible contained 560 lb. thermit, and, in addition, 40 lb. of small bright wire nails, 5 lb. of nickel thermit, and 5 lb. of manganese free of carbon. The ignition was perfect, and the crucible securely held during its reaction. As soon as this subsided the crucible was tapped, and the metal successfully run into the mold prepared across the fracture. This mold was run from the bottom and all metal passed up through direct to the gap cut in the crank-cheek, the slag in turn passing through from the runner to the riser. As soon as the crucible was emptied a further charge of 22 lb. of thermit was put into the riser, which had sufficient temperature to ignite it, and so fed the casting through the riser and insured that no gas could be imprisoned.

The whole was left in position as cast till February 21. The spare material round the cast was then removed in the lathe, or by pneumatic chisel. The shaft was returned to Meekatharra on February 25, and the engine again started work on March 1, or only 22 days after the accident. Two tons of plant was required, in order to complete the work, which had to be conveyed by rail a distance of nearly 600 miles.

*Abstract from *Monthly Journal* of the Chamber of Mines of Western Australia.

Mining Methods on the Marquette Range

By Committee of the Lake Superior Institute of Mining Engineers Consisting of H. T. HULST, G. R. JACKSON, and W. A. SIEBENTHAL.

Shrinkage-Stope System

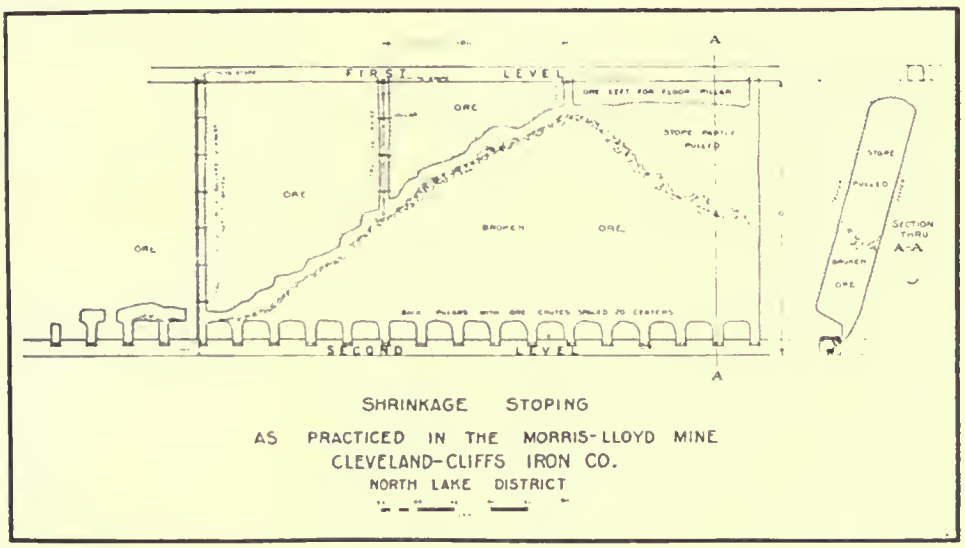
At the Lloyd mine of the Cleveland-Cliffs Iron Co., a form of the shrinkage-stope system has been followed in mining a part of the orebody. A silicious orebody 500 ft. in length, and from 25 to 75 ft. in width, and from 50 to 175 ft. in thickness, has been taken out according to this system. Because it forms the hanging of a narrow high-grade orebody, it had to be mined first. Furthermore, if it was to yield a profit, it had to be mined cheaply. After a study of conditions, the shrinkage-stope system was selected.

The formation in the North Lake district stands at a steep angle, the dip varying from 70 to 85°. In using this system of mining, there was no danger from falls of ground from the back, but special attention had to be given the hanging side of the stope.

The shaft is in the foot-wall 300 ft. away from the ore, this site having been chosen on account of the situation of the loading tracks. Levels were opened 150 ft. apart and crosscuts were driven from the shaft to the ore. Drifts were driven in the ore both ways in the formation to the limit of the orebody. These drifts were timbered with sets four feet apart, 8-ft. legs and 7-ft. caps being used. The orebody was developed by crosscuts turned off every 100 ft. to determine the width and grade. The main haulage drift was driven near the foot-wall, in the wide part of the deposit; a parallel drift was later driven near the hanging, as the orebody was too wide to be removed in one stope. Up to widths of 40 ft. the ore was removed in one stope; greater widths were taken out either in a parallel stope with a pillar between, or by stopes at right angles with pillars between. This latter method was used where pockets of ore extended into the hanging at points above the main level.

As the body was being developed on the main levels, rises without cribbing were put up to the top of the ore every 100 ft. Above the first level these rises connected with each other at the top, and two rises were extended through to surface. The rises from the second level were carried up to the first level and holed on the side of the haulage drift. These rises provided traveling roads to the stopes, ventilation, and a means of bringing in the air lines. Small rises without cribbing, with 15-ft. pillars between, were put up 10 ft. above the level in the main haulage drift. These rises were strongly built, being reinforced with 40-lb. rails and 3-in. hardwood planks, because of the blasting of hang-ups. Chutes were built to these rises. At a point about 15 ft. above the level the rises were connected; the stope was then opened to full size, and mining started. One gang of miners worked about 50 ft. of the stope, or the territory above three rises. Each miner had a drill, there thus being two machines to one contract.

About 30% of the broken ore had to be drawn from the stope to make room for the men to work. One laborer was required to each 100 ft. of stope to sledge the large pieces. Occasionally it was necessary to block-hole large slabs which had been blasted or barred down from the hanging side of the stope. On the completion of the stope, the chutes were drawn as nearly equal as possible, as this seemed to prevent blocking. This system of mining has worked out very satisfactorily as regards costs and safety.

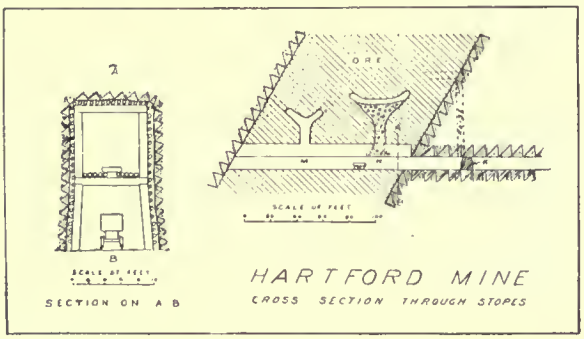


SHRINKAGE STOPING
AS PRACTICED IN THE MORRIS-LLOYD MINE
CLEVELAND-CLIFFS IRON CO.
NORTH LAKE DISTRICT

Stoping System, Hartford Mine—Republic Iron & Steel Company

A comparison of the methods of mining at the Hartford and Section 21 mines shows many points of similarity; the chief difference between them is that the Hartford employs overhand stoping, and Section 21 underhand stoping. The ore at the Hartford is peculiar as to its physical character, being a little different from any hematite heretofore produced on the Marquette range. In consequence, the usual methods of mining such deposits failed to give the desired results, so that considerable experimenting was necessary in the early stages of development to find the most economical system for removing the ore.

The room-and-pillar system was tried on the 750-ft. level with but indifferent success, and was finally abandoned for the overhand-stoping and milling system modified and combined. In developing the orebody the ground broke in such large masses that it was almost impossible to keep the opening small enough so that standard sized drift sets could be used. Frequently a space of 12 or 15 ft. would open up between the timber and solid ground. As a result, a prohibitive amount of lagging had to be used, and even then the drifts were always dangerous and expensive to maintain because of the breaking of timbers and blocking of the tracks. To overcome this difficulty the openings were driven two sets high; little additional labor was required to break the ground to this increased height.



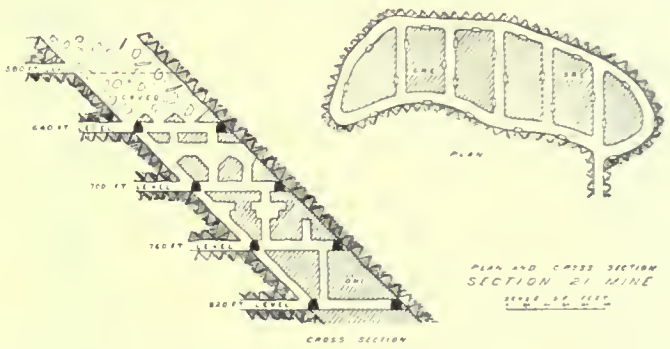
The illustration shows a cross-section through two of the stopes which were started from rises put up from a cross-cut. The stope marked N is a little farther advanced than M, in which the core has not yet fallen. No timber is used in the rises or stopes; thus no ladderways can be maintained in the openings through which the ore is milled. The working faces of the stopes are reached through the rises which are put up at frequent intervals from the foot-wall drift marked K. The stopes themselves are also connected by small drifts entirely independent of the drifts from the rises, so that there may be half a dozen or more ways of entrance or retreat. As the stopes advance, several may connect before the level above is reached. Where this happens, the conical shape is not continued, but the sides are carried up vertically instead; or one stope may be abandoned while the other is developed as originally started.

The section through the double-set drift shows a method of filling cars without using the chutes found in so many mines on the Marquette range. The caps of the lower set of timbers are lagged over to an opening in the centre directly above the track, and this opening is covered with short pieces of timber which can easily be removed to let the ore fall into a car below. When any considerable tonnage falls away at one time from the core of a stope, masses several feet in diameter must be reduced to a size small enough to pass through the opening in the lagging. With the double-set drift these masses are always accessible.

Section 21 Mine—Oliver Iron Mining Company

In the western portion of Section 21 mine a stoping system is now used which has proved both economical and safe. The physical character of the ore is such that no timber is required except for the construction of chutes for handling the product when it is drawn from the mills.

In the opening of a new level, a cross-cut is driven from foot to hanging and both are then followed until the drifts connect. Cross-cuts are usually driven between these drifts at distances of from 50 to 60 ft. Rising is started on the foot-wall as soon as development has advanced enough so that a chute can be operated without interfering with the other work on the level. The foot-wall rise is put up at this time chiefly for ventilation purposes and traveling way, as it is not needed for handling ore until later. The ideal section shows a cross-cut on 820-ft. level driven to the hanging with foot-wall rise completed, also another rise connected with the level above. Rises from the 760-ft. level show the system of milling; the dotted lines indicate the next step in advance. A floor pillar of six to ten feet is sufficient to support the level until all the available ore above it has been removed. Between the 700 and 640-ft. levels a condition still further advanced is shown, and on the 640-ft. level is shown the final stages of removing the pillars.



Practically all of the ore was removed to a depth of 350 ft. by this method without any apparent weakening of the hanging, but below this depth it has been necessary to modify the system so as to prevent caved rock from contaminating the ore. To accomplish this the pillars above the nearly exhausted level, as well as the floor pillars below it, are drilled and blasted continuously by fuse firing, with the result that the ore falls into the mills and is drawn from the chutes on the level below without any appreciable contamination.

All rises are vertical or nearly so, with the exception of the foot-wall rise and a few next the hanging. A plan of the workings just below the floor of each level, after mining has been started, would show a succession of circular mills of various sizes with a rise in the centre of each. Numerous rock intrusions and dikes make it impossible to conform rigidly to any predetermined geometrical plan further than to place rises to reach the thickest portions of the pillars on the level above. Although the drawings show four levels in operation, this is not the actual condition in practice; instead, all of the various stages of development shown in detail are worked simultaneously over different parts of one level.

VIEW FROM THE STACK AT AGUASCALIENTES SMELTER.

Mexican Labor and Its Peculiarities

By MAX J. WELCH

The mining and manufacturing interests contemplating operations in Mexico when the present war is over, are interested in the peculiarities of Mexican labor. It will not be out of place to review some of the native religious and social customs, in so far as these play an important part in the employment of labor.

To understand Mexico one must know something of its geography. Upon entering Mexico from the United States, by way of El Paso, there is a 30-hour ride by rail, due south over a sand and cactus desert. Each year the cactus grows and each dry season the wind blows sand against the cactus, until mountains of sand are formed hundreds of feet high. South of this desert country lies a tableland, from 4000 to 6000 ft. above sea-level. This tableland is the region of rich soil and fine climate that attracted Cortez and his Spanish followers in the fifteenth century. The country slopes down to the Pacific ocean upon the west and drops abruptly to the gulf upon the east. Toward the south it is mountainous. In the north-central part of this tableland is the city of Aguascalientes. This city derives its name from *agua*, meaning water, and *calientes*, meaning hot: the city being near a hot spring. Aguascalientes is the second largest city in Mexico and is also an important mining and railroad centre. Near Aguascalientes is the 'La Gran Fundición Central Mexicana,' which translated means, the great foundry or smelter of central Mexico. This smelter came into existence in the early eighties at a time when Porfirio Diaz was offering extensive inducements to foreign enterprise. It was subsequently purchased by the Guggenheims and later became one of the plants of the American Smelting & Refining Company.

When this smelter was first established it was at the request of the President that Mexican laborers were not paid more than 25c. per day. The reason given for this maximum wage scale was that the farmers paid only this wage. If the smelter paid more, the farmers would not be able to secure help in harvest time. As soon as the novelty of work at the smelter wore away, it became necessary to increase the wage scale. From time to time the wages have gradually increased until now it is often a close decision whether to use crude methods and Mexican labor or to use labor-saving machinery and American men. Along the northern border of Mexico labor-

MEXICO, SHOWING THE MEXICAN CENTRAL LINE.

saving machinery has been introduced with great success. Mexicans prove very efficient in the simple duties of attending a machine, though skilled mechanics are required to keep the machinery in working order.

Responsibility is a word that is not in the Mexican peon's vocabulary, and the meaning of responsibility is not to be taught to him. To understand why, requires knowing something of his origin. The Mexicans are a race produced by crossing the old world Spanish and the American Indian. The early Indians were a hardy type of men who lived close to nature. They knew little of responsibility. The fifteenth century Spanish were characterized by diplomacy, art, and refinement. Now, when diplomacy is injected into the Indian race, the result is a Mexican: in other words, a type that diplomatically shirks responsibility.

The possible use of the present type of Mexican is

SMELTER GATEWAY AT AGUASCALIENTES.

therefore limited to routine work. He must be under the supervision of a patient and careful foreman. The foreigner makes the best foreman, whether he be American, German, or French. The tendency is for the foreman to become soon a human 'cussing' machine. This is the case when the foreman expects too much from the Mexican, but this is unwise and unnecessary, as it can be shown that patient watchfulness, with slight losses, is more profitable in the end. To swear at a Mexican is to win his enmity. This develops his tricky and deceptive nature. In one instance the carpenter foreman had made a template of a building rafter. The Mexican carpenters had only to saw the rafters like the template. When the building was erected it developed that the Mexicans had cut every rafter a different length. This playing of tricks on the foreman by destroying lumber, holding a tape line short of the scratch line, mixing samples of ore, breaking machines to get a *siesta*, is a trait of character that will require many years to eliminate from the Mexican laborers.

There are certain people, the world over, who do not believe in the storage of human energy. Money, the representative of human energy, is to keep in circulation, not to store up. The Mexican is an advocate of this principle. To give a man of a 'circulating' disposition too much money at one time will result in making him an unsteady employee. La Gran Fundición adopted the plan of paying every day. The system is not complex and results in keeping the men at work. When the timekeeper knows the rating of each employee, it requires less bookkeeping to pay him than to enter the account.

Toward the interior of Mexico the natives are adept in the art of pilfering. All houses have iron bars over the windows to protect interior furnishings. Encircling La Gran Fundición is a high wall of adobe. During the late war this wall made the grounds a veritable fortress for the protection of foreigners. A very artistic Roman arch gateway adorns the entrance to the works. This gateway consists of three arches. It is the central arch which I wish to mention in particular. It is necessary to search every Mexican who passes out through this arch. This is done by a corps of Mexican guards. These guards look under the hat, feel over the pockets and under the belt. The material which is pilfered is not so valuable in small quantities, but a check has to be placed on the amount. The men will take belting with which to make shoes, bars of iron to trade to native blacksmiths, carpenter's tools, and almost anything they can secrete and carry.

The native Mexicans live in adobe houses which are built, as an American would say, "inside out." Adjacent to the sidewalk is a wall with windows. A front gate is attended by a servant at all times. The wealthy have inside the wall their own private court. The poor may have a colony of many families in one court and one common gate entrance. The home of a poor man consists of a room without any furniture except a bench, with a dirt floor, and a hole in the wall for a window. In cold weather they stop up the window and build a fire on the floor in the middle of the room. This system may be classified under the head of 'conservation of heat energy.'

It is difficult to change the habits and customs of a race of people. La Gran Fundición began to build a town for the workingmen according to the American system: the yard on the outside. The Company piped water into sinks and made these houses modern in every way possible. The Mexicans looked upon the project with scorn. Not one native could be induced to occupy a house built upon such unusual lines. The homes were afterward used for Chinese bunk houses.

The Mexicans wear very plain clothing, although they love bright colors. Prior to the age of two years, a child

inhabits his mother's shawl or *scrape* when out in public. About the age of three he is given a garment which in the United States would be called a shirt. The life of one of these shirts is several years. Each year the shirt shrinks some and the youth grows some: the reader only needs to draw upon his imagination to complete the story. At about the age of ten years the youth dons overalls. The older men wear hats and always carry a blanket over the shoulders. The women wear a one-piece suit resembling the garment known as a 'mother hubbard.'

In the early eighties, when Diaz was taking an interest in manufacturing and commercial enterprises for his people, he also instituted an educational system for the masses similar to that in the United States. The intention was to school the native children until some day Mexico could take its place in the civilized world. This educational system was virtually abandoned about ten years later for a reason that only students of history and religion can fully appreciate. The world has always been controlled by religion. It is a question how far the masses of the people can study a creed and not grow out of it. In Mexico the houses of worship are the same old stone churches that were built by the Spanish and Indians. There are no seats in these churches. Those who come first go up front and kneel upon the floor, and each successive person kneels behind his predecessor until the church is filled. Then they kneel upon the steps out into the street and across the road. The ringing of the chimes tells them the progress of the service.

Mexico is a country that is rich in minerals, it has a fine climate in the higher table lands, it has fertile soil and it cannot remain long as a play ground for the unprogressive. If its people will not develop their lands, others will.

Low Drill-Repair Cost on the Gogebic Range

By J. F. BERTELING

Unusually low costs for drill repairs are reported in work done at the Mikado mine, Verona, Michigan, on the Gogebic iron range, during the first half of 1914. In the first week of January 1914 the Verona Mining Co. began to sink the last 175 ft. of its Mikado shaft. For this work, four Sullivan 'Liteweight,' class 'FL-12,' 3¼-in. cylinder drills were purchased. The actual work of sinking was done with two machines, the other two being kept at hand to be used in case of break-downs or delays. The dimensions of the shaft were 8 by 16 ft. outside the timbers; a round consisted of from 28 to 32 holes, and the material was an exceedingly hard quartzite. Air was supplied the drills at 85 lb. receiver pressure.

When the work was begun, the holes were drilled to a depth of 6 ft., but as sinking progressed it was found that better results were obtained with deeper holes, owing to the tightness of the ground. The holes were therefore increased to a depth of 8 ft.; and when squaring up the bottom, when one side was too high, the holes were occasionally drilled to 9½ ft., with no apparent reduction in drilling speed. After completing the shaft, 175 ft. in depth, a pump station was cut in the quartzite, 15 by 30 by 10 ft. in size. A cross-cut 257 ft. long and 8 by 8 ft. in size was also driven in the same material. All this work was done by the same two machines that had been used in the shaft. This work took 6¼ months, during 5½ of which three working shifts were employed. The repair bill on these two drills for the above period, from January 1 to July 15, amounted to $24.09, giving a cost per machine of $1.69 per month, or of $0.015 (one and one-half cents) per cubic yard of rock excavated, the total amount being 1605 cubic yards.

So far as can be learned, this is a low record for repair cost, especially for big machines in hard rock, on the Gogebic range. A feature, in addition to the low repair bill above mentioned, that was particularly pleasing to the management, was the fact that no delays were caused by breakage of the machine, as all replacements were made while the 'muck' was being cleaned away at the end of the drilling round.

The Sullivan 'Liteweight FL-12' drill, employed on this work, represents a new development in reciprocating piston machines for mine use. The cylinders instead of being hardened and ground in the bore, are fitted with a separate steel liner whose walls are hardened throughout, and which is forced into the cylinder bore under a hydraulic pressure of many tons. At the end of the working period mentioned above, these cylinders were carefully measured, and the superintendent reported that no wear could be detected in them. The valve motion is of the familiar Sullivan air-thrown differential pattern, but the valve chest contains some new features. The valve buffers, instead of being screwed into the chest, are held in place by side rods with flat leaf steel springs at each end of the chest. The valve itself runs in interchangeable hardened steel bushings which can be replaced in a few moments if wear occurs.

A feature in these machines that met particular favor with the runners consisted in a set of ball bearings immediately under the crank handle. The superintendent stated that on the 9½-ft. holes this ball-bearing crank was of particular value. It was almost as easy for the runner to crank back the long steels as it was to handle a two-foot starter. One of the miners was curious to know what made his machine crank back so easily, and was only enlightened when he had succeeded in losing a number of the balls out of the race. In addition to the Mikado, the Castile, Eureka, Cary, Ottawa, and Montreal mines are members of the Gogebic Range group in which these drills are in use.

Ore Deposition In and Near Intrusive Rocks by Meteoric Waters

By ANDREW C. LAWSON

*In a recent number of *Economic Geology*,[1] Waldemar Lindgren has done me the honor to interpret my views on ore deposition and to dissent from them. His paper is a denial of two hypotheses which occupy the field of criticism in current discussions on the origin of ore deposits, and an advocacy of a third. This hypothesis, so ably championed by my distinguished critic, has become the favorite of most recent writers on the subject, whether they describe particular occurrences or discuss the general question. It invokes juvenile or magmatic waters, emanating directly from molten magmas, as the agency whereby ores have been deposited in or near intrusive masses. In the literature of the day almost every deposit of ore that is found to be in any way connected with igneous rocks is triumphantly explained as an exemplification of the operation of this process. So general has been the acceptance of this hypothesis that it has acquired a curious air of finality. It seems to have escaped the ordeal of criticism to which every scientific hypothesis should be subjected, not only by the skeptics but also by those who believe in its probable truth. The hypothesis is today being taught as a doctrine in texts and in lectures to the students of geology throughout the United States with as much certainty and as little question as was the doctrine of the metamorphic origin of the Archean granites thirty years ago. Many of its advocates appear to be more concerned with securing its general acceptance by the coming generation of geologists than with sifting out the evidence upon which it is based; the special pleading of the lawyer has been substituted for the dispassionate consideration of the adverse evidence as well as the favorable—for the weighing of counter-hypotheses which is the essence of scientific method. In itself the notion that magmatic waters deposit ores is fascinating and plausible, and the fact that so many eminent writers have been captivated by it is, of course, indicative of its strength as compared with other hypotheses that may be suggested to explain the same phenomena. Should it, after discussion and criticism, become a scientifically established theory to the exclusion of other hypotheses, it will undoubtedly rank high among the achievements of geological science; and those who criticize it in its formative stage will have contributed no less to its establishment than those who advocate its acceptance without criticism. But the fact that an hypothesis is fascinating and plausible, that there is much to be said in its favor, and particularly that eminent geologists teach it, does not make it a scientifically established theory. Skepticism must perform its function and exhaust itself before that comes to pass. Competitive hypotheses must be exploited. To close our eyes to them is to sacrifice our intellectual integrity. Dogmatically to deny them is to substitute for the method of science that of the church.

In my review of 'Types of Ore Deposits'[2] I advanced one alternative hypothesis which seems to be capable of explaining many ore deposits in and about intrusive masses. I said:

> The doctrine [of magmatic waters] remains feeble and can never attain to the dignity of a scientific theory until it disposes of another possible means of accounting for these ores, which has even greater claims to our attention than the supposed magmatic waters. The means I refer to is the ordinary ground-water as affected by igneous intrusion. The circulation of the ground-water would in every case be profoundly disturbed by the injection of hot igneous magmas into sedimentary terranes. The disturbance would, however, be far from chaotic. The presence of the hot body would be the controlling influence in determining the circulation. The circulation would always be upward on the periphery of the hot mass. This would be true, not only while it was still molten, but also long after it had solidified. Such a circulation of the heated ground-water would be quite competent to do all that is ascribed to magmatic waters, including the formation of lime-silicate zones. It would not only bring to a zone of active chemical reaction the materials leached from the surrounding region, but it would attack the still hot, though solid, igneous mass itself and abstract from it part of its metallic constituents. And it is significant in this connection that most of the igneous rocks that have ores either on their periphery or within their mass have been subject to very severe chemical attack. Until this very probable means of ore deposition at the contact of limestone and igneous rocks has been disposed of, the doctrine of magmatic waters is unnecessary. It remains at best a possibility, one of the fashionable vagaries of our time, not entitled to respect as a scientifically established theory.

Mr. Lindgren's quotation of part of the last sentence of this statement fails to make my position clear, and as he combats the hypothesis which it expresses, I feel constrained to reproduce the statement in full, as the text of following discussion. His hope that I have already changed my view of this question is not yet realized; and the present paper is intended not only as a reply to his strictures upon the alternative hypothesis, as above stated, but also as a further exploitation of its possibilities. My only positive view in the matter is that the deposition of ores by magmatic waters as a general scientific theory is not yet established. I shall be glad to accept it as such when its advocates shall have fulfilled

*[At the New York meeting of the American Institute of Mining Engineers last February there was a most interesting symposium upon the genesis of ore deposits. In the course of it Mr. Lindgren criticized views of Mr. Lawson, originally published in the *Mining and Scientific Press*. In reply Mr. Lawson has published in the *Bull.* Geol. Dept. Univ. California, Vol. 8, No. 9, a complete review of the subject of ore deposition near intrusives by meteoric waters, from which this extract is taken.—EDITOR.]

[1]Vol. IX, No. 2, April 1914.

[2]*Mining and Scientific Press*, February 3, 1912.

the usual scientific requirement of disproving opposing hypotheses. I agree with Mr. Lindgren's statement[3] that there are "three possible methods of deposition: (1) by atmospheric waters heated by contact with the cooling porphyry; (2) by ascending magmatic waters; or (3) by a mixture of both." But inasmuch as meteoric waters are known to have deposited many important orebodies in situations where there is no suggestion of magmatic emanations, I am inclined to the view that they may discharge the same function even more efficiently as a consequence of intrusion; and I am, therefore, more impressed by the probability of the first of these three possibilities than by that of the second. In assuming the rôle of critic of the more popular explanation of ore deposition I do not, of course, venture to hope that Mr. Lindgren will change his view as a result of my remarks; but I shall be more than content if I succeed in convincing the younger geological students of this country that the origin of ore deposits in or near intrusives is still an open question and that further observations, made in the light of alternative hypotheses, are necessary before we can arrive at a settled theory.

Lindgren's Criticism

The circulation of ground-water.—The phase of the question which Mr. Lindgren deals with particularly is the origin of garnet zones and associated ore deposits at the contact of intrusive rocks with limestone. He says: "These deposits are high-temperature deposits. * * * The lowest temperature at which garnets, diopside, etc., may form is about 400 or 500°C. * * * It devolves upon the supporters of the view set forth to explain the possibility of such a circulation upward along the contact at temperatures of from 300 to 1000°C. The Daubrée experiment will really not suffice any more as an explanation."

In reply to this I may say, first, that I have never invoked the Daubrée experiment to explain the upward circulation under the conditions discussed, nor have I ever considered that the Daubrée experiment, the inferences drawn from it by various writers, or the exposition of the fallacy of these inferences by Johnson and Adams[4] as in any way affecting the question at issue. The question is: Is it possible for the ground-water of stratified rocks, assuming its presence, to circulate upward in the heated zone peripheral to an intrusive mass, or through the mass itself if the latter be rendered permeable by fracture? I understand from Mr. Lindgren's remarks just quoted that he considers this impossible, or at least that he is very skeptical as to its possibility; although he apparently regarded it as possible when he wrote his monograph and folio[5] on the Clifton-Morenci district. If he now denies the possibility of such upward circulation, it is easy to understand why he adopts the hypothesis of magmatic waters as the only one explanatory of the origin of such contact deposits. It behooves me therefore to demonstrate this possibility. I will first, however, disclaim the belief, which I fear will be imputed to me if I do not anticipate the imputation, that the sedimentary rocks of the earth's crust everywhere contain similarly large quantities of water. The water in rocks is very unequally distributed and is in general more abundant in the superficial portions of the crust than in the deeper, though under certain conditions this relation may be reversed as, for example, in certain artesian basins. The inequality of distribution is, however, due to the variation in size or in prevalence, or both, of the voids in the rocks. In some rocks, such as shale, the voids may be so small and the movement of the water through them may be so slow that in an excavation they may appear to be dry. Thus, in certain coal mines beneath the sea, where the coal seams lie between beds of shale, the workings may be so dry as to be dusty. The escape of water from the shale is less than can be evaporated. Nevertheless all sedimentary rocks below the water-level are saturated to an unknown but great depth. But saturation does not imply an abundant flow to a conduit or fissure. The rate of flow from rocks in the direction of negative pressure is a function, not of the percentage of volume occupied by water, but of rock texture as expressed in the size of the voids in which the water is held. With the increasing pressure that comes with depth and as a result of cementation, these voids diminish in size, thereby decreasing the proportion of water which the rock is capable of holding as well as the rate of flow. But making all allowance for this diminution of storage capacity there is a vast quantity of water contained in the sedimentary rocks in their unaltered state at all depths; and at high temperatures, which are an essential condition of our problem, the rate of flow and therefore the rate of escape to fissures, etc., is undoubtedly greatly accelerated. Moreover, brittle rocks such as quartzite, sandstone, and limestone, which have been folded and otherwise disturbed, are usually traversed by fractures, faults, and joints, and these, together with the partings of stratification, afford comparatively free access of surface waters to the limit of the zone of fracture for such rocks. That limit for strong rocks is very much deeper than C. R. Van Hise[6] would have us believe, as we know from the experimental work of F. I. Adams.[7]

Now, for the purpose of demonstrating the possibility which Mr. Lindgren denies or doubts, we may assume that an intrusive mass has invaded a syncline of sedimentary strata, including limestone, within the zone of fracture for strong rocks. As a mechanical consequence of a sudden intrusion the structure of the encasing rocks will be disturbed or modified. If it be a sill it will lift the superincumbent strata and there will be stresses and ruptures inaugurated on its margin. Radial ruptures may be

occupied as dikes; tangential ruptures may escape such occupation. The lifted strata may be broken into blocks faulted against one another.[8] If it be a plano-convex laccolith, besides similar stresses and ruptures there will be distension of the overarching strata in a central position. If it be a steep-sided laccolith, the tendency to peripheral tangential rupturing will be pronounced and effective. If the intrusive mass, on the other hand, make its way slowly into the syncline by a process of stoping or resorption or both, there may be a certain amount of shattering and faulting of the sedimentary rocks on its periphery.[9] These results of the intrusive act, in so far as they fracture the encasing rocks, provide channels for the subsequent circulation of vapors and waters, but their efficiency as conduits may for a time, particularly at the immediate periphery of the intrusion, be greatly reduced by the expansion of the encasing rocks due to rising temperature.

Probably a more important development of conduits for the circulation of vapors and water is that which follows the solidification of the intrusive mass by reason of the shrinkage due first to crystallization and then to subsequent loss of heat. Such shrinkage would give rise to stresses that could be relieved only by distensional fractures, many of which would doubtless be partly sealed by normal faulting and the gouges thereby produced. That such shrinkage cracks are important features of cooling igneous masses and may become the conduits of water circulation and ore deposition is being freely recognized in recent years, notably by L. V. Pirsson,[10] W. H. Weed,[11] Joseph Barrell,[12] W. G. Miller,[13] and J. B. Tyrrell.[14] It is to be noted that such shrinkage cracks are not confined to the encasing rocks of the intruded mass, but may equally well affect the igneous rock itself; although it is probable that the fracturing is begun beyond it by collapse due to crystallization.

Certain veins in volcanic rocks in Nevada, which came under my observation a few years ago, I ascribed in an unpublished report to shrinkage by cooling of an intrusive mass. The temperature of the region in which shrinkage cracks should begin to form would be but little less than the melting-point of the magma, and therefore well above the lower limit of the range specified by Mr. Lindgren. The necessary conduits and temperature being thus provided, we may proceed with the question of circulation. (Illustrated by diagram not reproduced here.) It is apparent that water entering on the outcrop of tilted beds and following the stratification will tend to keep the lower part of the syncline saturated. The intrusive mass provides conduits transverse to the stratification, initially by disruption and subsequently by shrinkage, and it also creates a high temperature in the rupture zone. If the temperature were uniform throughout the region that is concerned, the movement of the water would be up through these conduits on the artesian principle. If the temperature at the contact be high and that at the outcrop be low, the artesian principle operates *a fortiori,* a short column of superheated steam being lighter than a long column of water. As the steam is drawn off above the contact the supply is replenished from the inlets, so that a prolonged circulation is maintained. If the suppositious magmatic waters can rise at the contact there is no reason why the real meteoric waters should not do so also. It seems to me, therefore, that it devolves upon the supporters of Mr. Lindgren's view to explain the *impossibility* of such a circulation upward along the contact at temperatures of from 300 to 1000°C. The Daubrée experiment has nothing to do with the case. But the zone of rupture due to shrinkage is not confined to the region exterior to the intrusion. The latter is itself affected by the process as well as by faults due to less local stresses. The igneous rock becomes sheared and dislocated, so that the meteoric waters in the underlying strata have access to its interior, rising at high pressure and at high temperature through its lower part where the magmatic sulphides abound. The igneous rock may thus be leached of a portion of its metallic content and supply the minerals for deposition in the fissure-replacement or contact-replacement veins above, either in the igneous mass or in the encasing rocks.

Lateral movement of the circulation.—In an effort "to make the real position of the leaching theory a little clearer," Mr. Lindgren states his second objection as follows: "The metals, etc., were extracted from the intrusive rock, that is, from a hot body having a temperature of from 500 to 1500°, and deposited in the adjacent, cooler sediments, say at temperatures from 300 to 1000°C. Consequently the circulation of the atmospheric waters would really take place in a lateral direction and not simply along the contact as maintained by Mr. Lawson." I am somewhat at a loss to answer this objection. It seems so trivial that I fear my critic has not fully expressed himself. I have stated that "the circulation would always be upward on the periphery of the hot mass." But this surely does not preclude a horizontal component of motion in the zone of upward circulation. The term circulation implies that. I see no difficulty in the conception of the rising meteoric waters permeating the hot igneous mass, both from its limiting surface and by way of fissures traversing it, and carrying silica, iron, salts of the ore metals, etc., to (1) positions in the upper cooler parts of the mass, as may very possibly have been the case at Butte,[15] (2) higher positions on its contact with the adjoining rocks in the fashion advocated by G. F. Becker[16] for the Comstock,

or (3) higher positions within the encasing rocks, as may well have been the case at Bisbee or Bingham. That the waters in their upward circulation should also move laterally goes without saying. It may be also again noted that the waters thus coming in contact with the hot igneous mass would not be wholly dependent upon it for the supply of mineral matter. The sedimentary rocks would also yield their quota.

Deposition of ores in inclusions and salients.—Mr. Lindgren's next objection is that "ores are generally found at limestone points projecting into the intrusive mass or in slabs of limestone swimming in the igneous rock. It is difficult to see why the circulating atmospheric waters should seek such places by preference. In many deposits there is no evidence of fractures or paths which could have been followed by the water." Here my critic leaves the *a priori* method of attack and descends to the safe field of observation, where of course he is very much at home. It is to be regretted, however, that he did not cite some specific instances of ores formed in inclusions in igneous rock. That ores may occur in slabs of limestone swimming in igneous rock I do not deny, but it is incumbent upon Mr. Lindgren to show that the ore was not formed when the slabs were an integral portion of the invaded country and before they were subsequently torn off and engulfed as inclusions as the irruptive process advanced. The same inconclusiveness inheres in the statement as to ore being generally found at limestone points projecting into the intrusive mass. An intrusive mass as it invades a limestone country by stoping or resorption encroaches upon the zone which may have previously been the seat of ore deposition and so may bring mineralized points into the transgressive contact. This explanation involves, of course, the possibility of the garnet zone and some of the ore associated with it having been formed by circulating heated waters during the intrusion, if the latter be a single act. But until such occurrences are particularized I shall be inclined to doubt their generality and to regard them as exceptional. The *general* condition appears to be that the ores were formed after the consolidation of the intrusive mass. Thus Joseph Barrell,[17] speaking of the ores at Marysville, says:

> Some little time elapsed between the solidification of the batholith and the opening of the vein fissures, since not only had there been a period of aplitic and pegmatitic injections, but a number of later intrusions of porphyry had occurred previous to the formation of the vein fissures. It would appear probable, therefore, that the fissure veins, if indeed they are contraction effects, belong not to an initial stage but to the final stages of cooling.

At Butte the quartz-monzonite had solidified and it was traversed by two distinct intrusives, the first aplite and the second quartz-porphyry, before the veins were formed:

> The vein and fault-fracture systems intersect the granite, aplite, and quartz-porphyry dikes alike, and all these are similarly affected by the general alteration processes accompanying later vein formation.[18]

Again, Emmons has said:

> In the Wasatch the orebodies found at the points of actual contact of country rock with eruptive masses have not proved to be so important economically as those which lie at some distance from the contact zones and have no evident and direct connection with them.[19]

At Bingham the descriptions which Arthur Keith and J. M. Boutwell[20] have given us afford no warrant for the statement that the occurrence of ore at points of limestone projecting into the intrusive mass is a general phenomenon. Neither do I find such occurrences described in the most valuable memoir on the Clifton-Morenci district[21]; but I do find that important orebodies occur in fissures in the porphyry, and the evidence that these are of later age than the ore in the metamorphic contact zone is not conclusive.

> Fissures and extensive shattering developed both in porphyry and altered sediments after the congealing of the magma and these fissures and seams were cemented by quartz, pyrite, chalcopyrite, and zinc-blende, forming normal veins largely of the type of replacement veins.* * * As far as the metallic minerals are concerned, there is a striking similarity between the veins connected with the porphyry and the contact metamorphic deposits. * * * A relationship is also clearly seen in the remarkable action of the vein solutions on the adjoining wall rock wherever this is limestone, tremolite, and diopside being formed by metasomatic action. On the whole, iron and silica are the main substances added during contact metamorphism as well as during vein formation.[22]

If, then, the waters that formed the fissure veins at a period subsequent to the consolidation of the porphyry laccolith replaced the limestone walls by tremolite and diopside, why may not the contact deposits have been also formed by similar late waters? And what ground is there for rejecting so absolutely the possibility that these were meteoric waters heated by the cooling intrusion?

It would seem, therefore, that the assertion regarding the generality of the *formation* of ore in included slabs and projecting points of limestone requires some elaboration and specification before it can become an argument either for the hypothesis of magmatic waters or against the hypothesis of meteoric waters. The failure of "evidence of fracture or paths which could have been followed by the water" applies equally well to magmatic as to meteoric waters, and is of little moment when we [illegible] that the water in either event was probably in the form of superheated steam.

Hydrothermal attack.—Mr. Lindgren's next objection is stated as follows: "Inevitably, such a hydrothermal circulation as is suggested by Mr. Lawson would result in a strong alteration of the intrusive. In many in-

[22] *Op. cit.*, pp. 219-220.

stances there is no such evidence of replacing solutions. Fresh granite rock often borders the ore."

The obvious answer to this objection is of course that, in so far as it is a fact, magmatic waters escaping from a magma constitute a hydrothermal circulation no less than meteoric waters locally heated, and that where they traverse the solidified intrusion, as is so often assumed, they must also equally inevitably cause a strong alteration of the rock. When this is found not to be the case, as Mr. Lindgren states, there must be something wrong with the hypothesis of magmatic waters. But, as a matter of fact, in those cases in which the waters responsible for ore deposition are known to have traversed the igneous rock, as for example, at Butte and at Clifton-Morenci, there has been a notable amount of hydrothermal alteration; and the whole question at issue is whether this water is magmatic or meteoric in origin.

Thermal and reactionary metamorphism.—Finally, Mr. Lindgren dissents from any attempt to discriminate between thermal metamorphism and reactionary metamorphism at the contact of intrusive rocks. Thermal metamorphism I consider to have been proved experimentally by the conversion of chalk into marble by heating in a sealed chamber[23] and also to have been proved inductively by Rosenbusch's studies at Barr-Andlau.[24]

Reactionary metamorphism may be freely recognized without admitting that it is responsible for the deposition of orebodies, particularly those occupying fissures in the irruptive mass which produces the metamorphism. Emanations from magmas are not denied and certain of these by reaction with the encasing rocks give rise to the deposition of minerals which are rather characteristic and different from those of the ore deposits in question.

It thus appears that Mr. Lindgren's criticism of the brief expression of my views, appearing in the review of 'Types of Ore Deposits,'[25] has not overthrown the hypothesis which I there advanced; nor has it weakened my position, which is that much of the argument in favor of magmatic waters applies equally well to the hypothesis of meteoric waters, that the question of the origin of contact deposits is an open one, and that our students should know it is open.

Kemp's Criticism

Association of ores with fissures.—In a recent paper[26] J. F. Kemp, in referring to my suggestion that meteoric waters under the influence of heat given off by intrusives may be the agency whereby the ores of contact zones are formed, states that:

> In general, although not invariably, the formation of the silicates seems to precede that of the magnetite and the sulphides, but they all are believed to belong to one process. The sulphides are irregular in distribution, and so far as recorded descriptions go, *they do not seem to be associated with faults or other nourishing waterways through which they might have entered after the contact effects had been produced.*

In reply to the part of this statement which I have italicized I call Mr. Kemp's attention to the ores at Butte which occur in fissures, to the ores at Bingham which occur either in fissures or associated with fissures, to the fissure lodes at Morenci in the porphyry, to the ores of Marysville in fissures, and to the ores at Matehuala, all of which are ascribed to magmatic waters, that have reached the places of deposition by ample waterways. If the presence of fissures is all that is needed to negative the hypothesis of magmatic waters it surely fails in many cases where it has been applied. But even if fissures and other nourishing waterways were lacking, the objection is singularly feeble, for if the waters from the magma can make their way through the rocks and promote chemical reactions, there is no reason that I can imagine why the equally hot meteoric waters should not do the same. The only other objection that Mr. Kemp urges against the possibility of meteoric waters doing the work which he ascribes to magmatic waters is that "the wellnigh unanimous concensus of opinion of those who have studied the zones has been that the metallic minerals go along with the others in method of introduction" and "despite Mr. Lawson's strictures, the general testimony favors essentially pneumatolitic methods." I am aware of the "concensus of opinion" and the "general testimony," but I fail to see that it proves anything scientifically. I have great respect for the gentlemen who hold this prevailing opinion, but I can have no great respect for the hypothesis which it embodies until the alternative one of meteoric waters is negatived somewhat more definitely than by Mr. Kemp's method of quoting opinions.

Knopf's Criticism

Paragenesis of tourmaline and ore.—In a recent paper[27] I pointed out that the commonly accepted view, which refers the deposition of the copper ores at Butte to magmatic waters, is not the only possible explanation of their origin. If the quartz monzonite of Butte be regarded as a laccolith resting on a floor of sedimentary rocks, which have sagged below it in synclinal fashion, then the deposition of the ores may be ascribed to the ascent of meteoric waters through fissures traversing the hot mass. These waters would pass through and leach the zone of magmatic sulphides at the base of the laccolith and deposit the salts of the metals thus obtained at higher and cooler levels. A. Knopf has recently reviewed[28] this paper in a most kindly and appreciative spirit. I accept his correction that there is evidence of a certain amount of doming of the roof, though this is so slight that it still leaves us under the necessity of recog-

[28] *Econ. Geol.*, Vol. 9, No. 4, pp. 396-402.

nizing a sag of the floor to accommodate the intrusive mass. Mr. Knopf intimates that I have not given due weight to his argument in favor of magmatic waters based on the paragenesis of tourmaline and ore, taken in connection with the concentration of the former in the aplitic magma. I may also admit this charge without blushing, but after further reflection I am still not satisfied that the argument is entirely convincing. It may be conceded from Mr. Knopf's observations and those of Ward and Granigg which he cites that the tourmaline is a concentration product in the residual magma. But is it not possible that after consolidation such concentrations of tourmaline may, in a laccolith which has been broken by faults, be open to the attack of superheated steam rising from below, and so be taken into solution again together with salts of the metals obtained by attack upon the earlier precipitated sulphides? If the sulphides remained residual with the constituents of the tourmaline and the waters escaped directly into fissures carrying both sulphides and tourmaline, I should expect to find besides the veins some rather remarkable tourmaliniferous dikes rich in sulphides following similar fissures. I am free to admit, however, that the evidence adduced by Mr. Knopf has more weight than most of that which is urged in favor of the hypothesis of magmatic waters.

[Following this, Mr. Lawson presents some general remarks upon the relation of laccoliths and batholiths to ore deposition and reviews the occurrence of ore at Butte, Bingham, Ely, Bisbee, Clifton-Morenci, and Cananea, showing that in each case there is evidence of the ores having been formed in a structural syncline. Such occurrence is believed to favor their origin through the stimulation of the circulation of ordinary underground waters by the intrusion of heated rocks.—EDITOR.]

THE MINERAL PRODUCTION of Virginia increased in value from $14,995,842 in 1912, to $17,178,580 in 1913, according to the U. S. Geological Survey. The following were the chief products:

Mineral.	1913.	Value.	1912.	Value.
Coal, tons	8,828,068	$8,952,653	7,846,638	$7,518,576
Pig iron, tons	380,508	5,310,167	328,961	4,364,708
Coke, tons	1,303,603	2,840,275	967,947	1,815,975
Clay products	.....	1,705,651	.....	.....
Quarry products	.....	1,063,782	.....	877,746
Iron pyrite, tons	148,259	587,041	.....	.....
Soapstone, tons	26,487	615,558	25,313	576,473
Mineral waters, gal.	2,873,288	298,473	.....	.....

Virginia also produces asbestos, barytes, cement, copper, feldspar, occasional gems, gold, gypsum, infusorial earth, mica, millstones, mineral paints, salt, sand and gravel, silver, slate, and zinc.

MINERAL OUTPUT of Queensland, Australia, for the second quarter of 1914 was £460,274, a decrease of £43,375, due mainly to silver, tin, lead, and wolfram. For the half-year the total is £137,832 behind that period of 1913. Gold output for seven months was 135,578 oz., a decrease of 20,853 ounces.

Sampling and Assaying Cobalt Ores

Sampling and assaying rich silver ores of Cobalt, Ontario, have recently been discussed by members of the Canadian Mining Institute. According to A. M. Smoot of New York, results from samples crushed, rolled, trammeled, mixed, shoveled, cut from ridges of ore, reduced by riffles, further crushed, coned, and divided, and finally ground through 100 mesh, metallics being separated and assayed alone, are excellent. The following table shows how close several samples agreed by assay:

	Silver, ounces per ton.				
	A	B	C	D	E
No. 1	2269.7	2082.8	1527.7	535.8	353.3
No. 2	2263.6	2079.2	1533.0	538.5	355.1
No. 3	2260.7	2072.6	1528.6	540.1	358.6
No. 4	2267.2	2080.4	1526.2	544.5	355.1
Average	2265.3	2078.8	1528.9	539.8	355.5

For rich ores the scorification assay is sometimes used at Cobalt, one-tenth assay-ton being taken, but furnace conditions affect the results. A better method is the combination assay, which yields higher results and more concordant than can be attained by any all-fire process, and is acceptable to smelters. In this assay a ¼ or ½ assay-ton of the sample is weighed, and 75 to 100 c.c. of strong nitric acid added in beakers until frothing is finished. The solutions are heated on a steam bath until red fume ceases, when they are diluted with 200 c.c. of distilled water, and allowed to stand over night. Certain points are to be observed during this procedure, and insoluble residue is fused in scorifiers or crucibles, and a lead button obtained. The cold solutions are next filtered, and to the filtrate is added standard sodium chloride solution to precipitate the silver as a chloride. The precipitate is transferred to a filter and washed slightly. The filters are then put in scorifiers which have been glazed on the inside by melting litharge in them, and pouring off the excess. This is to prevent the porous scorifier from absorbing moisture from the filter paper. As further protection, a small disk of pure sheet lead is placed under the paper. The charge is now dried, and the paper charred in an oven heated to 250 to 300 C. Fine test lead is sprinkled over the dried chloride, and buttons from insoluble residue are added. Scorification in a muffle is conducted at a low temperature so as to obtain 15-gram lead buttons. Care must be taken to avoid spitting at the end of cupellation. Bismuth in Cobalt ores is a source of irregularity and it should be dealt with during the solution period. In ¼ assay-ton charges, samples assaying 3293.1 oz. per ton do not vary over 6 oz., and many check exactly; and in ½ assay-ton charges, samples with 274.5 and 962.8 oz. per ton were more even. Four assays are made of each individual sample. Metallic scales are assayed separately by the all-fire assay.

MANGANESE DEPOSITS of promise occur in several places in Page and Rockingham counties of Virginia, according to M. A. Rowan in the *Manufacturers Record*.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Milling in Cyanide

The Editor:

Sir—Mr. A. W. Allen's suggestion in his discussion under the above head in your issue of September 9, that I had criticized the ultimate results of the Dome milling practice in my remarks published in the July 4 *Press*, is quite without foundation. In a previous discussion he instanced comparative data on the performance of the Dome and Hollinger mills which were inaccurate with regard to the latter. I merely corrected his data and pointed out that upon his own line of reasoning the correct figures reversed his argument. Had he carefully read Mr. Megraw's articles from which he quoted, he would have noted that it was specifically stated that the Hollinger was just starting up at the time of writing, and milling data were still only vaguely indicative. No experienced metallurgist should have been misled, and corrections were palpably not in order. Mr. Allen included '% extraction' in his comparative tabulation, and my tabulation was merely a correction of the data as far as it referred to the Hollinger.

Mr. Allen goes on to state that in practice, precipitation ratio is not proportional to grade of ore. Presumably he can cite facts to prove his point. In my notes under a date about two years back, I find the following tabulation which directly bears upon this point:

Mill and location.	Mill heads.	Precipitation ratio.
Mogul (Pluma plant), Black Hills	$ 4	1.25
Lundberg, Dorr & Wilson, Black Hills	6	1.5
El Tigre, Mexico	8	2.5
Esperanza, Mexico	10	2.5
Tonopah Mining Co., Nevada	20	5.0
Belmont (Millers plant), Nevada	20	5.0

An examination of this table shows that in these well known and representative mills precipitation ratio varies almost exactly with grade of ore.

Mr. Allen states that milling in water is impracticable unless the pulp is dewatered before cyaniding to "within a few percentages of moisture contained in discharged residues." I should say that 40% moisture is about as low as this dewatering can economically be carried. At 40%, 0.67 tons of water per ton dry will go into the cyanide treatment with the pulp. If the residues are thickened by decantation before discharging, about 40% would be the final moisture and no water wash could be given without building up solutions. In that case cost of dewatering ahead of cyaniding and cyanide loss due to no water wash on tailing must be charged against milling in water as against milling in solution. Also more tons of barren must be used in washing than would be required of barren plus water had milling been in solution—hence increased precipitation. If any form of filtration is used the moisture in residue will be considerably lower than 40%, and not only can no water wash be employed, but waste solution must result. I am gratified to learn that Mr. Allen disapproves of waste solution, and wait with interest a further statement as to just how he expects to avoid it when milling in water.

Timmins, Ontario, September 13.

As an interesting commentary on the remarks above I add the following excerpt from a letter received today from W. D. Alderson, general manager for the Mother Lode Sheep Creek Mining Co. The italics are mine. Mr. Alderson says: "We switched our system of milling from stamping in water and amalgamation to stamping in solution followed by continuous decantation and filtration, with the result that we *cut down on our consumption of cyanide by one-half* with a *greater saving*. We also precipitate a *smaller tonnage of higher grade solution*. This gives us a high-grade product, $40 to $50 per pound, giving bullion 750 fine by direct melt."

Noel Cunningham.

Timmins, Ontario, September 23.

Titration Results and Solution Control in Cyaniding

The Editor:

Sir—Having read A. W. Allen's article on titration results in the *Press* of August 15, in which he states that the methods used by him in obtaining his titration results were those described by him in an article also in the *Press* of September 20, 1913, which I have carefully studied, I think that his free cyanide and zinc double cyanide results given in his article of August 15 are not correct.

In determining free cyanide, Mr. Allen says that he first determines the 'total cyanide' by adding an excess of caustic alkali, then titrating the sample to a yellow opalescence with silver nitrate, using a potassium iodide indicator. In another sample he determines the protective alkalinity by adding potassium ferroeyanide, and a slight excess of silver nitrate over that required in the total cyanide determination, and titrating with N/10 HNO_3 in the presence of phenolphthalein, to the disappearance of the red coloration. And then determines the free cyanide in a third sample by adding N/10 acid till the protective alkalinity is neutralized,

that is the amount of N/10 acid shown necessary in the preceding test, and titrating the neutralized sample for free cyanide by means of silver nitrate in the presence of potassium iodide, using the yellow opalescent end point. That this method is doubtful may be proved by the following:

In the first step of Mr. Allen's method, where he adds caustic alkali before titrating for total cyanide, the following reactions would occur:

$$(1)\quad 2KCN + AgNO_3 = KAg(CN)_2 + KNO_3$$

$$(2)\quad K_2Zn(CN)_4 + 4KOH + 2AgNO_3 = 2KAg(CN)_2 + Zn(OK)_2 + 2KNO_3 + 2H_2O$$

In the tests for protective alkalinity he does not add any caustic alkali, but adds the same amount of $AgNO_3$ to it before titrating for protective alkalinity, as he added to his test for total cyanide. If his solution contained no protective alkalinity, the following reactions in the case of $K_2Zn(CN)_4$ would occur on the addition of the same amount of $AgNO_3$ as was added to his total cyanide test:

$$(3)\quad K_2Zn(CN)_4 + 2AgNO_3 = 2AgCN + Zn(CN)_2 + 2KNO_3$$

But if the solution contained some protective alkalinity, though not sufficient to supply the alkali necessary for the reaction No. 2, the results of adding the amount of $AgNO_3$ found necessary for the total cyanide would be the formation of more or less alkaline zincate, according to the amount of caustic alkali contained in the original solution. The alkaline zincate formed by the addition of silver nitrate, according to equation No. 2, only possesses a protective alkalinity toward phenolphthalein, equal to half of that which was possessed by the caustic alkali consumed in the reaction No. 2 which resulted in its formation. (In his article on solution control, Mr. Allen states that, on adding a caustic alkali to a neutral potassium zinc cyanide solution the result should be an increase of the sum total alkalinity to phenolphthalein, and a decrease to methol orange. This is incorrect, as $K_2Zn(CN)_4$ gives only 7.9% alkalinity to phenolphthalein, while it gives 100% alkalinity to methol orange.) In making his total alkalinity determination, using phenolphthalein, the addition of acid first neutralizes the caustic alkalies, then the loosely combined alkalies [the K in $Zn(OK)_2$], when the protective alkaline contents of the solution have been sufficiently neutralized by the acid, the cyanide in the solution immediately combines with the zinc which existed originally in the solution as an alkaline zincate, forming potassium zinc cyanide, which, as previously mentioned, only gives 7.9% alkalinity to phenolphthalein. Therefore, the alkalinity of the solution toward phenolphthalein would be balanced, excepting for the increase due to the 7.9% of the alkalinity of $K_2Zn(CN)_4$ by the addition of four molecules of caustic alkali to one molecule of alkaline zinc cyanide.

In cases wherein solutions contained sufficient alkalinity to cause all of the zinc to be held in solution as a zincate of an alkali, Mr. Allen's methods would give low results in free cyanide, and his protective alkalinity would be high. (In making this statement regarding protective alkalinity, I may mention that I do not consider alkaline zincates as true protective alkalies, for if they were neutralized with acid the resulting zinc hydrate would immediately combine with any free cyanide present to form zinc double cyanide, which would not be available for extraction purposes, unless it should be treated with a caustic alkali.) The reason for the low results in free cyanide obtained by Mr. Allen's method is, that in neutralizing his solution with acid he neutralizes the alkalinity which protects and holds the zinc in solution as a zincate, as may be expressed by the equation

$$Zn(OK)_2 + 2HNO_3 = Zn(OH)_2 + 2KNO_3$$

forming zinc hydrate, which combines immediately with free cyanide to form an alkaline zinc cyanide according to the reaction

$$Zn(OH)_2 + 4KCN = K_2Zn(CN)_4 + 2KOH$$

which alkaline zinc cyanide does not show by the silver nitrate titration in the neutral solution any considerable portion of the free cyanide, which was consumed in dissolving the zinc hydrate formed by neutralizing the protective alkalinity of the solution, by means of acid, prior to the titration for free cyanide. Therefore, any free cyanide which the solution contained before it was neutralized and which combined with the zinc hydrate during the neutralizing of the solution is not shown as free cyanide by the method which Mr. Allen uses. It is probable that his methods would be approximately correct for free cyanide when applied to solutions containing little or no protective alkalinity, but they would vary in their accuracy accordingly as the protective alkalinity varies.

My statements herein relative to the accuracy of Mr. Allen's methods have been proved to some extent by E. M. Hamilton's article on solution control in the *Press* of July 25, 1914. The fifth and sixth series of titration results there printed clearly show the value of my statements.

There is no doubt in my mind regarding the form in which zinc exists in cyanide solutions. I am absolutely certain that it can and does exist in some working solution wholly as a zincate, while it may exist in other solutions either as a double cyanide or a mixture of double cyanide and a zincate.

Mr. Allen does not prove that zinc does not exist in solutions as a zincate of an alkali, nor does he prove that there is no regeneration of free cyanide when the alkaline zinc cyanide is acted upon by an alkali, although he attempts to prove in his article on solution control that a regeneration did not occur in his tests. While his tests did not show a regeneration of free cyanide, nevertheless there was undoubtedly some regeneration which was not shown through the fault of the methods used by him.

HARRY R. LAYNG.

San Francisco, August 18.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

STEEL RAILS weighing 120 lb. to the yard, and the largest made for any line in the world, are to be laid and tried by the Pennsylvania Railroad Co. on its Pittsburgh division, near Altoona, where traffic is heavy.

PUMPING ENGINES at the Parramatta sewerage works, a suburb of Sydney, New South Wales, are being successfully run by sewer-gas power. The new power is more effective than coal gas, and is considerably less expensive.

THE VISCOSITY OF WATER decreases with rise in temperature. This fact may be made use of in connection with the settlement of slime. The operation is hastened in some installations by the preliminary heating of the battery water with exhaust steam or other means.

SAFETY-WORK DEPARTMENTS are now maintained by practically all the iron-ore mining companies of the Lake Superior region. The cost of such work varies greatly, but it may be said that during the year in which safety devices are installed, it may be as high as $10 or more per man employed; but a fair average for maintaining the department, after preliminary work has been done, would be about $5 per man.

GASOLINE LOCOMOTIVES are used in mines for haulage purposes, but care must be taken to provide plenty of air to dilute the exhaust in drifts, so as not to cause discomfort to miners. Both carbon monoxide and carbon dioxide are produced by the engine, varying in quantity, according to good or bad carburation. For each cubic foot of carbon monoxide possible to generate in the engine, there should be available 2000 cu. ft. of air to mix with the exhaust gases if the air is for continued breathing.

CYANIDE CONSUMPTION FORECASTS should be based on titration tests made before experimental ore treatment, and after treatment and precipitation of the contained gold and silver. The estimation should be checked by comparison with the actual amount of cyanide required to re-standardize the solution. Such tests are preferably carried out in series, the re-standardized solution being used again for fresh extraction tests. By this means any ill-effects on extraction or precipitation which may result from the accumulation of precipitant salts in the solution will be noticed and the scheme of treatment regulated accordingly.

GRAPHITE in ores has interfered with cyanide treatment at several gold mining districts of the world. At Gympie, Queensland, Australia, there are several large heaps of tailing assaying about $2.50 per ton, but no serious attempt has been made to treat them. The Scottish Gympie Co. has two dumps of tailing, one of 60,000 tons or more, and mostly graphitic, and a smaller lot of 20,000 tons of what is called Inglewood tailing, derived from the Inglewood vein, which runs at right angles to the main lode series. The tailing is white and contains no graphite, and is particularly amenable to cyanide, the only consideration being the degree to which it is ground. The graphitic tailing, on the contrary, is not suitable for cyaniding, only yielding 40% or so after complete sliming. W. Macdonald, who studied the problem there for a year, came to the conclusion that this poor extraction by cyanide was not due to premature or re-precipitation of the gold. On mixing the two classes of tailing, and subjecting the mixture to cyanide solution, and comparing the results with the results of similar tests carried out on each class separately, he found the extraction on the clean Inglewood tailing was just as good as when treated separately, showing that the graphite had not caused precipitation of the gold dissolved from the Inglewood ore. There is no chemical difficulty in treatment and the consumption of cyanide in both cases was abnormally low. A characteristic feature of the graphitic tailing is its yield of gold to amalgamation. By grinding very fine, practically all-sliming, an extraction of upward of 70% of the gold resulted. The proportion of gold to silver is about 5 to 3, and it is likely that they exist in the form of an alloy.

GOLD OUTPUT of the Lena Goldfields property, Siberia, from October 1, 1913, to July 20, 1914, was as follows:

OLD-TYPE WASHING MACHINES, LENA GOLDFIELDS, SIBERIA.

gravel mined, 651,687 cu. yd.; gravel washed, 524,835 cu. yd.; gold yield, 238,715 oz. worth $4,300,000. There are 6133 men employed, compared with 8364 in 1913.

MINING IN THE FAR NORTH*

Skagway-White Horse Mining District

By EMIL EDWARD HURJA

The district embodied in this sketch is a vast one made up of smaller districts, tributary to the White Pass railroad, operating from Skagway to White Horse, and for that reason all are treated together. The Rainy Hollow and Porcupine areas are tributary to Haines, a port 12 miles south from Skagway. The Atlin, Wheaton, Conrad, Kluane, and White Horse districts all are served by the railroad from Skagway.

The Rainy Hollow mining district is 50 miles from Haines, and lies within the British Columbia boundary line by ten miles. Martin Conway, Richard Kennedy, and J. W. Burnham own a group of 13½ claims, all of which are crown-granted.

SKAGWAY, ALASKA, TERMINUS OF WHITE PASS ROUTE.

The property is at an altitude of 2000 ft., on the headwaters of the Klehina, a tributary of the Chilcat river. On the Maid of Erin claim, an ore deposit with a width of from 30 to 40 ft. has been stripped on the surface. On the Sonora claim, a 40-ft. adit has been driven in ore. On the Wonderful, a 140-ft. adit comprises the development, and on the Majestic claim is an open cut 40 ft. long. Two men are employed by the owners at present in extending the adits. J. W. Bryant, at present with the Spassky Copper Mines in Siberia, who was to have made an examination of the claims some time ago, has written that he is considering a trip to the district in the near future. Thirty tons of ore from the claims was shipped three years ago to the Tacoma smelter. Net returns were $81.65 per ton. The returns showed 55.67 oz. of silver and 32.17% copper.

In the same district other prospecting is being done. The Three Guardsmen property, owned by A. C. Smith and James Irwin, showing ore of a character similar to the Conway-Kennedy-Burnham group, is being prospected steadily. M. J. O'Connor has two claims on which he is doing the annual assessment work. Timothy Creedon owns one claim on which he is working and Dan Sullivan owns two. A wagon-road built by the Canadian government connects the boundary terminus of the American wagon-road from Haines with the properties in the Rainy Hollow district.

In the Porcupine gold mining district, at least three outfits are at work hydraulicking. The Porcupine Gold Mining Co., of which S. C. Hunter is manager, is operating a plant on Porcupine creek. Between Cahoon and McKinley creeks, the Cahoon Creek Mining Co.'s holdings have been taken over by the Glacier Creek Mining Co., of which Hal G. Knight is manager. Two automobiles are used to haul supplies for the operations. It is expected that the plant will be ready for operation at the beginning of next season. Considerable ditch and pipe-line work has been done.

The Mountain Jewel Mining Co. owns 12 claims in the Salmon River basin, in the Skagway mining district. The prop-

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Development of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29; 'The Koyukuk Mining District,' September 12; 'Operations of the Yukon Gold Company,' October 10. Mr. Hurja in subsequent letters will give full accounts of present conditions in each of the great producing districts of the Far North.—EDITOR.]

erty is 45 miles from Haines. W. J. Bledsoe, chief owner, is preparing a hydraulic plant for operation near the mouth of Nugget creek. Open cuts and shallow shafts have been used to prospect the placer body. Last season's operations produced $375 off rimrock. One $75 nugget was obtained the previous season.

The most recent discovery of gold was made between Rainy Hollow and Porcupine creeks, which caused a small stampede in June. Forty locations were made, a little fine gold was taken out, but only a few prospectors are at work in the diggings at the present time.

Skagway District

Many promising quartz properties are being held for development in the Skagway district. Values so far have been so low that no extensive development has been attempted. W. J. Bledsoe has a group of quartz claims three miles from Skagway above Reid's falls. He is doing the assessment work on them. Assays have shown from 40c. to $60.40 per ton in gold.

During the early days of the Klondike rush, the Skagway valley was plastered with both quartz and placer locations. Very few of them were worked, however, and consequently the mining development of the district has not gone ahead very rapidly. The town of Skagway is situated at the head of Lynn canal. It was the outfitting point for all the stampeders to the Klondike and other interior points. It is a point of call for many steamship lines and the coast terminus of the White Pass & Yukon railroad, which was built during the early days of the rush. The railroad is 111 miles in length and runs to White Horse, the head of steamboat navigation on the Yukon river. During the incumbency of O. L. Dickeson, now the president of the railroad, great strides have been made in the mineral development of the Skagway-White Horse district. Encouragement has been given to miners in the development of their prospects, and in the instance of the Pueblo mine, financial assistance has been given to put the property on a shipping basis and to furnish tonnage for the railroad. The White Pass railroad employs two mining engineers whose duty it is to make reports and examinations of prospects and properties developed, and aid the prospectors in the territory served by the line. They have been of material assistance in the development of the more promising prospects of the district.

Wheaton District

The Wheaton district, tributary to the White Pass railway, lies in Yukon Territory, just north of the British Columbia boundary. The area flanks the mountains of the coast range on their eastern side. The Yukon government has constructed wagon-roads from Robinson, on the White Pass railway, to different parts of the district. Robinson is 78 miles by rail from Skagway. When the influx of gold-seekers to the Klondike was at its greatest in 1897 to 1898, hundreds and thousands of prospectors passed through a corner of the Wheaton district. The first prospecting reported from there was done during the summer of 1893, when Frank Corwin and Thomas Rickman are known to have located a number of claims. They returned to Juneau afterward with some samples of rich ore which assayed over $1200 per ton, but before any steps had been taken to work their discoveries, the men had died. In 1898, W. F. Schnabel is reported to have found veins carrying ore corresponding to that of the two prospectors. In the summer of 1906, the discovery of gold tellurides on Gold hill caused a stampede, and 500 claims were staked within 90 days.

On the west side of Tally-Ho gulch, the Tally-Ho group of 8 claims, owned by Adam Birnie, C. J. Irvine, C. I. Burnside, W. M. Hair, and F. T. McGlashan, is being developed steadily. A quartz vein varying in width from 6 to 36 in. and impregnated with argentiferous galena has been opened up with 350 ft. of drift, two 40-ft. rises, and a 15-ft. cross-cut. Twenty tons of ore shipped recently yielded $54 per ton. Other veins on the claims are being prospected on the surface.

An English syndicate has arranged to send an engineer to look over the Buffalo Hump group of claims, owned by George Stevens and situated along the north end of Mt. Stevens, 16 miles west of Robinson. A vein eight feet wide has been developed with open cuts and shallow shafts. The quartz carries small quantities of galena as well as sylvanite and decomposed tellurides. The Hawkeye group, owned by the 'Tally-Ho' boys, and situated on the Wheaton River slope of Mt. Stevens, has had some surface development done. The largest quartz lens in the district is that on the Acme claim, owned by O. Dickeson. Only assessment work has been done on the McDonald fraction, Silver Queen, and Gopher claims, on the western side of Wheaton mountain.

Becker & Cochran, owners of a group of eight claims on Becker creek, tributary to Wheaton river, 25 miles southwest of Robinson, have incorporated the Wheaton Mining Co. with a capital stock of $90,000. The stock has been taken up by White Horse residents, and development work on the claims

SKAGWAY AND THE BACK COUNTRY.

will be carried on steadily henceforth. The Rip claim has been developed with two adits. The upper, driven on the outcropping, is 387 ft. long. Another adit, 137 ft. below this one, penetrates ore 173 ft. from the portal. One hundred and sixty-five feet of drift has been run on the vein. The vein is five feet wide, with only the 18 in. nearest the hanging wall containing metal to workable extent. Repeated assays show the average value of this ore to be $10.50 per ton in gold, silver, and lead. A basalt dike cuts the quartz vein. On another lode 370 ft. away, but lying parallel to the first, a 110-ft. adit has been driven. On the Wheaton claim, adjacent to the Rip, 40 ft. of adit has been driven on the same vein, with a width of nine feet. The value was less than on the Rip claim. An adit to tap the vein at greater depth has progressed 35 ft. Ore going $50 per ton has been mined from a slide on the Mountain Sheep claim, also one of the group. Only surface work has been done on the other claims. Cabins have been built at the property, looking toward a resumption of work this fall.

Claims in the Gold Hill district have been prospected more or less. Only assessment work is being done on the holdings at present. George Curtis is developing his property on Gold hill. The Gold Reef, Lucky Boy, and Legal Tender claims are the principal locations in this district.

A vein from 14 in. to 3 ft. thick, carrying stibnite, with

BUNKERS AT SKAGWAY.

sphalerite and jamesonite in minor amounts, has been opened by W. J. Fleming on the Carbon Hill group of claims. But little prospecting has been done on the Goodell claims on Carbon hill, or on the Morning and Evening claims on Chieftain hill.

Atlin Distaict

The Atlin Mining district is situated in the northwestern corner of British Columbia between latitudes 59 and 60°. Atlin became known as a productive placer camp in January 1898 because of discoveries made on Pine creek by Miller and McLaren. In 1898 the district produced about $75,000; the following year $800,000 was taken out. The average production since that time has been about $400,000. In 1909 it was $200,000. Estimates of the 1914 production are $450,000, in excess of 1913 by over $100,000. Atlin is reached by a rail journey to Carcross from Skagway and steamer to Taku landing, thence by rail and steamer to Atlin. During the winter a stage runs between Carcross and Atlin. Because of placer activity, interest in quartz mining has not been very lively in the Atlin district. Outside capital is beginning to look toward the district, and engineers of several companies are aircady investigating different properties there.

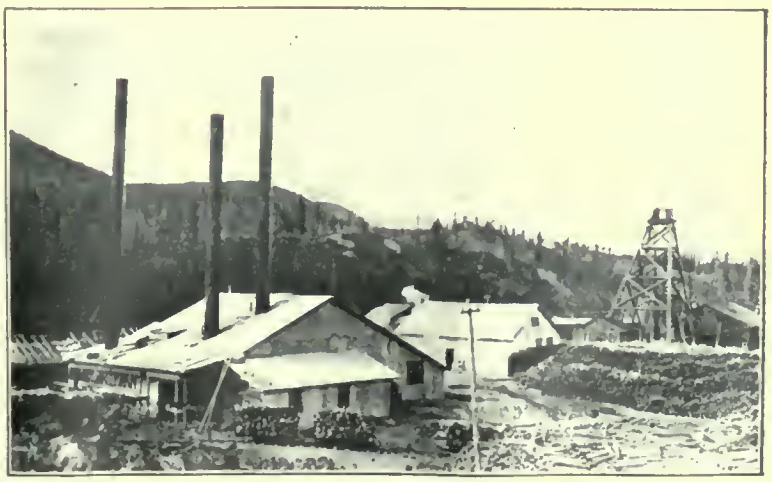
The Columbia Gold Mining Co., of which J. M. Ruffner is manager, is hydraulicking on Pine creek. A crew of 45 men is employed. The Inland Trading Co. is erecting a hydraulic plant on O'Donnell creek, a tributary of Atlin lake. A mile of pipe has been laid. The Company has obtained eight leases on the creek and is assured of ground for its work. Preston & White started to drive this spring on O'Donnell creek. The Pierce outfit is working on Birch creek with a small hydraulic plant. McCluskey brothers, driving on Spruce creek, expect to take out $50,000 this season. T. M. Dalton is having a satisfactory season on Ruby creek, tributary to Surprise lake. Four or five small outfits are at work on Wright creek. On Otter creek, Meithuin & Co., a French syndicate, is erecting a plant with the intention of carrying on hydraulic operations on a big scale next season. Water conditions during the present season have been much better than during the last two years.

Dall & Fleming, owners of the Humper group of quartz claims on Windy arm of Tagish lake, are planning to dispose of their property. H. L. Van Wyck, an engineer representing a Vancouver, B. C., syndicate, recently made an examination of the claims and completed a thorough sampling of the veins. A 5-ft. vein has been uncovered, with an 18-in. pay-shoot carrying gold, silver, and lead. A depth of 130 ft. has been attained. The ore is argentiferous galena. A site for a camp has been graded off at the portal of a proposed adit. The road to the property has been graded and widened. The Conrad property on Windy arm of Tagish lake has a 100-ton reduction plant on it, erected in 1907, but idle for several years. The group comprises three claims, the Montana, Venus, and Big Thing. R. S. Stokes, representing the Canadian Mining & Exploration Co., this season completed an examination of the property. An adit on the Venus claim has a length of 2000 ft. Three stopes have been started. Development work aggregates 10,000 ft. A resumption of work at the property is planned.

The Laverdiere group of quartz claims is the only one on which active work is being done in the Atlin district at present. The property consists of six claims, all of which have been crown-granted. They are situated on the west side of Hobo creek. Two quartz veins have been found and opened on the surface, as well as one contact metamorphic deposit. At one point the ore deposit is 150 ft. thick, and analysis of the ore by mineralogists of the Canadian Geological Survey shows magnetite, hematite, chalcopyrite, and malachite. Tunnel work in excess of 400 ft. has been done on the different claims. A mining engineer from Dawson left White Horse for Atlin, July 25, to make an examination of the claims.

A number of copper locations have been made recently near Carmacks. On the Bonanza claim, owned by C. P. Mack, an open cut has been made into the orebody. The hill has an iron capping impregnated with chalcopyrite. Two hundred feet from the top, an adit has been driven. The vein outcrops along the top of the hill for a distance of 900 ft. Ore has been found on the adjoining Hazel May claim at a depth of 300 ft. greater than the Bonanza. On Merritt creek a number of locations have been made. Three hundred ten feet of adit has been driven on one group situated two miles from Lewes river. Different leads are being developed, varying in width from two to ten feet. A lode eight feet wide, between granite and diorite, said to contain 10% copper ore, is being opened a mile from Lewes river.

The Kluane district, west of White Horse, is getting more attention now than before, because of the number of men who went through en route to the Chisana field. Small hydraulic plants are at work in many parts of the district. That quartz prospecting is being taken up is reported by the territorial assayer, W. C. Sime, of White Horse. E. G. Lewis, an engineer in the employ of the Atlas Mining Co., last fall prospected the lower part of Gladstone creek, 3½ miles from



ATLAS MINE; BOILER HOUSE AND SHAFT.

its outlet to Kluane lake, with a Keystone drill, with a view to determining availability for dredging purposes.

White Horse, Yukon Territory, took shape around the settlement at the foot of White Horse rapids, a treacherous stretch of water through which hundreds of stampeding miners went with their boats during the years 1896 to 1899. It is the terminus of the White Pass & Yukon railroad, is the outfitting centre of a big area of country, and the head of steamboat navigation on the Yukon waterways. It has modern hotels, a mounted police barracks, a weekly newspaper, and numerous stores. Many mines are adjacent to the town.

Assessment work is being done on the Arctic Chief claim, owned by the Arctic Chief Mining Co., seven miles west of White Horse.

The Pueblo Mine

The Pueblo mine is a constant shipper now. It is situated seven miles from White Horse by wagon-road and is operated by the Atlas Mining Co. under a 20-year lease. Five claims making up the group were staked in 1900. The present Company took over the operation of the mine in 1912. The development work of the Company has been centred on the contact deposit on the Pueblo and Pueblo No. 3 claims. New work on the property consists of development on the 400-ft. level, where, up to July 1, 622 ft. of cross-cut had been driven. Present development work on the lower level now aggregates about 800 ft. Ore is being mined from one stope on the 400-ft. level. Mining is done from a vertical shaft 450 ft. deep. For the lower 300 ft. the shaft is three-compartment; the rest of the distance to the surface it is two-compartment. Mining is being carried on from the 200-ft. level. Drifts on the 200-ft. level aggregate 1600 ft. The fill system of mining is followed entirely. Timbering with square sets is necessary because of the unstable character of the walls. Native timber, of which a good supply is available, is used. The ore mined is a hematite carrying copper and silver. The copper content varies from 3½ to 6%. Four bodies of ore have been found on the 200-ft. level and are mined from what are known as the east, northeast, west, and northwest stopes. The northwest body has been found recently on the 400-ft. level. The carbonates on the 200-ft. level are giving way on the lower level to sulphides. Native copper, chalcopyrite, cuprite, and specular hematite form the chief minerals. The ore is very desirable for fluxing purposes. Shipments are made by railroad to Skagway, an 11-mile spur connecting with the White Pass railway, and from there to the Tacoma smelter by steamship. In 1912 shipments aggregated 31,538 tons; in 1913, 36,663 tons; and up to July 1, 1914, 7399 tons. Shipments are aggregating 250 tons per day at present. Present plans provide for sinking the shaft to a depth of 650 ft., the work to start this fall. A rise from the 400-ft. level to the surface has been started, to provide an emergency outlet from the lower level. An incline shaft has been completed from the 200-ft. level to the surface. Diamond-drill work is being done in an effort to outline the dimensions of the orebodies. During 1913, 28 holes were drilled an aggregate length of 3796 feet.

Mine equipment consists of a 16 by 9 by 18 Cameron station pump and six sinking pumps, a No. 5, a No. 9B, two No. 9, and two No. 7. Water is discharged from the mine at the rate of 400 gal. per minute. Three 150-hp. boilers using wood as fuel supply power for an Ingersoll-Rand straight-line Class AA2 compressor and a Franklin compressor, as well as a Lidgerwood 12¼ by 15 hoist. A Sturtevant mining set supplies the mine workings and buildings with electric light. A Cochran feed-water heater has been replaced by a 60-hp. locomotive type boiler, by means of which water is heated with exhaust steam. An ample supply of hot water for all uses is thus obtained. A complete machine-shop is maintained at the property. Equipment includes lathes, drill press, and a Leyner drill sharpener. During the summer, 200 men are employed, including woodcutters and teamsters. Mess and bunkhouses are well and comfortably furnished.

Prospect work is being carried on by the Company on the War Eagle and Leroy claims, situated a mile north of the Pueblo property. The claims are under bond to the Atlas Mining Co. A hand drill is in use on the War Eagle. If developments at the property justify placing it on a shipping basis, the spur to the Pueblo mine can be extended easily to the property.

The Anaconda claim, situated four miles from White Horse and owned by W. A. Puckett and associates, was originally located September 28, 1898. Its first development was in the hands of W. S. Thomas, who represented James Guffey, of Pittsburgh, Pennsylvania. Since 1907 the claims have been in the hands of Mr. Puckett, who is doing a small amount of development each year. On the Anaconda two parallel contact deposits of bornite, one from 12 to 14 ft. wide and the other 4 ft. wide, both 55 ft. apart, are being opened. Shallow shafts and open cuts comprise present development. The adjoining Rabbit Foot claim has a 20-ft. shaft on a deposit similar to that on the Anaconda. Several hundred tons of ore is on the dump awaiting shipment. S. Tanner, said to represent English capital, has asked for a bond on the claims. J. R. Alguire is prospecting the Sandon claim, 400 ft. north of the Pueblo. The ore deposit is said to be an extension of the Pueblo deposit.

The Livingston Creek district, in the Big Salmon watershed, is the scene of considerable activity in placer mining. Some quartz prospecting has been done, but because of the inaccessibility of the area, development has been slow. On the left limit of Livingston creek, James Geary is operating one giant on the claims of the A. C. company. D. G. Snure is driving into the hillside a short distance below to tap a bench pay-streak. A. M. Wallick, on 1 Above Discovery, has discovered some rich dirt in frozen ground. He is using points to thaw the ground. H. Berry is drtving an adit into the hillside gravels, trying to find another channel. It is in a distance of 350 ft. On Lake creek, LeRoy Churchill is hydraulicking with one giant. A. Officer is driving in thawed ground and is reported to be working good pay.

J. E. Peters worked until the middle of June on Summit creek, but was forced to suspend operations because of a shortage of water for sluicing. He has started a sawmill and is cutting lumber for a flume 6500 ft. long which he hopes will eliminate damage from droughts. He already owns four claims and has options on more, so that he will have ample ground for his proposed work. Peters plans to start hydraulicking on the upper end of Discovery. George Bruce is mining pay by the open-cut method below Peters' claim. William Clethero is hydraudicking with a single giant on Little Violet creek. L. Keyzer is working a small hydraulic plant on Cottoneva creek. An automatic dam controls the water-supply. A Pelton water wheel is used to hoist the boulders. One nugget, worth $215, was found during the present season.

On Quiet lake, at the head of the Big Salmon river, Alexander Brown has found gold on Brown creek, tributary to the lake. He drove up on the rim on one side and took out $156. Upon petitioning the government for a road, work was started at once. He expects to do more work next winter on the find. Twelve men are prospecting in the district.

W. Cameron, working at the head of Sheehan's gulch, a tributary of Livingston creek at 1 Above Discovery, has crosscut a quartz lode with a width of 75 feet.

The mineral resources of Yukon Territory, northern British Columbia, and that part of the Skagway recording district lying adjacent to British Columbia are but scratched. Encouragement has been given in every manner to prospectors and miners. The Yukon government is particularly willing and anxious to aid prospectors by building trails and wagon-roads where they will be beneficial in developing the mineral resources of the country.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

WAIHI, NEW ZEALAND

GOLD AND SILVER OUTPUT OF THE DOMINION.—THE WAIHI FIELD GEOLOGICALLY DISCUSSED.—FURTHER DEVELOPMENT SCHEMES.—THE THAMES DISTRICT.—BLACKWATER, PROGRESS, AND WEALTH OF NATIONS MINES.

The gold output of New Zealand for July 1914, amounted to 27,150 oz., valued at £110,828, compared with 40,103 oz., valued at £154,319, for July last year. The silver output was 53,017 oz., valued at £5313, against 107,909 oz., valued at £11,984. The gold output for August amounted to 3045 oz., valued at £12,876, against 41,442 oz., valued at £156,348, a year ago. The silver output was 32,410 oz., valued at £3240, against 68,135 oz., valued at £7446. The heavy falling off for August was due to the decrease in exports due to the war risk of shipping bullion to England.

A languishing industry and a lack of capital for new enterprises seems to be affecting the Waihi district. The parent mine, the Waihi, is practically living on its ore reserves. For the year 1913 the ore developed was 197,222 tons, against a mine output for the same period of 183,124 tons. At the end of August, work at No. 11 level was delayed for some time on account of an accident and disablement of the 'B' pump. On the bottom levels of the mine, gold and silver content of the lodes are not consistent, and shoots are not extensive.

The Waihi Grand Junction Co., whose property adjoins the Waihi, is producing steadily. Recent developments on the 1082-ft. level (No. 6) have been most encouraging, disclosing a long run of good-grade ore on the Empire lode. As forecasted by J. M. Bell in his geological report to the New Zealand government, this vein has now become the main one on the field, the great Martha lode being of little account as an ore producer in either the Waihi or Junction mines. At 786 ft. east from the main cross-cut in the Junction mine on No. 6 level, the Empire is cut off by a fault, and Mr. Bell held small hopes of profitable ore being opened up by development beyond this faulted area. In spite of this, the management drove through the broken country beyond the fault, and at 200 ft. came again on the Empire lode, which proved to be 20 to 30 ft. wide, with several feet of milling ore on both walls. The drift is now, August 28, 1220 ft., from the main cross-cut, and is going ahead in sulphide ore on the south wall, the ore broken going to the mill for treatment. At 1180 ft. a cross-cut was driven through the vein, proving it to be 40 ft. wide, of which 5 ft. is worth $8.16 per ton, the remainder being of low grade. At 1100 ft. a cross-cut proved the vein to be 28 ft. wide, with 7 ft. on the hanging-wall side worth $7.28 per ton, and 30 in. on the foot-wall side worth $5.76 per ton, and the balance low grade. The reef is solid and well defined, and as the workings are 1700 ft. from the boundary on the strike of the vein, the possibilities are great.

These developments in the eastern portion of the Junction property have considerably enhanced the prospects of the adjacent property owned by a Wellington company, and known as the Waihi Gigantic Reef Consolidation, Ltd. (the old Waihi Consolidated and other claims). This latter concern, in spite of the exaggerated pretensions of its friends is a genuine prospecting undertaking. If the Empire or other lodes are found eventually to continue through into this property, they must be deep seated, and, in order to carry out any comprehensive scheme of exploration, it is necessary for a company to be well capitalized. Capital has not been freely forthcoming for this new venture, chiefly on account of the field being under a cloud by reason of the adverse character of the report on the field by Mr. Bell.

According to his theory, the 'productive' area is restricted to a supposed 'intrusive' mass of dacite which is encircled by an 'inferior' or bedded dacite. The area of the dacitic intrusion at the 1000-ft. level in the Waihi mine is given as about 1320 by 3300 ft., and the fault already referred to in the drift on the Empire vein in the Junction mine is supposed to mark the approximate boundary between the 'intrusive' and 'bedded'

dacites in this part of the mine. Although Mr. Bell expresses his opinions in most guarded language, the only inference which can be drawn from his statements is that it is not of much use prospecting in the bedded dacite. According to utterances of W. F. Grace, general manager for the Waihi Grand Junction company, when interviewed by a *Herald* representative in Auckland in August, this theory has now been exploded so far as the eastern part of the field is concerned, and this is obviously so when it is stated that milling ore has been developed in bedded dacite 500 ft. beyond the boundary of the supposed intrusion. Furthermore, it would seem that some structural differences between the two classes of dacites should exist, and possibly be detected in hand specimens or rock sections; but Mr. Bell does not allude to any such differences in

his report. Possibly the strongest evidence against the theory is supplied by the discovery in the Waihi mine of a carbonaceous seam, where the rock was supposed to have been intrusive. Such seams are specially mentioned in the geological report, as indicating the bedded nature of certain masses of dacitic rock. A petition is now in circulation in Waihi with the object of inducing the government to revise the geological report on account of this new evidence. Needless to say, the prime movers in this are those interested in the Consolidation company, whose prospects would be very much improved if Mr. Bell's theory were definitely disproved. The present position is certainly very unsatisfactory, and the local press has been very outspoken on the matter.

August bullion return of the Waihi mine was £25,466 from 14,538 tons of ore; and Grand Junction 10,200 tons yielding £20,100. The working cost of the latter was $4.76 per ton.

J. W. Walker, well known as one of the original promoters of the district, is trying to get a concession from the government for ground on the eastern side of Waihi. His idea is to drive a cross-cut from the ocean beach, six miles east, to the Junction mine. It is thought that as the shoots in this mine have a fairly sharp pitch east, the drift will be above any good ore that may exist.

The Talisman at Karangahake relies on its Bonanza shoot to keep up its $22 average, but the end of the shoot is not in sight.

The Thames district of the North Island, 36 miles north of Waihi, is very dull at present, from a mining standpoint, in fact, if it were not for the fishing and dairying industries it would be a deserted village. Deep-level development, that is, testing the whole field at a depth of 1000 ft. from the Queen of Beauty pump shaft, which is practically at sea-level, is not very promising. The main cross-cut at that depth was driven to the Moanataiari fault, but work was stopped until the water and gas were drained. During this time the Waiotahi shaft was sunk to connect with this cross-cut, and a junction was made late in July. By using this shaft as an upcast to the Queen of Beauty shaft (about a half-mile distant) aided by a Sirocco fan, the cross-cut is now well ventilated, and the May Queen company, whose mine adjoins the Queen of Beauty, has started to open the Exchange lode. This is the only orebody cut during 3000 ft. of driving that showed any promise and it is too small to forecast any great help for the district. The Waiotahi, which four years ago yielded a bonanza of $2,400,000, will continue to develop the Cambria lode and foot-wall leader. An assessment will be made to carry out this work. The Tararu end of the field, about three miles from those mines mentioned, has been producing almost the total bullion output for the past year or so. The Sylvia is yielding about $5000 per month, and keeping out of debt. Sinking is to be done. The Watchman mine was expected to average $11.14 per ton, but the stamp-mill gives only $6.

In the *Press* of September 19 were given the annual reports of the Blackwater, Progress, and Wealth of Nations mines, which are at Reefton in the South Island. A report for the second quarter of 1914 shows the following results:

	Blackwater.	Progress.	Wealth of Nations.
Development, feet	1,045	846	582
Width of lode opened, inches	17	49.3	43.3
Assay of lode opened, per ton	$6.96	$5.03	$4.15
Ore treated, tons	12,731	8,441	6,750
Average yield, per ton	$ 8.96	$ 5.97	$ 7.34
Total cost, per ton	5.04	4.90	4.56
Working profit	49,000	9,700	19,500

As the cyanide manufacturing company of Glasgow is able to supply Africa, it is likely that it will be able to keep New Zealand mines going. Large stocks are usually carried. No zinc dust is used, but zinc sheets are imported. Practically all the silver produced in the Dominion is from the Waihi-Karangahake district.

JOHANNESBURG, TRANSVAAL

DEVELOPMENT OF THE FAR EASTERN RAND.—GOLD OUTPUT AND PRETORIA MINT.

Everything seems to point to the far east Rand beyond Boksburg, for at least some distance beyond Springs, contributing a fair proportion of the gold output of the Rand in the immediate future. It is true that the profitable proportion of the reef area cannot compare with that of the Central Rand, say from the Nourse to the Langlaagte mines, but the far eastern portion has already shown itself to be more profitable than the far western Rand. The way in which the Van Ryn Deep, Modder Deep, Brakpan, Government Areas, Geduld, and Springs have opened, has done much to rehabilitate the far eastern Rand in the good opinion of investors, as until these properties were developed the area was not in much favor. The broken country east of the town of Boksburg was much to blame, and even when the Main Reef series took a decided turn north toward Kleinfontein, it was still of low value. The fact that it took at least 20 years of almost continuous prospecting on Reitfontein, now the Apex Mines, to find a satisfactory area of reef, did not mend matters, while the results achieved at the Van Dyk and Rand Collieries seemed to add much to the doubtful value of this new field.

The August gold output of the Transvaal was 711,918 oz. valued at £3,024,037, against 732,485 oz. and £3,111,398 in July. There was an increase of 1825 boys employed at the gold mines; but a reduction of 11,603 in the total employed at gold, coal, and diamond mines, due to closing the latter. The export of raw gold has ceased until trade routes are safe, and the mint at Pretoria has been overhauled with a view to coining money. This institution has not worked since shortly after the Boer war.

WESTERN AUSTRALIA

DIVIDENDS PAID.—REPORTS OF PERSEVERANCE AND OROYA LINKS COMPANIES.—AUGUST GOLD RETURNS.

Dividends paid by mining companies of this state in June and July amounted to £99,052 and £55,428 respectively. The total to date from all mines is £24,312,230.

Eleven mines at Kalgoorlie used 32,013,900 gal. of water in June in the treatment of 152,885 tons of ore.

The second quarterly report of the Great Boulder Perseverance company shows that development totaled 1353 ft., and the stock of broken ore in stopes is 222,808 tons. Out of 886 ft. driven on lodes, only 267 ft. was in ore over $4.80 per ton. Work at 2200 ft. failed to show any general improvement, although the lode is promising. The 'D' lode continues to produce fair ore. The mill treated 62,889 tons of ore yielding $5.18 at a cost of $4.12 per ton.

The second quarterly report of the Oroya Links company shows that development totaled 1015 ft. Work at 900 ft. in the Eclipse mine has shown considerable improvement, ore worth from $5.28 to $7.92 per ton being opened for a width of 79 in. The 50-stamp mill and cyanide plant treated 36,400 tons averaging $5.30 at a cost of $3.92 per ton.

In the *Monthly Journal* of the Chamber of Mines for June the geology of the Oroya Black Range mine is discussed by R. C. Wilson. In the July issue is a paper on the repair of the crank-shaft of a gas engine, and which will appear in another issue of the *Press*.

August returns were as follows:

Mine.	Tons.	Value.	Profit.
Bullfinch	6,463	$ 52,000	$ 17,000
Golden Horse-Shoe	25,056	170,000	16,000
Great Boulder Perseverance	....	.....	21,000
Great Boulder Proprietary	17,161	235,000	135,000
Ivanhoe	19,700	152,000	.....
Sons of Gwalia	13,270	97,000	24,000

NEW YORK

THE EMBARGO ON COPPER TO GERMANY STILL UNDER DISCUSSION.—OLD DOMINION AND WOLVERINE OUTPUTS.—RIO TINTO DIVIDENDS.—GRANBY CONSOLIDATED REPORT.

Copper producers were worried last week by the diversion of shipments of copper consigned to Holland by the British authorities, on the ground that such shipments would inevitably fall into the hands of the Germans. The British paid for this copper, but they did not pay the price the producers expected to get, and they were naturally loath to see their regular sales to England cut down by the capture of conditional contraband. The principal producers and sellers had repeated conferences last week, and meanwhile it was announced that Mr. W. J. Bryan and Sir Cecil Spring-Rice, the British Ambassador, had agreed to meet the situation by endeavoring to obtain from the government of Holland official assurance that that country would only import copper in quantities sufficient for domestic consumption. As Holland is a large consumer of copper, it seems quite probable that such an arrangement can be made. It is evident, though, that copper production in this country will have to be further curtailed. The German market, the largest one, has been completely cut off, and though England and France have so far taken large quantities of copper, it is only reasonable to expect that the emergency requirements of those countries will soon be filled, after which their takings can be expected to be less than normal. This situation can best be met by the shutting down of those companies which are unable to make any profit at the present price of the metal. By keeping going, they merely increase stocks, thereby depressing the price, and when normal times return the price of copper will have just that much higher to climb before they can make profits again. In other words, by operating for a month longer now, it is quite probable that their eventual reopening will be delayed two months, so that they will be losers rather than gainers. Of course, the hope of these companies is that they will be able to tide over the crisis without having to shut down at all, but from present indications that is a vain hope.

The Old Dominion made an output of 2,121,000 lb. in September, and Charles S. Smith, the president of the Company, reports that conditions at the property are entirely satisfactory, costs not having materially increased despite the one-third reduction in the output. A 10% reduction has been made in the wage scale, and the ore now being mined is of better than average grade.——The Wolverine reports an output of 401 tons of mineral in September, which is more than the average of preceding months.——The Rio Tinto company, of Spain, has passed the dividend on its ordinary, but paid on its preferred stock, and the Miami has deferred action on its dividend.——The copper mines in Alaska have cut output to half of normal.

The Granby Consolidated Mining, Smelting & Power Co. has issued its report for the year ended June 30, 1914. The production and income account compare as follows:

	1914.	1913.
Copper, pounds	23,320,097	22,688,611
Silver, ounces	435,275	324,336
Gold, ounces	43,882	47,266
Gross income	$4,504,766	$4,782,691
Operating expenses, etc.	3,882,695	3,568,092
Net profits	622,071	1,214,599
Depreciation, etc.	182,519	81,495
Dividends	899,901	449,955
Deficit	460,349	*683,119
Previous surplus	3,199,270	2,516,122
Total surplus	2,738,922	3,199,271

*Surplus.

GRANBY SMELTER AT GRAND FORKS, BRITISH COLUMBIA. TEMPORARILY SHUT DOWN ON ACCOUNT OF THE COPPER MARKET.

Copper for 1914 sold at an average of 14.58c. per pound; silver, 57.74c. per ounce; and gold at $20 per ounce. This compares with 16.04c., 61.18c., and $20, respectively, in 1913. The superintendent of mines, J. B. Smith, reports the following quantities of ore in sight at present: Phoenix, 4,691,531 tons; Anyox, 18,153,000; Midas, 116,344; Mamie, 135,200; and It-Dean, 5000; a total of 23,101,075 tons. Treatment costs increased to $2.73 from $2.65 per ton, owing to the new plant being included. The cost per pound of copper was 11.5c. In the development of the Anyox properties, the Company has expended about $3,000,000, and the normal production from them is expected to average 2,400,000 lb. per month.

WASHINGTON, D. C.

'CONSERVATION' BILLS FOR NEXT SESSION.—THE ALASKA COAL LEASING BILL.

The President is determined to see through the next short session of Congress the so-called conservation bills, which include the 'leasing' bill, which is feared by many in the mining industry as an entering wedge whereby the so-called leasing system will be applied to what remains of the public domain, inclusive of mining lands. To this, mining men are greatly opposed, and possibly on account of the shortness of the session, senators from the mining states may be able to frustrate the determination of the President to obtain this legislation from Congress. As it is, oil lands and coal lands are affected.

Quite to the point on this score is the enactment by this session of Congress of the Alaskan coal leasing bill. One measure was passed by the House, but the Senate, when it got the bill, eliminated all after the enacting clause and substituted a bill after its own ideas. Of course, the bill went to a conference between the two Houses, and the committee has reported a compromise between the two measures, and this is to become a law. It is declared by the House conferees, Congressmen Ferris, Graham, and Lenroot, that the conference has brought the Senate and the House bills into harmony by certain modifications, the provisions of which embody the essential features of both bills. The amended bill, as agreed to in conference, provides for the appropriation of $100,000 to make the surveys necessary to proceed intelligently with the leasing. It was ascertained that the current appropriations for the surveys in the West were made prior to the passage of the bill, and did not contemplate any surveying work in Alaska.

Though the conference committee on the Alaskan leasing bill was quite content with its work, the Senate did not like its report, and debated it for a day, and at the close on Saturday, October 10, led by Senator Lane of Oregon,

it sent the bill back to conference on the ground that the conferees had inserted new matter in the bill not considered in either House of Congress. This rule has not been invoked in a long time, and Senator Myers of Montana protested vigorously. He said as a result the bill probably cannot be enacted at this session. This may or may not be, but in the end the bill will be passed, and it is expected not to differ much from the lines laid out in the conference report.

BRISBANE, QUEENSLAND

Mineral Production and Condition of the Industry.—Mt. Morgan Affairs.—The Gympie Goldfield.

Mineral production of the state, other than gold, coal, or precious stones, in the second quarter of 1914, was valued at £460,274, against £503,649 in the same period of 1913. The gold output for the first seven months of 1914 was 135,578 oz., a decrease of 29,853 oz. for that term of last year.

Speaking generally with regard to Queensland mining, it seems to be suffering from lack of capital. The country is so prosperous that surplus capital has been devoted to a greater extent than heretofore to the staple industries, to the detriment of the mining industry.

The annual meeting of the Mt. Morgan Gold Mining Co. was held at Rockhampton on July 17. The chairman of directors stated that the new plant has been started, to the extent that two of the new furnaces are in commission and are each easily treating 350 tons of Mt. Morgan ore daily. The concentrator has been started, and is now running at about half capacity. It is hoped soon to bring the plant up to full capacity. Basic-lined converters were recently installed to take the place of the silicious-lined converters. These newly-lined vessels have now been running a few weeks, and have proved to be a great success. It is too early as yet to get anything like reliable figures as to the work being done at the new plant; but from what can be seen so far, it is felt that the results, when everything is settled down to smooth working, will be found to be quite as good and probably better than anticipated. The general manager, B. Magnus, stated that the high-grade ore is all for the furnaces, and the medium-grade and unpublished reserves were for the concentrator. The estimated monthly copper output is about 800 tons.

Mining in Gympie is at a low ebb. In July the output from eight mines was 10,241 tons of ore yielding 3577 fine ounces gold. The mines mostly are working from hand to mouth. There are no ore reserves, and nothing was put aside in the fat years to tide the companies over the lean years. The result is there is no money available for prospecting work. The Scottish Gympie is the only mine which makes any pretension to work continuously, and even in this case the net result of monthly operations is very often on the wrong side of the account. The July return was 5000 tons of ore worth $20,200. The Scottish Gympie people are the pioneers of fine grinding and cyaniding, which has only been introduced in this field to a limited extent. Save this Company's plant, the few cyanide plants which exist are of a very primitive character, and are only used in connection with small heaps of old tailing. No doubt the limited application of the cyanide process is due to the graphitic nature of the ore which in some way causes difficulty in extraction, but there can be no question that large sums in value of gold which has found its way into the creek might have been saved by finer grinding of the ore, and the consequent improved extraction on the plates. In order to get a fair output per stamp, a 15-mesh screen is the standard size used, and this has resulted in losses which might have been avoided. The country around Gympie is becoming more settled every year, and as a matter of fact the place is now very much more dependent on its agricultural interests than upon the mining industry.

PLATTEVILLE, WISCONSIN

Condition of the Zinc, Lead, and Pyrite Markets of this Field in September.—District Production and Buyers.

A review of operations in the zinc-lead districts of the Platteville field for September reveals extremes in both prices and production. The high figures reached in the last two weeks of August, under the spur of a sharp but spasmodic foreign demand for spelter, was carried over into September, and for the first 10 days blende ores commanded a price in advance of $50 per ton for 60% grades, stimulating production at all points and establishing a new record for maximum production, as usually reported for this area. But this foreign demand vanished into thin air, and prices steadily receded to the levels obtaining during the long period of depression existing prior to the increases inspired by foreign buying. Spelter closed in the last days of the month at $5 per cwt., East St. Louis quotations, but the well informed insinuated that large consumers of spelter could drive even better bargains, and a feeling of discouragement possessed operators in the field in general, production going back in sympathy with the downward movement of prices for both ore and metal, the month finally winding up dull and featureless in all branches of the industry. The base price reported for blende ores had gone back entirely, quotations ruling unsteadily at $39 to $41 per ton for standard commercial zinc ore. No effort had been made to work off a big surplus that was stored in bins, and the first of October found 6000 tons of all grades in bin in excess of the regular deliveries. Prospecting and development work received a serious setback, and the optimistic tone was supplanted by a feeling of gloom.

The lead markets were dull all the month, pigs declining to a point under $3.50 per 100 lb., East St. Louis, with light business reported. Lead ore was in poor demand, and shipments were almost negligible. Production has fallen away almost entirely, except where secured as by-product, and very little surplus is held in this ore.

Production of pyrite, usually running as high as 2500 tons per month, took a decided slump on account of off prices. In the hope that competition might bring substantial benefits, the leading producers diverted their offerings to new buying interests, but this had little or no effect, and the shipments for the entire month were exceedingly light.

The following deliveries of ore were reported for the month, by districts:

District.	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	5,890,000	.....	757,000
Cuba City	4,448,000	.....	.....
Galena	4,188,000	120,000	.....
Hazel Green	2,812,000	.....	.....
Livingston	2,574,000	.....	.....
Shullsburg	2,536,000	60,000	.....
Linden	1,496,000	61,000	.....
Mifflin	966,000	103,000	.....
Highland	812,000	.....	.....
Platteville	752,000	.....	.....
Montfort	260,000	.....	90,000
Mineral Point	210,000	.....	.....
Totals	26,944,000	344,000	847,000

Sales were distributed among the following smelter concerns: Mineral Point Zinc Works, 5800 tons; National Separating Works, 1857; Grasselli Chemical Co., 1282; Campbell Separating Works, Cuba, 1171; Matthiesen & Hegeler Zinc Co., 931; Illinois Zinc Co., 821; Empire Roasters, 659; Linden Zinc Co., 494; American Zinc Co., 230; and American Metals Co., 227 tons. Extensive surveys were made during the month in the Highland district by the New Jersey Zinc Company.

THE MINING SUMMARY

The news of the week : by our special correspondents and reflected by the local press.

ALASKA

Chisana

The season is over in this district, and about 200 out of 400 will remain through the winter. Miners who recently reached Dawson from Chisana estimate the season's output at between $210,000 and $215,000. Most of this went out through McCarthy and Cordova. Hamshaw and associates recovered about $130,000. He will stay and drill ground this winter. F. Best was the most successful individual miner, followed by C. Whitham, Range and Stone, and A. Taylor. Mail is occasionally sent in by way of McCarthy.

A discovery of copper-gold-silver ore has been made at the head of the Snag river by R. A. Lindsay, F. Farnham, and J. O'Hara, according to W. Steinberger, who recently returned to Dawson from Chisana. The district is 25 miles northeast of the latter place, and in line with the Nabesna copper belt. Sixteen claims have been staked, and include the best ground.

Ketchikan

(Special Correspondence.)—The effect of the European war is being felt in this community as a number of ventures being financed with European capital have been obliged to suspend operations.——Both the Alaska Venture Syndicate and the exploratory work of the Granby company are in this class. The Jumbo and Sulzer are also closed temporarily and Charles Sulzer is campaigning for the position of territorial senator. Rush & Brown are working, the Prineeton M. & M. Co. is operating at Dolomi, and the Sea Level mine is being unwatered for examination, but in general things are much quieter here than earlier in the season.

Ketchikan, October 8.

Valdez

The president of the Valdez Creek Power & Mines Co., George W. Sias, recently arrived at Cordova, the trip from the mines taking five days. He stated that a new ditch, 11¼ miles long, 8 ft. wide at the bottom, 15 ft. at the top, and 4 ft. deep, to carry 3500 miners inches per 24 hours, had been constructed; also a penstock, flume, and one mile of pipe. The clean-up will be a good one, although sluicing was only done for a few weeks. A Keystone drill is to be sent in.

ARIZONA

Cochise County

The first annual report of the safety inspector, Wallace McKeehan, of the Copper Queen company, has been issued. The department was organized in the summer of 1913. A rescue station, in which all necessary apparatus is kept, was erected. The inspector visited various coal and iron mining districts of the country, also the U. S. Steel Corporation's plants, to study safety systems in use, and a great deal of valuable information was collected from other sources. In the meantime, notices were posted at the Copper Queen mines and plants relative to the movement and to interest the men in safety during working hours. Cooperation with the Company was asked. During the year of organized effort against accidents, there were 4 fatal, 4 serious, and 2271 minor or slight accidents, a total of 2279. As no previous records were kept, a comparison is difficult, but there appears to be a decrease in fatal injuries of about 55%, serious ones 40%, and a large reduction in minor troubles. This is no doubt due to 'Safety First.' There was an average of 190 accidents per month. Of the total number, 33 might have been prevented by additional precautions by the Company, 1572 by the injured employees, and 134 by fellow employees. There were 233 infractions of the Company's rules, and 501 accidents were unavoidable. In the mines 160 men were hurt at chutes, 96 by ordinary falls, 187 by mine cars, 298 while using tools, and 152 suffered from strains and sprains. From falls of ground 524 accidents occurred, 4 of these being fatal and 32 serious. In 669 cases, or 46%, there was no loss of time during records of 9 months. Twenty-three per cent of the men received first-aid treatment before leaving their place of employment. Lay-offs from strains and sprains are on the

MAP OF ARIZONA, ALSO PART OF MEXICO WHERE FIGHTING IS UNDER WAY.

increase, and as it is impossible to say how badly a man feels from these causes, it is suspected that some men are not sincere about it. Mine-rescue work is conducted on the lines proposed by the U. S. Bureau of Mines, and training and equipment is in charge of J. B. Frank. The Draeger oxygen apparatus, of 1913 pattern, is kept in the best condition. The rescue corps has been called upon for work at El Cumbre tunnel, in Mexico, where 51 passengers were burned to death; and at the mines of the Cananea Consolidated Copper Co., Cananea, Sonora, Mexico, where 16 Copper Queen men were constantly employed fighting the fires for seven days, a part of the men remaining for 18 days. At both of these fires the work done by the men was as effective as could be expected under the conditions. There was only one fire in the Copper Queen mines during the year, this being in division No. 2 and being put out after about 10 hours work. Everybody is proud of this corps. Generally speaking, the new safety department is a decided success.

Gila County

A proposal has been on foot for some time to split this county, and form a new one from part of it, with the name of Miami county. This is to be voted on at the elections on November 3. While taking only 285 square miles, or one-sixteenth of Gila county, the new county would absorb about half of the revenue.

CALIFORNIA

Butte County

The Pacific Dredging Co., well known in Oroville, has started a new dredge in the Butte Creek district, six miles from Chico.——The Supreme Court of the state has confirmed the decision of the Superior Court of the county, which rendered a judgment of $20,000 for the wife of W. Crabbe against the Mammoth Channel Gold Mining Co., in whose mine, near Magalia, he was killed.

Shasta County

The first run of the electric smelter at Heroult on manganese ore produced four tons of ferro-manganese.——The first clean-up from the Mad Ox mill has been sent to Redding. The mine is opening satisfactorily.——Unwatering the Midas mine at Harrison gulch, which was flooded on account of a fire last spring, has reached 12 ft. below the 500-ft. level. Electric pumps at 600 ft. are still 'drowned.' The cyanide plant has been overhauled.

Siskiyou County

At the Forks of Salmon company's gravel claims preparations are under way for a busy winter at hydraulicking. The water supply is still good for work on the Salmon river.——The Michigan company is also preparing its Red Hill placers on the same river. L. E. Taggett is superintendent.——The Wike claims are developing well.

Tuolumne County

(Special Correspondence.)—A shoot of ore, which assays from $20 to $60 per ton, has been uncovered in the Golden Slipper mine, in the Knights Creek district, by A. C. Johnson. ——At the DeWerdt mine, near Columbia, recently bonded to Clark Sullivan, of Berkeley, a cross-cut is being driven from the shaft to cut the vein. Some good ore was taken out of the property by former operators.——One hundred tons of ore from the property of A. E. Caldwell, on Five-Mile creek, yielded $1160. A few small pockets, aggregating several hundred dollars, were taken out recently, in addition to the above sum mentioned.——The William Scattergood ranch, on Bald mountain, has been bonded to W. F. King, of Sonora, who intends to prospect it for gold. The price is $4750, payable within three years.——R. W. Steckel and associates, who are leasing a portion of the Jumper mine, at Stent, have uncovered rich ore, stringers of gold running through the rock in all directions. Chunks of the ore chiseled out during the past week were on exhibition here. The ore is of the same character as that which made the mine famous a number of years ago, when more than $6,000,000 was extracted.——The F. J. & M. Mines Co. has secured a bond on the Wise mine, situated near Tuttletown. An air-compressor has been installed.

Sonora, October 9.

COLORADO

San Juan County

A new mining district, known as Cow Creek, is being prospected, and a number of well known men from Ouray have inspected the place. The ores contain silver, gold, lead, and copper.

Summit County

Breckenridge is extremely active and prosperous. The last gold shipment of the Tonopah Placers dredges was valued at $41,000. No. 1 boat is cutting through ground used by a branch of the Colorado & Southern railway, and all traffic is suspended to Dillon, a distance of 10 miles. The French Gulch company's Reiling dredge is attacking a 50-ft. bank, and recovers up to $33,000 per month. The Wellington Mines Co. is making regular shipments of zinc concentrate. There are a number of gold, gold-silver-lead, lead-silver, and zinc claims to be had under lease and option.

Teller County (Cripple Creek)

From its Eclipse and Carbonate Queen properties on Battle mountain, the El Oro company sent out approximately 2950 tons of ore in September, worth $35,400. This was mainly from the Mullen vein, which is developing well. About 100 miners are now employed.——Ore production of the Vindicator in September was 75 carloads, that on Company account averaging $35 per ton. The Company will pay 3c. per share, equal to $45,000, on October 25. The total to date is $2,947,500.—— The Granite output was 65 cars of $25 ore. The Dillon shaft is down 1316 ft., and will be sunk to water-level, or 1500 ft. ——There are between 25 and 30 sets of lessees working on the Stratton estate, as well as several prospecting permits with lease options.——The top 40 ft. of the Jo Dandy shaft is being concreted.——The Abe Lincoln mine lessees shipped 525 tons of ore last month.——To date the Mary McKinney mine has produced $8,122,610, and paid $1,169,306 in dividends.——The Ajax company treated most of its 3918-ton output in September at the Colburn mill. The average value was $6.89 per ton. Twenty sets of lessees are at work.——From No. 13 level the Beacon Hill Leasing Co. will sink the winze to water-level.——The Jerry Johnson ore-house has been destroyed by fire.

IDAHO

The mineral product of chief value in Idaho, according to the U. S. Geological Survey, is lead, which forms about 60% of the state's total mineral production, having somewhat more than twice the value of its silver output, which ranks second among the state's mineral products. The total value of the mineral products of Idaho increased from $21,816,390, in 1912, to $24,565,826, in 1913. In 1913 the recoverable lead content of the ores mined amounted to 158,936 short tons, valued at $13,986,366, against 142,093 short tons, valued at $12,788,355, in 1912. Idaho ranks second among the states in the production of lead ores, its output of this product being exceeded by that of Missouri. The recoverable silver content of the ores mined in Idaho in 1913 was valued at $6,033,473, against $5,101,268 in 1912. Copper, gold, and zinc are also produced in significant quantities in Idaho, the output of each having a value of over $1,000,000 in 1913. The total value of the metals contained in the ores mined in Idaho in 1913 was $24,168,339. Non-metallic products were valued at $397,487.

Boise County

(Special Correspondence.)—The Gold Hill & Iowa Mines Co. is enlarging its plant with a large compressor, Nissen stamps, and Wilfley tables. The first grade of concentrate is being shipped and the second cyanided. Ore is extracted from the 250, 400, and 500-ft. levels. E. E. Carter is manager.——The Mountain Chief company has changed its method of treatment, and is now depending entirely upon cyanidation. A power-line is being built to connect with the Gold Hill line.——The Golden Age mine at Grimm's Pass will be operated this winter. ——The Boston-Idaho company has purchased the Edna mine.

Quartzburg, October 6.

Lemhi County

(Special Correspondence.)—The Lemhi county fair at Salmon was a great success. The mineral exhibits were excellent, this department being in charge of A. C. Ludwig, assisted by E. Hill, O. E. Kirkpatrick, and T. Pope. There were 70 samples of ore, coal, building stone, and stream tin, also some of the rarer ores. The tin was from Eli Minert's claim in Prairie basin. The exhibit of W. H. Shoup contained

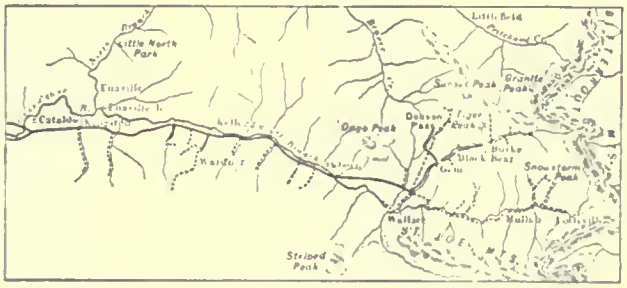
over 1000 nuggets of placer gold, and other specimens. Some of the collections will be sent to the Idaho building at the Panama-Pacific Exposition.

Development at the Wickham and O'Beness gold mine, 10 miles down the river from Salmon, is encouraging, and machinery has been installed.——According to the manager of the Musgrove Mining Co., the September profit from the Chilean mill and cyanide plant was $3000.

Salmon, October 7.

SHOSHONE COUNTY

For many years the Washington Water Power Co. has had practically a monopoly of the supply of electric power for mines and mills in the Coeur d'Alene district. But now it is reported in *The Wallace Miner* that the Montana Power



MAP SHOWING POWER-LINES OF THE WASHINGTON WATER POWER CO.

Co., whose plants are at Great Falls and Thompson Falls, is to enter the field as a competitor for business. Men are now clearing space for the transmission line which will enter the district near Mullan.

The Stewart Mining Co. has declared a dividend of 10%, and an extra one of 2½%. A shaft is to be sunk from the 400 to the 1000-ft. level. Most of the ore mined comes from above 600 ft., the daily output being about 500 tons. Also about 600 tons of 45% lead and 50-oz. silver ore is sent per month to the East Helena smelter, as is the concentrate. A flotation plant is doing good work in the mill. Net earnings for the first half of the current year were $537,230.

The 7500-ft. adit of the Montana-Idaho Copper Co. has been started from Adair station, on the Chicago, Milwaukee & St. Paul railroad, to connect with the shaft of the Monitor Mining Co. A water-power plant is being erected to supply air for drills, instead of hand work as at present. Otis Hill is manager of the first-named Company.

The Idora mine shows improvement, and the mill will soon be started by C. F. Mallette, of Spokane, who is endeavoring to clear the Company's debt.——The Paragon mill is again working and producing zinc and lead concentrate.——Mining on the north side of the Coeur d'Alene is better than ever. This may also be said of the area on the Montana side of the divide, of which Saltese is the commercial centre. Promising mines here are the Hemlock, Meadow Mountain, Tarbox, Bald Mountain, Last Chance, and others. Silver-lead and copper ores are mined. The Montana Power Co.'s line may pass through the district.

MISSOURI

JASPER COUNTY

Under the direction of Otto von Schlichten, of the State Geological Survey, and assisted by G. B. Corless, a topographic map of the Joplin district is being made. Developments up to date will be recorded.——Good results have been secured by C. A. Wright in experimenting on local mill products with flotation methods.——The Hercules Powder Co.'s fifth annual drilling contest was held at Joplin on October 4. Fourteen teams entered, and were watched by 4000 people. The winners were H. Haines and E. Haines, who drilled 37.5 inches in 15 minutes, followed by O. L. Seagraves and B. Anderson, with 36.4 in., and C. E. Smock and H. Van Horn with 35.5 inches. Prizes were $100 and $50 for first and second places. The winners also got the trophy hammer, with previous results engraved on it.——Zinc ore prices are down to $40 per ton for 60% ore.

NEVADA

ESMERALDA COUNTY

The Nevada Engineering Works of Reno is preparing plans for a 5-stamp mill for the Diamondfield Black Butte Reorganized Mining Co. of Goldfield. The plant will also contain a tube-mill, agitators, and decantation tanks. The superintendent, A. J. Canavan, estimates ore above 100 ft. in the mine and on dumps as 20,000 tons averaging $7 per ton. A net profit of $51,000 is expected. Past production is over $600,000.——The Silver Pick Consolidated 500-ft. level is being sampled by the general manager, E. S. Van Dyck, and the superintendent, Walter S. Norris.——Preparations are complete for installation of pumps at 1800 ft. at the Merger.——The Golden Arrow company, operating 47 miles northeast of Goldfield, has bought 10 stamps from the Florence Goldfield company. A 75-hp. gasoline engine has arrived from Los Angeles. E. M. Kieron is manager, and S. O. Jones, mill superintendent.

HUMBOLDT COUNTY

Extraction of high-grade ore from the Nevada Packard claims continues. Shipments from the Kraner-Hampton lease for the last half of September totaled 74 tons, worth $4697; and from Company workings 50 tons valued at $2559.——During the 18 days of last month that it was operated, the Seven Troughs Coalition mill yielded $37,000. At 1200 ft. in the vein shows 3 to 8 ft. of rich ore.——The Davey 5-stamp mill at Dantown, in the Awakening district, produced $20,000 in gold in 50 days. A 50-ton cyanide plant may be erected. H. S. Chapman is mill manager.

NYE COUNTY

The White Caps Mining Co. at Manhattan has arranged to use part of the Manhattan Milling & Ore Co.'s 10-stamp mill and cyanide plant. This will allow of a large tonnage of oxidized ore being treated.——Lessees at the Litigation Hill mine have recently crushed 50 tons of $48 ore at the Associated mill. This mill has started on a 1000-ton lot of $12 ore from lessees at the Manhattan Consolidated.

In the Bullfrog district, the Sunset Mining & Development Co. has nearly finished erecting a cyanide plant and other equipment. With the 10 stamps in the mill, there is now a 5 by 18-ft. tube-mill, four Pachuca agitators, four Dorr thickeners, and a Portland filter. An Overstrom centrifugal crusher is to be installed, which may eliminate the stamps. The mine shows 50,000 tons of $5.50 ore, which may yield a profit of $2 per ton.

At Tonopah the Jim Butler company has had an attachment for $1,500,000 served on the West End company, to cover the value of 25,000 tons of ore alleged to have been wrongfully extracted, or $500,000; also for exemplary damages allowed under the statute.——So far the Egyptian vein at 400 ft. in the Extension has been opened for 400 ft.——The Montana mill treated 1034 tons of ore last week, and 846 lb. of bullion and 20 tons of concentrate were shipped.——Ore production of the district last week was 10,482 tons, worth $211,636.

WHITE PINE COUNTY

At the Nevada Consolidated plant at McGill four of the eight units of the concentrator are operated for four or five days, then the other four are given a similar run. Only one of the four reverberatory furnaces is in blast. The September *Safety First* of the Company shows that there were only six disabling accidents during the month, one at the Veteran mine, four at Copper Flat, and one at the smelter, the mill having none to report.

OREGON

Baker County

The Greenhorn camp is showing increased activity. A stamp-mill is being erected at Tipton; the West Side mine is shipping ore. F. Roberts is milling ore from the Snow Creek mine; while assessment work is being done on the Don Juan, Bi-Metallic, and other claims.

UTAH

Beaver County

The Moscow company's output in September was 750 tons of silver-lead ore worth $15,000. This came from the 800-ft. level.——A mining committee of the Salt Lake Commercial Club has visited the new gold district of Fortuna, mentioned in this journal last month. It reports that automobiles can be driven all the way to the camp; mining claims are up Rocky hollow, and strong veins were found to outcrop prominently; dikes of eruptive rock occur; country rock is monzonite; the ore is a quartz containing gold and silver; some free gold is visible in stringers; work is being done faithfully; and the outlook is so favorable that capital should be invested to determine the merits of the properties.

Juab County

The Eagle & Blue Bell company's new shaft is down 90 ft. below the 1550-ft. level. The output is about 100 tons per day.——The Iron Blossom company has declared a dividend of 10c. per share, equal to $100,000. Development at 1900 ft. is being continued.

Summit County

The Snake Creek tunnel is now in 9436 ft. Owing to hard rock, water, and low air-pressure, the advance in September was 350 ft., compared with 419 ft. in August. Water at the portal is flowing at the rate of 9.87 second-feet.——A dispute has arisen between Solon Spiro, president of the Silver King Consolidated Mining Co., and prominent shareholders, owing to a request of Mr. Spiro for extra compensation.

Tooele County

After being dressed by concentration, a shipment of high-grade gold-silver-bismuth product will be shipped by the Wilson Consolidated Mining Co., operating in the western part of the county. This will be the first carload shipment of such ore from any Utah mine.

WASHINGTON

Okanogan County

The Palmer Mountain tunnel, and the Summit and Copper World mines near Loomis, have been bonded to Ernest Barton, of Los Angeles, California. An electric smelter is proposed capable of handling all ores from the county.

CANADA

British Columbia

Shipments of zinc ore from Nelson to the zinc smelters at Bartlesville, Oklahoma, amounted to 1012 tons during September, as follows: Utica, 33 tons; Standard, 453 tons; Hewitt, 353 tons; and Rambler-Cariboo, 173 tons.

Near Skeena Crossing, the Juniper Creek Mines Co. is developing the Great Ohio copper mine, and an adit is in 365 ft., which should soon cut the vein.

Ontario

Insurance rates on bullion from Cobalt to England are said to have been doubled on account of war risks.——During September the Nipissing high and low-grade mills treated 155 and 6404 tons of ore, respectively, while the bullion shipped was 666,027 oz. silver. Of this, $202,243 was on Company account, and $149,181 from custom ore. Mine development was satisfactory.

It is proposed to consolidate the Crown Porcupine and North Thompson claims at Timmins, and adjoining the Hollinger on the south.

Yukon

'Lode Mining in the Yukon,' an investigation of quartz deposits in the Klondike division, by T. A. MacLean, is the title of a 205 page, well illustrated publication, just issued by the Department of Mines of Canada, at Ottawa. In the season of 1912 the gold areas of Dawson, Duncan, and Conrad, and the copper belt of White Horse, were examined. Great assistance was given by D. MacLachlan. Lode mining has been attracting considerable attention in these parts for some years past, quartz claims being staked as early as 1899. Total gold output of the Klondike, including the last season, is about $180,000,000, mostly from placers. In 1900 the population was 30,000, with a yield of $22,275,000; in 1912 it was 8500, with $5,500,000, of which $9500 was from gold lode mining. With the decrease of placer gold, miners have turned to lodes, but results have been indifferent. This is partly due to the fact that prospectors were not familiar with lode mining, little or no high-grade ore had been found, capital was difficult to secure, and considerable expenditure had been made inadvisedly on certain properties. The local government has aided prospectors by road making, an assay office, and diamond-drills. Early in 1912 the Yukon Miners' Association asked the Dominion government for assistance. Mine operators are

OPEN-CUT AT LONE STAR MINE, NEAR DAWSON.

handicapped by the heavy charges for transport of supplies. The weather from June to September is splendid, and underground work may be done through the winter. Plenty of timber is available. The various mines visited are described in the volume, with the geology of the districts. The Lone Star mine is situated on a tributary of Bonanza creek, near Dawson. The Boulder lode here is an irregular formation of quartz lenses through a mass of micaceous schist, much crushed, folded, and metamorphosed. In the 1912 season, 2495 tons of ore was crushed by the 4-stamp Joshua Hendy mill, averaging $3.79 per ton. Concentrate assayed $12 per ton or more. Cost of mining and milling was $2.75 per ton. At White Horse, the Pueblo orebody, and practically all the copper ores of the district, are ordinary contact metamorphic deposits, but they are composed of cupriferous hematite in contrast to the others, which are composed of copper minerals

associated with magnetite. The Pueblo ore is in limestone near the contact of this and granite. The deposit is very irregular in shape. In the Wheaton and Windy Arm areas of the Conrad district, below White Horse and north of Skagway, are gold-silver quartz veins, antimony-silver veins, silver-lead veins, contact metamorphic ore deposits, and coal seams. Quartz is predominant. Only the highest grade ore could be shipped. The publication should be in the hands of all interested in Alaska and the Yukon.

COLOMBIA

The Pato dredge of the Oroville Dredging Co. turned over and sank on September 11. It was righted on the 17th, and was expected to be repaired by about the first week in October.

MEXICO

According to *The Mexican Herald* of October 5, there are now no metal refineries in operation in the republic, the two which were worked being closed. That of the Compañia Afinadora y Refinadora de Metales de Monterey was partly burned last April; while the French company, Société d'Afinage de Metaux, at Nonoalco, shut down its plant at the outbreak of war in Europe. A hoard of ₱200,000 of silver has been found in Mexico City and confiscated.

According to a *Daily Consular Report*, from Tampico, of September 10, practically all field operations in the oil regions have been suspended. This is due to local conditions, and also because there is no market for the grade of crude oil produced in this district. At the beginning of September there were only 27 rigs at work, against 83 actually drilling on April 20, 1914. Only 5 of the 27 are making fast time on holes. The latest national decree on oil from the port of Tampico makes the tax 8c. per barrel, against 6c. a year ago. Oil from Tuxpam escapes the Tampico 'bar' dues, which are about 25c. per ton. Oil shipments to the United States in July and August were 1,607,210 and 680,042 bbl., respectively, and a total of 2,460,008 and 1,168,340 bbl. to all points from the two ports mentioned. Oilmen in Tampico are generally depressed with the state of affairs.

CHIHUAHUA

(Special Correspondence.)—Mining in Chihuahua is very quiet at present, and until the political entanglement is settled, there is little hope for a 'Mexican boom.' In this district the only mines operating are out at Santa Eulalia. At the present time the Domingo and Potosi properties of the Chihuahua Mining Co. are operating. This Company is controlled by More and Schley, of New York. The Mina Vieja is being operated by the American Smelting & Refining Co., and the Buena Tierra by an English company. All work is on a limited scale owing to the scarcity of labor and the companies being unable to market their ores to the smelter here, which is only operating four stacks. There are no mills in the district, and the mines are producing from 300 to 350 tons per day.

The Cusi Mining Co., which is working the old Promontorio mine in the Cusihuiriachic district, has continued right through the Mexican revolutions, and is producing a very high grade of silver ore. The Company, however, can only dispose of 900 tons per month; this, it is said, being all that the smelter will take. The ore assays upward of 300 oz. silver per ton. It belongs to the Potter Palmer estate of Chicago.

Chihuahua, October 6.

HIDALGO

As the result of a fire in the Barron mine of the Real del Monte company, an explosion of 500 cases of dynamite occurred on October 3. This mine is between La Blanca and Santa Gertrudis, and is connected with the latter on No. 16 level. Smoke entered the Santa Gertrudis, which was abandoned. The total amount of damage done is not yet known.

PERSONAL

J. KOJIMA is in New York.

B. J. PADSHAH is in London.

C. S. HALEY has gone to Nevada.

A. H. BROOKES was at Dawson recently.

ROBERT H. BEDFORD is in San Francisco.

E. H. LESLIE was at Chihuahua last week.

THOMAS T. READ was at Pittsburgh last week.

SUMNER S. SMITH is expected in Oakland for his annual vacation.

F. H. MORLEY has settled at El Molino, Olive Mill road, Montecito, California, for the winter.

EDWIN E. CHASE has returned to Denver from California and resumed his consulting practice.

A. C. BAILEY has been appointed manager of the Porcupine Pet mine in Delora township, Ontario.

C. S. NEWCOMB returned to Mexico on October 15, after several months' stay in the United States.

G. C. BATEMAN has been appointed consulting engineer to the Long Lake Gold Mines near Sudbury.

W. SPENCER HUTCHINSON passed through San Francisco on his way from British Columbia to Arizona.

R. H. CHANNING, who was in France and saw some of the fighting on the Marne, was in Utah last week.

LIONEL LINDSAY has a commission in the King's Royal Rifle Corps, one of the well known English regiments.

GEORGE W. SIAS, president of the Valdez Creek Power & Mines Co., Alaska, has returned to Boston from Valdez.

RICHARD PHILLIPS has returned from the East and is now at his property, the Old Glory mine, near Oroville, California.

R. B. LAMB has moved his office from room 703 to rooms 501 and 502 in the Traders Bank building, Toronto, Ontario.

JAMES E. RUSSELL has been appointed assayer in charge of the United States assay office at Deadwood by the President.

A. W. ALLEN is revising Julian and Smart's 'Cyaniding of Silver Ores,' but is hampered by the fact that Edgar Smart is in the Belgian Congo, where fighting has interfered with ordinary pursuits.

CARL A. ALLEN and C. LORIMER COLBURN have left Denver for Breckenridge, Colorado, where they will be employed for the next few weeks in unwatering and examining the Country Boy and Juniata mines.

The Pennsylvania Railroad Co. has named its new line south from Burgettstown, Pennsylvania, eventually to connect with Wheeling, West Virginia, the Langeloth division, in honor of the late JACOB LANGELOTH, after whom the new town of Langeloth has also been named. Mr. Langeloth left a bequest of over $150,000 to be devoted to social and welfare work in the new town.

Obituary

JOHN WESLEY BOLEAU, who shot himself on October 7 at his home in Pittsburgh, was born October 27, 1873, in Athens county, Ohio. Beginning as a clerk in a store, and later becoming a school-teacher in Pennsylvania, he took up engineering and contract work, finally specializing in coal lands, of which he made large sales. He was an officer and director in many coal and coke companies, and was prominent in the life of Pittsburgh. Depression caused by ill health and the recent suicide of a friend is supposed to have prompted his act

EASTERN METAL MARKET

(By wire from New York)

NEW YORK, October 15.—The markets are weak. Lead is quoted at 3.75c. and spelter at 4.55c. per pound. While there has been no regular market for copper, settlements on October 2, 6, and 9 were 11.75, 11.15, and 11.50c. respectively. Exports for the first seven days of the month were 4805 tons, a small gain. Reduced freight rates will be granted to American imports by way of Vladivostok to Russia. Low rates obtain for American tin, nickel, copper, aluminum, zinc, and medicated cotton, according to a telegram from the consulate at Moscow. Platinum in London is $44.40 per ounce, and molybdenite $27.60 per unit.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The tendency of prices has been downward, and New York and London quotations are 51.5c. and 23d. per ounce respectively. Pixley and Abell of London, on October 1, stated that business continues restricted, and transactions are for cash only, being limited to actual demand, there being no speculative account. Exports of silver from London to India, China, and the Straits for the current year total £4,563,500, against £6,841,000 for the same period of 1913. The Nipissing company sent 315 bars, weighing 365,051 oz. silver, to London last week. The Crown Reserve sent 46,197 oz. During the last half of September the Tonopah Belmont mine yielded 76 bars weighing 155,016 ounces.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Sept. 17	75.00	Oct. 1	55.00
" 24	75.00	" 8	55.00
		" 15	55.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	80.00
Mch.	40.20	39.00	Sept.	39.70	76.25
Apr.	41.00	38.90	Oct.	39.37	....
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

Quicksilver producers faced a slump in prices last week, a result of the importation of 1000 flasks from Italy. As that amount represents about six months output for that country and Italy is likely, furthermore, to need its own supply if the country decides to engage in the luxury of war, further importations are not likely to be large for some time. The Austrian mines are working full time to supply Austrian and German demands. Spanish quicksilver goes to England, and the American market is left to the American mines without the fear of importations which has long acted as a regulator of prices. For the present there is little trading and producers and consumers are watching each other closely.

The Nevada Cinnabar Co. at Ione is producing 60 flasks of metal per week. A recent shipment to the East amounted to 355 flasks.

COPPER

Prices of electrolytic in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	12.34
Mch.	14.72	14.11	Sept.	16.23	....
Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.98	....
June	14.71	13.60	Dec.	14.25	....

The market is stagnant at 11.40 to 11.50c. per pound. It is stated that the Western Electric Co. bought 5,000,000 lb. at 12c., a week ago. Germany has paid 20c. for a shipment. The visible supply of copper in England on September 30 amounted to 24,146 tons, as follows: stocks in England, 18,610 tons; afloat from Chile, 475 tons; and afloat from Australia, 5050 tons, according to Henry R. Merton's report of October 2. On August 31 the total was 21,397 tons. Prices are about £55 per ton, the average for electrolytic metal in September being £55 19s. 4d. The Elmore plant at Sulitjelma, Norway, recovered 1489 tons of copper concentrate in September.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Oct. 8	3.75	Aug. 26	3.87
" 9	3.75	Sept. 2	3.90
" 10	3.75	" 9	3.85

May	4.34	3.90	Nov.	4.16	....
June	4.33	3.90	Dec.	4.02	....

Lead is firmer at St. Louis at 3.37½ to 3.40c. per pound. A large business has been done in England, mostly for shipment to Russia. American supplies lowered prices, which averaged £18 16s. 3d. per ton in September.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
Oct. 8	4.55	Aug. 26	5.77
" 9	4.55	Sept. 2	5.75
" 10	4.55	" 9	5.50
" 11 Sunday		" 16	5.25
" 12	4.55	" 23	5.00
" 13	4.55	" 30	4.88
" 14	4.55	Oct. 14	4.55

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	6.88	5.14	July	5.11	4.75
Feb.	6.13	5.22	Aug.	5.51	5.45
Mch.	5.94	5.12	Sept.	5.55	5.16
Apr.	5.52	4.98	Oct.	5.22	....
May	5.23	4.91	Nov.	5.09	....
June	5.00	4.84	Dec.	5.07	....

The Platteville, Wisconsin, letter of this week, on page 616, should be studied for a better understanding of the spelter situation. The metal is lower at St. Louis at 4.50 to 4.60c. per pound. Zinc ore prices at Joplin, Missouri, are weak at $34 to $38 per ton. Pressing offers from the United States have weakened the English market. The average in England in September was £25 14s. 9d. per ton.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	49.74	31.60
Feb.	49.07	39.76	Aug.	41.75	30.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.29	Nov.	39.72	....
June	45.10	30.72	Dec.	37.55	....

The tin market is stagnant, sales having gone down to 30.30c. per pound. A total of 2880 tons was due by steamer to New York up to October 14. Buying by consumers for November to March has stopped. In London, in September, standard metal fluctuated between £139 10s. and £133 per ton.

MINING DECISIONS

Coal Mines—Statutory Regulation of Weighing Coal

The Ohio law providing that the regulation of weighing of coal before screening has been upheld by the Federal Court as a valid exercise of the police power.

Rail & River Coal Co. *v.* Yapie, 214 Federal, 273. May 20, 1914.

Oil Lease—Voidable Prior to Development

Held, that where under an oil lease the lessee has the option at any time of refusing to comply with the contract and surrendering the lease without exploring and developing the land, upon the payment of a purely nominal consideration the contract is unilateral, and may be avoided at the option of the lessor.

Owens *v.* Corsicana Petroleum Co. (Texas), 169 Southwestern, 192. June 27, 1914.

Adverse Claim—Proof Insufficient

Where plaintiff, in an ejectment suit brought to substantiate an adverse claim in patent proceedings, proved the recordation of a copy of a prior location notice, but submitted no further proof of the acts necessary to validate a location, it was held that the showing was insufficient to support plaintiff's case. Proof that assessment work was performed continuously for ten years is not sufficient to support title by prescription, as such proof does not establish open, notorious, or continuous adverse possession for said period.

Childers *v.* Laham (New Mexico), 142 Pacific, 924. August 4, 1914.

Roads and Trails as Patent Improvements

Where some mining claims, for which patent was sought, were situated on the side of a steep mountain, and the construction of a trail was absolutely necessary for properly working the same, such trails may be properly counted as patent improvements. But a road or trail, no portion of which is on the claim, and which is not intended to be used in connection with such claim, cannot be accepted as compliance with the legal requirement. There must be a necessary connection between the construction of the road or trail and the proper development of the claim. Cases reviewed.

Tacoma & Roche Harbor Lime Co. (Land Decisions), 43 Land Decisions, 128. February 21, 1914.

Final Entry—Effect of Erroneous Cancellation

The legal effect of the allowance of an entry upon application for a patent to a mining claim by the local land officer issuing the final receipt is a determination that the original locations were valid and that everything necessary to keep them in force, including the annual assessment work, had been done, and the effect of such determination is not destroyed by an erroneous cancellation by the Land Department of such final receipts and entry. Where such cancellation is based on the fact that the affidavit of posting the notice of application for patent was executed outside of the mining district wherein the claim was situated instead of inside the district as required by law it was erroneous, the defect being a mere irregularity which could be cured by the subsequent filing of a properly verified affidavit, and not a jurisdictional matter as claimed by the Land Department.

El Paso Brick Co. *v.* McKnight (U. S. Supreme Court), 58 U. S. L. Ed., April 6, 1914. Reversing New Mexico Supreme Court decision in 120 Pacific, 694.

RECENT PATENTS

1,110,896.—Electrostatic Separator. Harry Comstock, Mineville, New York. Filed June 9, 1911. Serial No. 632,184. In a static separating apparatus, and in combination, a belt of nonconductive material; an electrostatically charged plate supported above the lower stretch of said belt; means for moving said belt; and an electrostatically charged belt.

1,110,790.—Apparatus for Making and Filtering Solutions, Applicable in the Extraction of Metals from Ores and for Like Purposes. Percy Claude Cameron Isherwood, Bushley Heath, England. A rotatable casing divided longitudinally by a partition into compartments, a solution discharge outlet on each of said compartments, a filter plate for each of said compartments, and man-holes to each compartment on the outer side of such plate for charging and discharging the compartments.

1,109,485.—Ore-Pulp Classifier. Joseph T. Terry, Jr., San Francisco, California. A hydraulic classifier including a weight yielding adjusting frame, an automatically leveling supporting frame movably mounted therein, a main receptacle movably mounted in the supporting frame, said receptacle being formed with a valved discharge opening and means connected to the valve and operating in the movement of the receptacle under the accumulation of material therein to actuate the valve to free the discharge opening.

1,109,533.—Machine for Removing Slag, Ash, or Other Residue from the Retorts of Zinc Furnaces. Edward W. Keith, Denver, Colorado. The combination of an electric motor having a shaft supported in hubs and provided with a drill-receiving bore in its forward end and an axial passage extending from said bore to the opposite end of the shaft, a cap on the rear hub of the motor having a chamber communicating with and providing an unrestricted inlet to the axial passage in the shaft, and a valved hose connected to said cap.

1,110,660.—Process for Arresting Sulphurous Gases and Fumes and Utilizing the Heat and Gases Contained Therein. Charles S. Vadner, Salt Lake City, Utah. Filed October 29, 1913. Serial No. 797,949. The process which consists in recovering zinc and other metals from naturally oxidized or sufficiently roasted sulphide ores containing zinc and other metals by spraying the finely ground pulp of said ores into smelter fume containing sulphurous gases, eliminating the copper contained therein by passing the solution over metallic iron, oxidizing the solution and eliminating the other metals except zinc by precipitating same in the cold by means of a sufficient quantity of finely pulverized calcium carbonate, reheating the solution and precipitating the zinc as a basic carbonate.

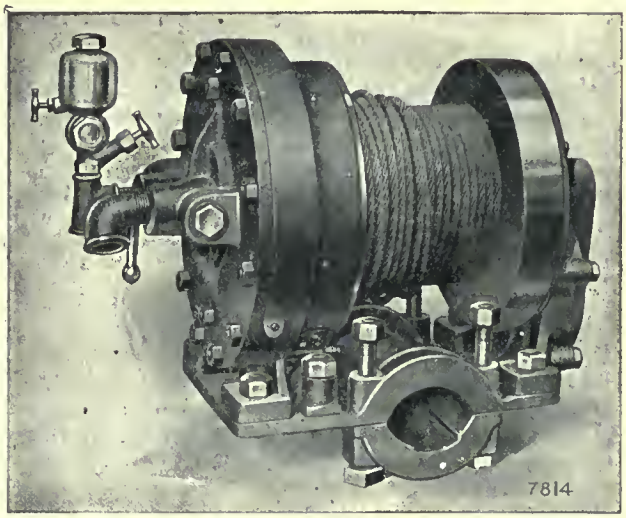
1,100,971—Concentrating apparatus. Peele T. Hambric, Drytown, California, assignor of one-half to Wilton E. Darrow, Sutter Creek, California.

A revolving frame having a series of radially disposed superposed independent concentrating tables, a mechanism for subdividing and distributing the pulp comprising a stationary pulp receiving launder mounted above the frame, an annular distributing launder centrally mounted in the frame and revoluble with same, radially disposed and downward inclined flumes connected with the annular distributing launder, vertically disposed flumes connected with the outer ends of said flumes and divide into a plurality of ducts, a series of distributing plates secured in the revolving frame adapted to deliver and distribute the pulp to the concentrating tables.

New Machines and Devices

The Little Tugger Hoist

A new hoist has recently been perfected and placed upon the market by the Ingersoll-Rand Co., which is intended for light lifting. It has a capacity up to a half-ton, and because of its light weight, which is under 300 lb. complete, it is recommended particularly for use as a portable hoist for mines, for contract work, for manufacturing plants, for power-houses, and in railroad shops and shipyards. In the mines it can be used in winzes, stopes, and rises, clamped to a drill column, stretcher bar, shaft-bar, or timber, for raising and lowering drilling machines, mountings, drill steel, timbers and



LITTLE TUGGER HOIST, REVERSE VIEW.

miscellaneous material, for hauling cars in drifts and tunnels, for hoisting and lowering ore and water buckets in shallow shafts, for placing light machinery, and for numerous other purposes.

The main base of the hoist is arranged so that it can be bolted to a timber and by means of a cap which comes with the hoist it can be clamped to a circular member, as a mine column or arm, shaft-bar, or pipe. The adjustment can be made quickly. The dimensions of the hoist are 21¼ by 16½ in. and the height is 20⅛ in. The drum is of 6 in. diameter, with a space of 7 in. between flanges. This will accommodate 700 ft. of ¼-in. rope or 450 ft. of $\frac{5}{16}$-in. The capacity is 1000 lb. at a rope speed of 85 ft. per minute and a pressure of 80 lb. It operates with either compressed air or steam. The motor or engine is of the reversible square piston type, giving four impulses per revolution. There are no dead centres. The drum is mounted independently of the engine shaft and is operated through a clutch and gears. There is a powerful worm-operated band brake lined with 'Raybestos.'

The accompanying illustration shows the reverse view, the engine being on the left. Separate levers control the gears and clutch, the direction of operation, and the brakes. These are at the front of the hoist. When the operator releases the throttle it returns automatically to central position, shutting off the power and stopping the hoist. Thus the hoist may be used for haulage purposes and this release feature enables one man to handle it. He can leave the control lever and carry the rope to the car. Hoists without this feature require two men, inasmuch as the rope has to be released under power. There are no moving parts exposed on the 'Little Tugger,' except the drum, all gears and shafts being covered. This is an especially desirable feature for underground operation where the light is none too good and where there is constant danger of workmen's clothes or bodies getting caught in machinery.

A New Ventilating Fan

A new type of ventilating fan, suitable for mills and factories, that is said to be especially effective, has been recently put on the market by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pennsylvania. The fan differs from the older style in having a large number of blades which are mounted on a wide central disk and have the ends abruptly turned up. The manufacturer states that this design has been adopted after careful study and many experiments, because it is so quiet in operation and so highly efficient. The air is thrown straight forward at high velocity, instead of being widely spread out, and no air can flow back through the centre of the fan, which often happens with the older design. The motor is specially designed for this particular service. It is entirely enclosed and protected from dust, dirt, moisture, etc. It has a high overload capacity, and readily drives the fan even against a strong back pressure from wind. This little blower can produce considerable pressure, and is suitable for forcing air out of underground and inside rooms, and other purposes.

A New Portable Drill

The Union Construction Co. has developed a new portable prospecting drill which is marketed under the name 'Type B Union Drill.' It is designed for general prospecting, well sinking, foundation tests, and similar work. The four legs of the frame are steel angle-bars properly braced and tied. This frame is balanced upon two wheels so that it can be tipped to a horizontal position for moving or a vertical when drilling. The power is furnished by a Cushman 4-cycle gasoline engine of which the heaviest piece weighs 135 lb. The heaviest part of the frame weighs 90 lb. The speed and ease with which the drill can be moved and erected are especially noteworthy. Drilling speed is 42 strokes per minute and the length of the stroke is adjustable. As the drill is the outgrowth of experience in prospecting of the engineers who build it, it is well worth investigation by those who have need for such a machine.

A Rotary Air-Compressor

Light, portable compressors are often necessary in mining districts, and one of the rotary type has been devised by the Wernicke-Hatcher Pump Co., of Grand Rapids, Michigan. It may be driven by a direct-connected high-speed motor or by belt. The rotor and rotor case both revolve, one within the other and at the same number of revolutions, and each revolves on its own axis in balance. Pockets are provided with intake and discharge valves, with suitable passages to the hollow rotor shaft. Claims for the machine are that the cooling system is reliable, a rotary motion is advantageous, and there is effective sealing of air at high pressure.

PIG IRON production of the United States during September amounted to 1,882,577 tons, compared with 2,347,867 tons in March, and 2,505,927 tons in September of last year.

"THE question of cyanide supply for gold and silver extraction," says a contemporary, "has already had much attention from those particularly interested." Thanks. We have devoted considerable space to the matter, for a fact.

EFFICIENCY engineering is a new name for an old but too much neglected branch of engineering work. Inspection and planning have always been part of an engineer's duties, but often great gain is made by devoting specific attention to one such phase of the engineer's duties. In this country, Mr. F. W. Taylor led the way in this particular. That his work has been obtaining recognition abroad is pleasant to record, and on another page Mr. H. N. Stronck gives interesting details as to the application of the 'Taylor system' in Germany and France.

NO news would be more welcome these days than of the discovery of a new and important gold district. Unusual interest therefore attaches to the announcement made this week of the finding of rich gold ore in the suburbs of Tonopah. We print in our news columns a summary of the situation, written by an experienced mining engineer. It is evidently too soon to estimate the find accurately, but in view of the favorable situation geologically and the history of the development of Tonopah, Goldfield, National, and other bonanza districts in Nevada, it is permissible to hope.

ONE of the great problems of man is the securing of both liberty and security, for the two are to a large degree incompatible. If all men have perfect liberty, then the strongest is free to strip the others of all they possess; if every man is absolutely secure in what he possesses, then he is largely cut off from opportunity to improve his position. Herein lies the fundamental problem of the labor union, for in endeavoring to secure for laboring men both more liberty and more security it comes face to face with the fact that the two can only be simultaneously obtained through class legislation which denies to the other groups of society the privileges which it confers on workmen.

DREDGING for coal is unusual, and it is even more unusual to dredge for it in a mill pond. Nevertheless the 'Laurel Line' railway is obtaining its coal in this way from the pond behind its dam in Roaring brook, near Scranton, Pennsylvania. According to a recent number of *The Colliery Engineer*, a dam was built across the brook to impound its waters for a cooling pond. After a few years it was discovered that the pond had been filled to the top of the dam with coal washed down by the rain from the mines on the watershed. A dredge was employed to clear out the pond, the coal recovered being used for the power house.

OPERATIONS of the Oriental Consolidated Mining Company in Korea are always of interest, and on page 663 of this issue is an abstract of the report of the general manager, Mr. Alf. Welhaven, for the past financial year of the Company. A great deal of interesting work is accomplished at the nine mines and many prospects. The five stamp-mills, five cyanide plants, the hydro-electric power plant, problems of fuel and reforestation, the medical department, and many other branches of a large concession, would appear to offer plenty of problems, yet the past year showed an increased profit of $51,396 over that of the previous year. The output to June 30, 1914, totals 3,537,378 tons, valued at $21,919,903, of which $5,576,995 has been paid in dividends. The Oriental Consolidated is the pioneer American enterprise in the Far East.

JOPLIN ore producers are disturbed at the arrangements under way to treat Australian zinc ores in this country. It is natural enough that our leading zinc producing district, one which, moreover, long enjoyed a virtual monopoly, should prefer not to see a newcomer enter the lists. In this case, however, we think there is little to fear. The Broken Hill district is already in the field and it has been one of the most surprising features of recent metal production that the great increase in spelter due to successful treatment of Broken Hill tailing, has been absorbed with so little disturbance of the world's markets. Smelting Australian ore in the United States rather than Germany will not increase the total amount of metal produced, though it will temporarily emphasize the effect of German consumers being cut off from the market. We wish we could hope to see the smelting continue in this country. However, plans

are already under way for the building in Wales of the largest and most modern zinc smelter in the world, to treat Australian ores mainly and to supply metal to the English market especially. Mr. Theodore J. Hoover, who some years since conducted important experimental tests on treating these ores in a small plant, is even now in the United States arranging for assistants. If any Australian ore continues to come here after the war, it will probably be smelted in bond and the spelter exported. Joplin will always have advantages due to the grade of concentrate produced and will continue indefinitely to be a large factor in the zinc industry.

PROGRESS OF ELECTRICAL PRECIPITATION

Announcement that the International Smelting & Refining Company had decided to commute by cash payment the future royalties on use of electrical precipitation at the Tooele plant, calls attention to the rapidity with which that process is finding place for itself. Some months ago a cash payment of $45,000 was made to the Western Precipitation Company, which controls the rights in California and Arizona, for use of the process at the new plant at Globe. While the amount paid for the Tooele rights has not been made public it is currently reported that, with the future payments, the total will be about $75,000. An interesting feature of the case is the fact that this money, together with that subsequently realized from plants in states other than the two excepted, will go to the Research Corporation, a unique organization under the patronage of the Smithsonian Institution and designed to promote research through perfecting and securing adoption of useful inventions. It is a scientific institution endowed through the generosity of Mr. F. G. Cottrell and other inventors who have conveyed to it important patent rights.

The Research Corporation already has several Cottrell plants working or under construction. At Perth Amboy a plate plant is operating on fume from the slime furnaces and a pipe plant is under construction. One pipe 24 inches in diameter and 20 feet high, the largest yet built, is being erected for testing. The Bethlehem Steel Company has a test plant of seven pipes 10 inches in diameter. The Pennsylvania Salt Manufacturing Company is using the treater on acid gases between the Glover tower and the lead chambers. The Grasselli Chemical Company has a small pipe treating hot burner gases at a sulphuric acid plant. The American Smelting & Refining Company is building a large plant at Garfield, Utah, has plate treaters working on sulphuric acid fumes from parting kettles at Omaha and Baltimore, is testing electrical precipitation against bag-house work at Murray, Utah, and is experimenting at various other plants. The Company, by the way, was the pioneer in adopting this process for smelting plants, the Selby being the first big works to be equipped. Among companies that are investigating the system may be mentioned the Balbach Smelting & Refining, International Nickel, Dusquesne Reduction, Chase Rolling Mill, Union Carbide, National Lead, Metals Refining, and the American Steel & Wire. Some of these have small test plants in operation while others are as yet merely collecting data as to character and amount of gases to be handled. The Anaconda company has a plant precipitating arsenic and is conducting tests on the main flue gases. The arsenic plant is interesting. The heated gases are first run through one pipe in which the solid particles of dust are precipitated, then cooled so that the arsenic becomes a solid, and run through a second pipe where the pure arsenic is precipitated. Another odd use of the process is for throwing down milk powder in the north side plant of the Milk Flour Company at Chicago. The Development & Foundry Company at Niagara Falls uses it to precipitate calcium chloride, and a number of detinning plants have found it useful. The U. S. Bureau of Mines at Pittsburgh is carrying on elaborate studies to find further fields of usefulness. In Germany electrical precipitation has been adopted in the acid works at a number of the larger metallurgical plants, and Mr. W. G. Schmidt has just returned from a trip to that country, where he was pressed into service in equipping plants rushed to completion after members of the regular staff had gone to war. The use in California of electrical precipitation in dehydrating crude petroleum and to clear the dust out of cement kiln gases has been previously noted. It is evident that the process has already conquered a wide field and that it probably will be used even more widely as its possibilities become better known.

THE HOUGHTON MEMORIAL

Upon a hill overlooking the waters of Lake Superior where they touch the shore of Keweenaw point at Eagle river, there now stands an impressive and permanent monument to the memory of Douglass Houghton, scientist, explorer, and Michigan's first state geologist.

It is rarely that man in his lifetime accomplishes as much as did Douglass Houghton in his short life of 36 years. When but 19 years old he was appointed assistant professor in chemistry and natural history at the Renssaeler Scientific School at Troy, New York. Before his twentieth year he was called to Detroit and began his public lectures on the sciences of chemistry, botany, and geology. A few months after his arrival in Detroit, he received the appointment of surgeon and botanist to the expedition to discover the sources of the Mississippi. It was on this expedition that Houghton acquired his first knowledge of the upper peninsula of Michigan. For four years he practised as a physician, surgeon, and dentist in Detroit. In 1837 Houghton planned the geological survey of the state of Michigan. He proposed organization of departments of geology, zoölogy, botany, and topography, each having its official head, and all united under the general direction of the State Geologist. The survey was created by law and Houghton immediately made geologist. Beginning with a reconnaissance of the state in 1837, four seasons were spent in exploring the lower peninsula, portions of the

upper peninsula on Lakes Huron and Michigan, and the southern coast of Lake Superior. Houghton's brief but clearly and cautiously prepared reports to the legislature attracted wide attention to the Lake Superior mineral lands, then an uninhabited wilderness. His last report, published in 1841, gave to the world the first definite information of the occurrence of native copper on Keweenaw point. Houghton also discovered the possibilities of the saline deposits of the lower peninsula. When the limited funds of the state compelled a suspension of the geological survey, Houghton conceived the idea of a thorough geological, mineralogical, topographical, and magnetic survey of the United States in connection with the government linear survey. He undertook this work in Michigan and his plan was tested with success before his death. Soon after his appointment as geologist, the regents of the State University appointed him professor of geology, mineralogy, and chemistry. He was twice elected mayor of Detroit and was proposed for governor.

It was on October 13, 1845, while returning to Eagle river from a visit to his surveying party, in an open boat during a heavy gale and snowstorm, that Douglass Houghton lost his life. When the news reached Detroit, a bill was introduced in the legislature asking for an appropriation for a monument to be erected on the shore of Lake Superior near Eagle river. Because of the financial condition of the state no action was taken on the bill. Alvah Bradish, in his 'Memoir of Douglass Houghton,' 1889, says: "If it is surprising, it is hardly creditable, that the monument contemplated by the legislature of '46 has not been followed up by some popular action. One would expect among the enterprising and intelligent citizens of the upper peninsula especially, that almost a spontaneous expression in this direction would have been seen before this date. A few years hence passengers traversing the waters of Lake Superior, from the deck of steamers will scan the southern shore along the coast near Eagle river—they will look for some sign that the memory of such a man has not been forgotten. The time is soon to come when they will discover some monument looming through the mist, perhaps a single granite shaft, broken midway, as the life of Houghton was shattered and broken."

Today a monument stands within a mile of where Houghton lost his life, erected by popular subscription through the efforts of the Keweenaw Historical Society. The base is made of pieces of characteristic rocks of the copper and iron country. Upon the base rests a large mass of the Keweenawan greenstone, imbedded in which is a tablet, made of Lake Superior copper, with a relief reproduction of the painting of Houghton by Bradish. Houghton is seen standing on a rocky shore with a geological pick in his hand and his dog Meme at his feet. The ground for the monument was deeded to the Keweenaw Historical Society by the Cliff Mining Company, and the construction work was done by the Keweenaw Copper Company. The dedication of this monument was the occasion for one of the greatest gatherings in history of the early pioneers of the 'copper country.'

FERRO-MANGANESE

During 1913 over 128,000 tons of ferro-manganese, of an average declared value of about $45 per ton, was imported into this country, for the simple reason that it can be bought abroad to better advantage than it can be made in this country. When the war cut off foreign supplies the quoted price jumped, in a little while, to $140 per ton, but soon afterward declined to less than $70 per ton. The *Wall Street Journal*, in a recent editorial, uses this circumstance to point a moral and adorn a tale, as follows:

"Ferro-manganese is used in the manufacture of steel. The total amount consumed here is not large—about 240,000 tons per year. But, like the salt in the soup, it is essential. Steel manufacturers must have it. Russia, India, and Brazil are the sources of supply. The first shock of the war sent the price up to $140 per ton. Later it climbed down, and now is around $68. With a prospect of shortened demand, it bids fair to go lower. Why is it declining? And why did the U. S. Steel Corporation dispose of a part of its stock at around $100 per ton?

"Taken by itself, the declining price of a commodity of which so little is used might be only a cloud no larger than a man's hand. But if we were not so much absorbed in whistling (not hustling) for foreign trade, forming government mercantile marines, and cotton panhandling schemes, we might see how it reflects danger to our greatest industry and to the country in general.

"Before this war the steel business was far from encouraging. Today the mills are running at an average of one-half their capacity. They are not stocking up with fuel, ferro-manganese, and raw materials when the prospects of marketing their finished products are dark. The railroads are the greatest consumers of steel. When they cease to buy, the steel industry must slow down.

"The railroads did not quit buying steel because they did not want it or need it. They are more like the people who look in the shop windows and wish they had the money. They want the steel, and need it. If they could buy according to their needs, it would be one of the best panaceas ever administered to a sick and depressed business community.

"Why can't they buy? Aren't they rich and powerful? No. A railroad's buying and borrowing capacity is dependent upon its earning power.

"Their present predicament is rather like that on Mount Carmel, when a deluded priesthood prayed from morning till afternoon to the god they had mistakenly worshipped, 'Oh, Baal, hear us.' In this case 'Baal' failed to recognize the country's need.

"Meanwhile the railroads wait, and unemployment is on the increase. This is what is meant by the decline in ferro-manganese."

This sounds like a powerful argument, but a little real knowledge of the situation gives the matter a somewhat

different aspect. The prosaic fact is that the steel companies when they no longer could get ferro-manganese at a reasonable price, soon found that they were not nearly so dependent on it as they had supposed. Thus one of the largest steel companies, which had been making 50,000 tons of open-hearth steel per month, and using a correspondingly large quantity of ferro-manganese, found that by making a slight change in its practice it could cut down its ferro-manganese consumption to only 300 pounds per day, using instead the spiegeleisen of which it had a large stock lying in its yards. Ferro-manganese can easily be made in this country, and the Noble Electric Steel Company has already begun its manufacture in its plant at Heroult, California. There are ample reserves of manganese ore in this country; they will be developed as soon as, and no sooner than, it is possible to secure the necessary adjustment between production cost and sale price.

SELLING MINING PROPERTIES

A mining engineer who spends nearly all his time in the valuation of mining properties for large financial interests recently expressed the belief that the chief reason why the business of financing mining properties is so dull is because in nearly every instance mining properties are submitted to possible investors under circumstances and on terms which would not merit a moment's consideration with any other form of investment. In selling real estate, for example, no one would expect to gain even a hearing from investors unless he were able to produce a valid and properly guaranteed title to the land in question, accurate surveys of the property, a map showing its exact situation, and a set of verifiable statements as to the reason why the property is of value. The title to mines offered for sale is all too frequently open to doubt, an assay map of the workings is rarely available, and any exact records of width stoped, metal content, and amount recovered from such ore as has been mined are as rare as snowballs in midsummer.

There comes to mind the case of a good sized mine which had been paying dividends for some time, but which did not regularly employ a surveyor. When it was proposed that the recent workings should be mapped it was found necessary to survey the whole mine, since the preceding surveyor had made a very attractive map of the workings, but had not established anywhere, in or about the mine, any permanent marks to which the survey could be referred. Needless to say, there were no records of the tonnage stoped in past years or its assay value, and development work in that district was frequently guided by the recollections of miners who recalled that in abandoned workings good bunches of ore appeared to pitch in this direction or that. The record in the books of such a company showing the operating expenses and the net profit could not be relied on as an indication of the probable value of the mine, since a period of good profits might indicate the mining of rich ore and the expenditure of large sums in development work, or the mining of low-grade ore without doing development work.

Suppose such a property were offered to an investor at a price of $500,000. No one could decide from an examination of the records whether the property was worth $500,000, $750,000, or $250,000, and it might easily cost the prospective investors $5000 or more to determine the probable value of the mine. From the standpoint of the investor, this is exactly like asking him to bet $5000 to nothing that the valuation put on the mine by the owner is conservative. No bond salesman of a banking house would approach a possible investor with the proposal that he should spend $10 per each $1000 bond in order to learn whether the bonds were worth $1000, $1500, or only $500 each. Some reasonable assurance would have to be given that the bonds were worth the price asked before the investor could be expected to spend any money in assuring himself that the investment was a good one. In years of mining excitement people can be found to pay large sums for mines, in exactly the same spirit in which they will bet 10 to 1 that their favorite horse will win a race, but when it comes to selling developed or partly developed properties to investors who have made fortunes through the exercise of business skill and foresight a different set of conditions must be observed.

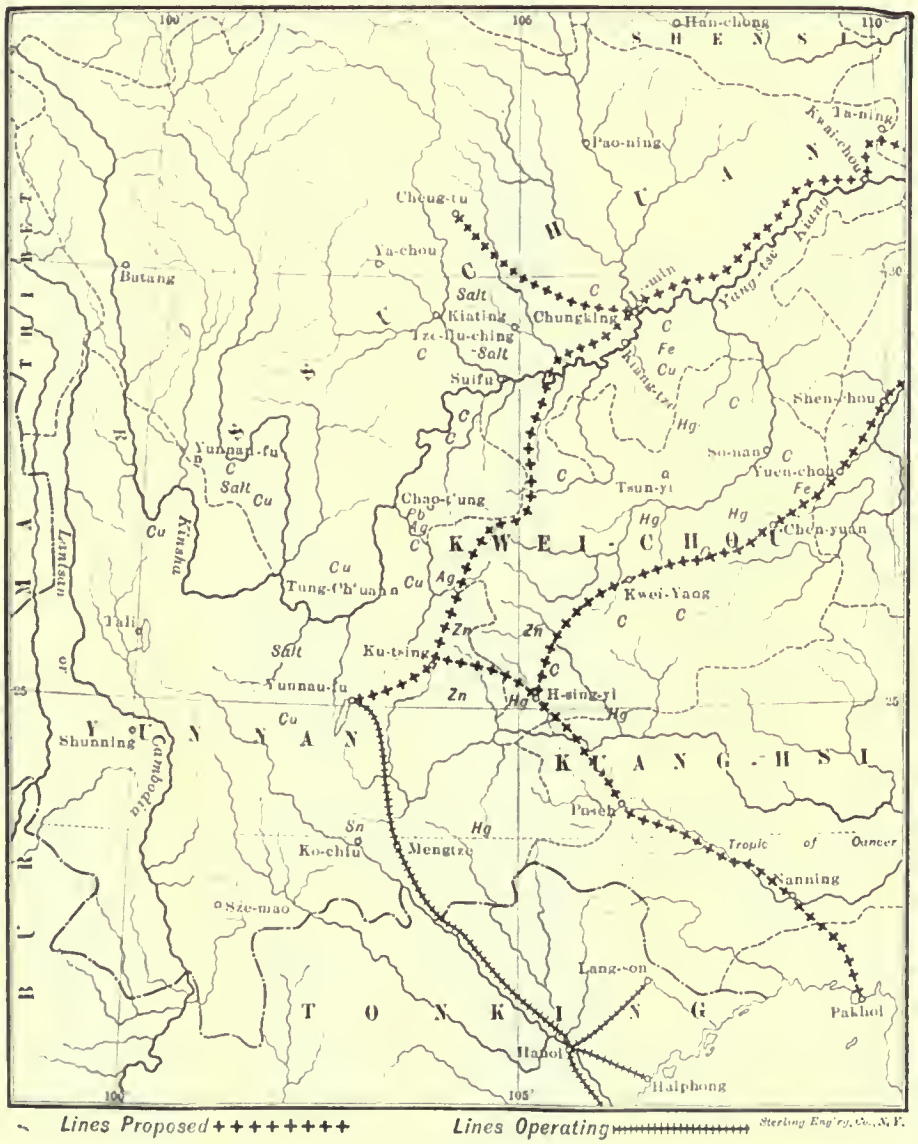
Recently one of our correspondents remarked that one of the best uses to which the Harrimans and Morgans of the financial world could put their ample funds is to expend a part of them in developing mining properties. But the miner is rarely able to get the investor's viewpoint regarding this. The small mine owner who has often skimmed the narrow edge of bankruptcy throughout years of struggle and whose cash assets only slightly exceed the month's payroll, is almost certain to think that any man with a million dollars ought to be willing to spend from $5000 to $25,000 to convince himself that the mine is worth as much or more than is asked for it. The experienced investor, however, knows that an owner is as apt to overvalue his mine as a man is apt to overvalue his dog. The millionaire who has made his money by careful investment is less likely to risk several thousand dollars on a long shot (except at the occasional solicitation of a personal friend) than is a man with only a little money. When a mine owner approaches such a man with the proposal that he spend $10,000 to $25,000 in development work, with the option to purchase the mine at an agreed price if the development work proves encouraging, he is commonly received in the same spirit that he would be if he brought into the investor's office an oil painting which he offered to sell for $10,000, claiming it to be a genuine 'old master.' Unless the mine owner can produce definite and accurate data that indicate a reasonable probability that his mine is worth somewhere near the price asked, he is not likely to be able to awaken the interest of possible investors. Records of the necessary data can be made at a slight additional cost during the progress of development work; the mine owner who neglects to make them is spoiling his chances of selling his mine at a fair figure.

Petroleum, Gas, and Brine Wells of Ssu-chuan, China

By THOMAS T. and M. CARLETON READ

The agreement made last year between the Republic of China and the Standard Oil Co. of America for the exploration and development of the petroleum resources of the provinces of Chih-li, Shansi, Shensi, Kansu, and Ssu-chuan has led to an awakening of interest in deposits which are comparatively little known. One of us has elsewhere summarized[1] the data available as to petroleum in China, which is naturally somewhat vague, as it was not until recently that petroleum has been an object of search. The best known district is in Ssu-chuan, where in drilling wells for brine, gas and petroleum are also found in less amounts, and the gas is utilized for evaporating the brine. The most famous district is that west of Tze-liu-ching, in east-central Ssu-chuan, about 100 miles west of Chungking, the chief port on the Yangtze, and an equal distance south of Cheng-tu, the capital of the province. From Tze-liu-ching, which takes its name from an old brine spring, the salt belt stretches about 20 miles southwest and has an approximate width of 10 miles. Salt is found in a great many other places in Ssu-chuan, as shown on the accompanying map, but a description of this single district will suffice. It has been briefly discussed by Alexander Hosie,[2] who visited it in 1882, and also by E. H. Parker, who has described it in the *Journal* of the Royal Asiatic Society. The most detailed description is that of Louis Coldre, who during his many years of service as *missionaire apostolique* in that part of Ssu-chuan had ample opportunity to secure accurate information which he has embodied in an important paper.[3] What follows is based on a translation of this paper which one of us has made. The illustrations are taken from M. Coldre's paper, and the notations as to the distribution of minerals, on the map, are those of Alexander Hosie, with some additions of our own.

[1] 'Mineral Resources of China,' *Trans.* Amer. Inst. Min. Eng., Vol. 43, p. 1.



MAP OF SOUTHWESTERN CHINA.

Ssu-chuan is the largest of the 18 provinces of China, having an area of over 200,000 square miles or almost exactly that of France. Its population is about 70,000,000 people, or almost double that of France. The western half of Ssu-chuan borders on Thibet and is so elevated and mountainous that it is highly inaccessible and supports but a scanty population. Compared with this rugged region the eastern half is more in the nature of a Piedmont plateau or, more strictly, an elevated basin, of a roughly triangular shape, with mountains on the three sides. The surface of the basin consists generally of Tertiary sediments, chiefly thick deposits of red clayey sandstones and sandy clays, from which Von Richthofen named the region the Red Basin. The geology is much more complicated than this brief statement would indicate, for much of mountain-making movement is post-Tertiary, but for present purposes this will suffice. The region is far distant from the

seacoast, and being difficult of access because of the mountain barriers already mentioned, salt, that universal necessity of human diet, can only be obtained from the seacoast at high cost. The tribes living between this area and the seacoast have at many periods in history been at war with the Ssu-chuanese, and as the region is a rich and fertile one, supplying almost every other human necessity, the people naturally proceeded to develop a local salt supply; which they did at an early period, probably earlier than the third century, A.D. Salt springs, appearing at the surface, doubtless gave the suggestion of boring down to increase their flow, and as a very profitable trade in salt with adjoining regions was built up, an elaborate technology was developed which is somewhat astonishing to anyone who is inclined to believe that nearly all really useful technology has been developed by Anglo-Saxons in the past few centuries.

In most places the brines are found in Triassic sediments, but in the Tze-liu-ching district the strata seem to be much faulted; at any rate the brines are found beneath the Carboniferous strata and even deeper in the series. The petroleum occurs high in the series, while gas in strong flow is found well below the top of the Carboniferous, just before reaching a thin seam of coal. The following typical section at Tze-liu-ching is given by M. Coldre.

Tertiary sandstone, yellow, 100 to 300 ft. thick.
Limestone, gray.
Sandstone, red.
Oölite, orange colored, ferruginous, with petroleum at 600 feet.
Limestone, earthy white, fossiliferous.
Limestone, yellowish, fossiliferous, with weak flow of gas at 800 feet.
Marl, bluish gray, irridescent, white Permian chalk, with brine, 12 to 15%, at 1000 to 1800 feet.
Carbon or coaly, calcareous sandstone.
Brilliant brown Silurian sediments.
Schist, black, slaty.
Schists, greenish (Cambrian), with strong brine and strong flow of gas at 2500 to 3300 feet.

The strongest flows of brine and gas are found at these greater depths in the Tze-liu-ching district, and the upper brines, elsewhere important, are quite inconspicuous in this region. Owing to the disturbed condition of the strata, layers of basalt or red porphyry are sometimes encountered in drilling, and cause much difficulty.

Petroleum

Petroleum, gas, and brine all three, two, or only one of them may be found in any given well. Where the gas flow is strong the well is capped as noted later, when the gas is unimportant the petroleum and brine are drawn off together into reservoirs. The petroleum rises to the surface of the brine and is skimmed off. It is of a variety of colors. Some is milk white, pure enough to burn with a good light; a greenish white variety is less useful; a darker yellow still less; and a viscous black variety gives little light and much smoke. The Chinese know nothing of the art of refining this petroleum, and burn it just as it is in crude lamps, made so as to have no opening except that which is plugged by the wick, as the volatile hydrocarbons which remain in the oil are very inflammable. The Chinese also use the petroleum as an ointment in certain skin diseases and for rheumatism, just as the crude petroleum of Pennsylvania was at one time used. There are 30 to 40 of the petroleum wells in the Tze-liu-ching district and about 50 in the whole province of Ssu-chuan. It must be remembered that neither the petroleum nor gas are the objects of search by the Chinese, but are merely incidentally discovered in drilling for brine. It is quite possible therefore that petroleum may be found in much more abundant amounts if exploration is directed toward its discovery.

Gas

The gas is of more importance to the Chinese, as it is used in evaporating the brine. The gas is found at two horizons. The flow at 600 to 800 ft. in depth is not very strong and the gas from a single well, burning with a white flame, will only serve to heat 15 evaporating pans. But that which comes from a depth of more than 2000 ft. comes out in a strong flow, so that a single well will serve for heating 600 to 1200 of the evaporating pans, which are shallow segments of a sphere, 4 ft. in diameter and weighing about 1600 lb. each. The gas is not rich in carbon and burns with a blue flame, giving much heat and little light. The gas sometimes contains sulphur compounds. When the drill breaks through into the gas zone the pressure of the gas hurls it out of the drill hole, and occasionally the gas ignites, if any fire happens to be nearby. The putting out of a burning well calls for great ingenuity on the part of the Chinese, and is only accomplished with much expenditure of effort.

In order to use the gas supply of a well the drill-hole casing, described later, is removed to a depth of 10 ft. Then a truncated cone of heavy beams, the apex at the top, is placed over the drill-hole and earth mixed with lime is rammed down hard around it. This is covered with a lid of beams with a large spigot in the centre to allow the gas to escape while the arrangement is being connected. From beneath the lid numerous conduits made of hollow bamboos cemented together lead off to distributing reservoirs set about on the surface. These are made of lime cement, and are hemispherical in shape, a salt cake being used as the centre for the crown of the arch. From the side walls of this reservoir bamboo tubes lead off to the evaporating pots. Beneath these are conical stones with a hole in the centre through which the gas escapes, burning at the top. A good deal of gas escapes unburned into the air, and not a little leaks out at various places. Beggars sometimes dig a little hole at a crack in the ground near a gas well, light the gas which escapes, and do their cooking over it. In some places the flow of gas is more abundant than there is use for and the excess is led to a safe distance and there allowed to escape through a large burner, the flame rising to a height of 8 or 9 ft.

In those cases in which the gas burns with a luminous flame it is used to some extent to illuminate the sheds where salt-making operations are carried on. It is not used for lighting the streets of the villages, as has sometimes been asserted. Some of the wells cease to yield gas after a time, in the ordinary way; others have been choked by the materials thrown into them by the rebels in a local rebellion. In this way one of the best wells has been ruined. By careful management, more efficient apparatus, and arrangements for piping gas and brine, so that the proportionate amounts of the two available at any one place come to be better adjusted to each other than at present, it would be possible to evaporate much more brine with the present supply of gas. M. Coldre has estimated that five times the present output could thus be made. At present other forms of fuel are used at those points where the gas is not convenient. All sorts of dried vegetable material are used for this purpose, corn stalks, pea and bean vines, marsh hay, and other materials of the same sort. Wood is not used much, since, as elsewhere in China, it is comparatively expensive. Coal, which is abundant in this province, but which usually occurs at some distance from the salt wells, is, however, used to a considerable extent.

Salt Wells

As already stated, the production of salt in this province is very great, and has been estimated at 1,000,000 tons per year, sufficing to meet the needs of the 70,000,000 people of the province and permit a brisk trade with adjacent regions. Those familiar with the salt industry in this country will at once notice that the Chinese do not use as much salt per capita as we do. M. Coldre has estimated the total number of salt wells as 10,000. The yield of brine from these wells is very unequal; thus the best well at Tze-liu-ching yields nearly 500 times as much salt as some of the other wells of the district. In some districts the wells average enough brine daily to keep five or six evaporating pans going. In other districts several wells are required to furnish brine enough to keep one pan going.

Drilling the Wells

The method of drilling and pumping these wells is so ingenious, and is so obviously the crude prototype of modern oil-well drilling that it is worth while to describe it in some detail, and the accompanying illustrations, reproduced from M. Coldre's paper in the *Annales des Mines*, will be of much interest in this connection.

Location of Wells.—There does not appear to be any scientific basis upon which the Chinese fix the location of proposed wells. The first wells were drilled near salt springs to increase their flow, and have spread outward, drilling having been done only in the vicinity of productive wells. The local wise men say they draw their inferences from the direction of the hills and the slope of the hillsides. It is quite possible that intelligent study of the areal geology would reveal one or more valuable unknown districts.

Drilling.—In starting a well a small round shaft is sunk to rock which is hard enough to stand the friction of the rope in drilling and the subsequent bailing. In the district we are discussing this shaft is commonly 100 ft. deep. This is then cased up with square rocks 2 or 3 ft. on a side through which a 10 or 12-in. hole has previously been cut. This is shown in Fig. 1, where three men are carrying such a casing stone toward a well which has just been cased to the top. As the stones are set in place the space between them and the shaft is filled with stones and well rammed earth. The hole is then rigged for the rope drilling which is to follow. A horizontal roller is rigged up at a convenient height to serve as a crown sheave. The winding drum, seen to the right in several of the pictures, is built of bamboo and is 8 to 12 ft. high and often 20 ft. in diameter. The construction of the wheel and the purpose of the sheave set midway between it and the hole is evident from the illustrations. The drilling is done with a 1-in. hemp rope and the construction of the drill bit is evident from Fig. 5 and Fig. 6. It is interesting to notice the double jars in Fig. 6, the sinker bar descending through them strikes a blow on top of the drill bit after it has struck its blow and comes to rest. The cord seen twisted about the string of tools in Fig. 5 is used to prevent loss of the drill bit, which weighs 200 to 300 lb., in case the jars break. The method of drilling is seen by referring to Fig. 7. The string of tools is hung from the key, which may be seen just above the mouth of the hole, which is suspended from a hook on the end of a lever made out of a thick plank. This is so adjusted that the lever is horizontal when the bit just touches the bottom of the hole. The four workmen then jump on the plank, depressing it and raising the bit a couple of feet. When they jump back on the side benches the bit falls. The man at the hole twists the string of tools in the usual way, and pours water into the hole when necessary. By jumping two at a time and passing from one side to another the men are able to drill at the rate of 12 to 15 strokes per minute. As the hole becomes deeper and the work harder, the number of men is increased up to 10 per shift. Two shifts are always on hand; each works 10 minutes while the other rests. The workmen were given their food and lodging and were paid 1200 cash (about $1.25) per month in 1891. The wages are probably somewhat higher now.

The operation of removing the sludge with a sand-pump, made of hollow bamboo weighing about 65 lb., is seen in Fig. 4. The men seen hanging on the rope are working the pump up and down to make it fill. Water is cased off with a bamboo tube. Fig. 9 shows the workmen making this tube, and Fig. 3 shows them lowering a section into the hole. This is 10 to 30 ft. in length and the joints are made water-tight with a cement made of tung oil and chalk. The rest of the drill rig is also built at this time. When the casing is securely in place, drilling is resumed with a smaller bit which makes a 3½ to 5-in. hole in some cases, but more often one which makes a 6½ to 8-in. hole. Deep drilling re-

quires the bit shown in Fig. 6. This is so constructed that the sinker bar, weighing 130 to 165 lb., strikes the top of the bit at each stroke, thus giving a double blow. At *K* is seen a small clapper which gives a sound which can be distinctly heard at the mouth of the well. When it is not heard, the man at the top knows it is time to let down more rope. Drilling continues in this way till the well is finished. The shallowest well in this district is 600 ft., the deepest 3500 ft.; most of them are 2500 to 2800 ft. deep. The cost of drilling a well is $6000 or more, according to the depth and the difficulties encountered, and is usually financed

by a sort of joint stock company, which calls assessments as more funds are needed. Fig. 12, which shows some of the tools used in case of accident, needs no explanation.

Salt Making

The brine wells almost never flow, and they are pumped by the continual use of the sand-pump, using a special one, often nearly a hundred feet long, for this purpose. This is hoisted by the windlass, worked by water buffaloes, seen to the right in Fig. 8. These beasts are driven at a gallop by the liberal use of a rope's end, but they are poorly suited to moving at anything except a very slow rate. The cost of their keep is rather high for China, and they do not make a very efficient power plant. It would seem that a light, cheap steam hoist would be more satisfactory, or even an air-lift pumping plant for the most productive wells. The clarification of the brine, its evaporation in open pans, and the marketing of the salt would carry us too far from the limits of our theme, but it involves many interesting details and ingenious methods of procedure. The cast iron pans used for evaporating the brine are, for instance, not owned by the salt works, but are rented from the iron mongers, who replace them as soon as they show cracks or any other defects.

Marco Polo visited this part of China in his travels, about the year 1290, and in describing customs in this portion of Ssu-chuan makes the following observations: "The money matters of the people are conducted in this way. They have gold in rods which they weigh, and they reckon its value by its weight in *saggi,* but they have no coined money. Their small change is made in this way. They have salt which they boil and set in a mold (flat below and round above), and every piece from the mold weighs about half a pound. Now, 80 molds of salt are worth one *saggio* of fine gold, which is a weight so called. So this salt serves them for small change." As a *saggio* is $\frac{1}{8}$ oz., this would make the currency value of 1 lb. of salt at that time about 8⅓c. in our money. It is interesting to notice that Polo gives the rate of exchange there as 8 oz. silver for 1 oz. gold.

Mining in Ceylon is limited to graphite and gem production. Plumbago exported in 1913 amounted to 28,997 long tons, against 32,563 tons in 1912. The average price was $103 per ton. There were 1335 pits and small pockets worked, employing 9553 men. Rubies, sapphires, garnets, and moonstones are recovered from mines, and pearls from the sea. Gem mining is carried on in a primitive manner, evidently better than hydraulicking, as an English and a French company, which failed, found out.

Coal output of Alabama last year, 17,678,522 tons, worth $23,083,724, was about 66% of the total mineral output. The pig iron made was 1,924,762 tons, worth $23,242,374; coke, 3,323,644 tons, valued at $9,627,170; and total output of all products, $34,660,545.

Getting Land for Taxes in California

When the taxes on real property have not been paid for five years or more, the land is sold to the state and the deed filed with the Controller. The state may thereafter dispose of such land in the following manner: the Controller, by written authorization, directs the Tax Collector of the county in which the property is situated to sell said property at a public auction. Notice of said auction sale must be published for at least three successive weeks in a newspaper in that county, and a copy thereof mailed to the party to whom the land was last assessed next before the sale at his last known post-office address. At the time set for the sale the Tax Collector must sell the property at public auction to the highest bidder for cash, and thereupon execute a deed to him conveying all the right, title, and interest of the state in and to said property, provided that the amount paid must equal the amount of accrued taxes, delinquencies, interest (at the rate of 7%), and expenses of the sale. Persons desiring to buy property which has been sold to the state for taxes should make written application to the Controller of the State at Sacramento, requesting him to authorize the county Tax Collector to sell the land. He should be given such a description as will enable him to identify the property in his records.

The Nevada One-Man Carry

At the Labor Day first-aid and mine-rescue celebration at the University of Nevada in September, one of the interesting events was the demonstration made by E. P. Cullinan, chief electrician of the Tonopah Belmont company, of his method by which one man can carry two unconscious men from a mine, although the burden may be more than twice the weight of the rescuer. To illustrate his method, Mr. Cullinan, who weighs 140 lb., placed two men on the ground, the first on his stomach and the other in the same position on top of him, with arms extended forward over and beyond the shoulders of the first man. Taking a position at the head of the two men, Mr. Cullinan raised their heads and bodies to an angle of about 45°, then loosening his hold he ducked under them as their bodies fell, and caught them on his back. Then securing a lock hold at the knee and arms, he rose with the two men on his back, and in that position was able to carry them a considerable distance. The combined weight of the two men whom Mr. Cullinan carried was 335 lb. The method has been named the 'Nevada one-man carry,' and is a distinct innovation in mine-rescue work.

Bullion received at the San Francisco Mint during September amounted to 240,143,834 fine ounces of gold, and 181,088 fine ounces of silver, valued at a total of $5,060,222.25. Coinage executed was $4,549,270, in gold, nickel, and bronze. Coin, bullion, etc., on hand at the end of the month was $249,393,587.41.

The Function of Lead Salts in Cyanidation

By G. H. CLEVENGER

Lead salts are used in cyanidation, either for the purpose of increasing the extractive power of the solution or as an aid to precipitation. The addition of a lead salt for either of these specific purposes does not necessarily mean that lead will be present to function in the other capacity, for, when the proper proportion is used to give the maximum extraction, there may be little or no lead present in the solution when it reaches the precipitation stage; and, when used to aid precipitation, metallic lead is precipitated by the zinc, and, therefore, remains with the precipitate.

Lead Salts and Precipitation

The zinc-lead couple for the precipitation of gold and silver from cyanide solutions was first proposed by MacArthur[1] in 1894, but, except where there was copper in the solution, it was found to be of so little advantage with the strong solutions then in use for the treatment of sand that it was rarely used.

In 1898 Betty[2] developed a method for precipitating very weak cyanide solutions containing gold through the revival of the use of the zinc-lead couple, as proposed by MacArthur, and the addition of a drip of strong cyanide solution at the head of the precipitation boxes. This method came into general use on the Rand, South Africa, for the precipitation of the weak solutions resulting from the treatment of slime, and finally entirely superseded the electrolytic method of precipitation.

Julian and Smart[3] state that the general method of preparing the zinc-lead couple is to immerse the zinc shavings in a 1 to 5% solution of lead acetate prior to packing them in the precipitation boxes. Carter[4] calls attention to the importance of the proper preliminary preparation of the zinc for this method of precipitation. He suggests[5] stirring the freshly cut zinc shavings in a 10% solution of lead acetate. If the shavings are not thoroughly stirred in the solution, only the outside of the mass becomes properly coated with lead. After preparation the shavings should be placed in the precipitation box at once, as exposure to the air results in rapid oxidation of the zinc. Another less favored method is to introduce a drip of lead acetate solution at the head of the precipitation boxes. According to Johnson,[6] the drip of strong cyanide solution is not generally found necessary in present-day practice.

Sharwood[7] states that the presence of 2 to 3% of lead in the zinc dust to be used for precipitation is an advantage. Clark and Sharwood[8] state that it is the general practice at the Homestake to maintain a drip of lead nitrate solution at the feed pipe carrying the zinc emulsion, but that this can be dispensed with when the silver content of the solution is above normal. (In this case a gold solution is precipitated.)

In use, the zinc-lead couple gradually becomes less and less active until a point is reached where it no longer properly performs the function of precipitation. This makes necessary more frequent clean-ups and the destruction of a greater proportion of zinc by acid than where the couple is not used. After a short time, the head compartments of the precipitation boxes begin to precipitate less, and this goes on until, after about ten days, the zinc in the head compartments becomes dead and rises to the surface of the solution. The longest period recorded by Carter[9] for running a precipitation box, using the zinc-lead couple, with continued good results without cleaning up, was twenty-two days. It has been suggested that this difficulty might be overcome by using the inactive zinc from the slime precipitation boxes for precipitating the stronger solutions, as, for example, where a sand plant was also operated. At present, in South Africa, according to Johnson,[10] the interval between cleaning the precipitation boxes is seven days. In large plants, the clean-up takes place three times per month.

Résumé

1. The zinc-lead couple is of particular value in precipitating solutions containing copper or gold solutions containing a low percentage of cyanide.

2. In the majority of cases where the solution contains an appreciable amount of silver, the lead couple is unnecessary, although the presence of a small percentage (2 to 3%) of lead in the zinc dust, if this method of precipitation is used, is generally favored by most operators. The most of the commercial sheet zinc from which zinc shavings are cut contains upward of 1% of lead, so that, to a greater or less extent, the zinc-lead couple is involved in all systems of zinc precipitation.

3. For forming the zinc-lead couple, it is necessary to use a soluble lead salt. Most generally the acetate has been used for this purpose on account of being the most readily available commercial salt, but the nitrate has

been used at times on account of its higher lead content.

4. The zinc-lead couple necessitates the frequent removal of the inactive precipitant, which is a decided disadvantage, even when used for precipitating stronger solutions, for inevitably some oxidation takes place in handling the decomposed zinc. On account of the constant addition of fresh precipitant and the comparatively small excess of precipitant remaining in the precipitation press, zinc dust precipitation seems to more readily lend itself to precipitating coppery solutions or for the use, in general, of the zinc-lead couple.

Lead Salts and Extraction

In 1893, MacArthur and Ellis[11] were granted a patent for the use of lead, plumbate, carbonate, acetate, and sulphate, mercuric chloride, sulphate or chloride of manganese, ferric hydroxide or oxide, as well as various zincates and other oxides, in connection with cyanide solutions. They mention the compounds of lead and mercury as being especially effective in increasing the extraction of the precious metals. It is evident, from their specification, that they considered the sole function of these compounds to be that of removing soluble sulphides from the solution.

Despite the fact that Clennell,[12] Hamilton,[13] Clevenger,[14] and others[15] have shown that soluble sulphides do not exist in mill solutions, especially when zinc precipitation is used, at the time that they come in contact with a fresh charge of ore, there are still those who adhere to the idea that the principal function of lead salts in cyanidation is to remove soluble sulphides from the solution. While it is true that lead salts will remove soluble sulphides from cyanide solutions, yet the fact that, only in exceptional cases, do such solutions contain soluble sulphides renders the addition of lead salts for this purpose superfluous. The futility of adding a remedy for a condition which does not exist does not require further comment. The absence of soluble sulphides in mill solutions is readily understandable when it is considered that there are at least three reactions which prevent their accumulation in the solution, if indeed not their actual formation, except perhaps momentarily: (1) zinc taken into solution during precipitation appears to be as effective for their removal as lead salts added intentionally; (2) sulphides rapidly form sulphocyanates with the simple alkaline cyanides which are always present; (3) alkaline sulphides rapidly oxidize to thiosulphates, which in turn probably largely oxidize to sulphates which cannot rise above a small percentage on account of the slight solubility of calcium sulphate. To illustrate the instability of soluble sulphides in cyanide solutions, attention is called to an extreme case recorded by Hamilton[16] where sodium sulphide in considerable amount was added to a cyanide solution for the purpose of another experiment. This solution gave a distinct brown coloration when a solution of lead acetate was added, indicating the presence of soluble sulphides. Merely decanting the solution from one tank to another caused this reaction to disappear.

Holt[17] has shown that the presence of the proper proportion of a lead salt greatly accelerates the solution of silver sulphide in cyanide solutions, but that the lead salts retard the solution of the antimonial compounds of silver. My own experience with lead salts in the cyanidation of silver-gold ores in which silver predominated, has shown that, even in cases where there was no gain in extraction through the use of lead salts, there might be a distinct saving in the time necessary to effect the maximum economical extraction. Curve No. 4 in the experimental part of this paper will illustrate this point.

At the Montana-Tonopah mill,[18] Tonopah, Nevada, a saving in cyanide is noted when lead acetate is used. At the West End mill,[19] Tonopah, Nevada, it has been noted that the solution showed more sulphocyanate when lead acetate was not used. Mr. von Bernewitz[20] makes the general statement that lead salts retard the formation of sulphocyanate. The following reactions given by Kühn[21] show the possible formation of elemental sulphur in a cyanide solution when treating a sulphide ore through reactions which may take place with alkaline sulphide formed during the solution of silver sulphide:

$$Na_2S + Ca(OH)_2 = CaS + 2NaOH$$
$$2CaS + 2H_2O = Ca(SH)_2 + Ca(OH)_2$$
$$Ca(SH)_2 + 2O_2 = CaS_2O_3 + H_2O$$
$$CaS_2O_3 = CaSO_3 + S$$
$$CaSO_3 + O = CaSO_4$$

An anonymous[22] discussion of Clennell's paper upon 'Lead Salts in Cyanide Treatment' calls attention to a special case where, when lead salts were not used, large amounts of free sulphur formed in the solution, which interfered with extraction. Megraw[23] also records the same condition as occurring in treating a silver ore when lead acetate was not used; elemental sulphur separated out and poor extractions and a heavy consumption of

cyanide resulted. High cyanide consumption resulting from elemental sulphur is readily understood when it is known that elemental sulphur forms, with solutions of the alkaline cyanides, sulphocyanate. In the one case of the treatment of a silver-gold ore where I have had an opportunity of making a complete investigation of this subject, I found that the use of lead acetate resulted in a lessened cyanide consumption. It is impossible to say just how generally the statement that lead salts retard sulphocyanate formation and thereby diminish cyanide consumption holds true, but that it does, in certain cases, there is quite conclusive evidence.

Hamilton[24] is of the opinion that the advantages of lead acetate have been considerably over-rated. In some cases he has noted a slight gain in silver extraction, which is counteracted by a loss in gold extraction. He considers lead acetate to be of particular value in starting a new plant when there is no zinc in solution. At the Tonopah Belmont mill,[25] a 3 to 5% better extraction of the silver is realized when lead acetate is used. At the MacNamara and West End mills,[26] in the same district, no benefit to extraction is noted. In Western Australia[27] lead salts are especially useful in treating the telluride gold ores when there has been a bad roast. In treating the telluride gold ores of the Cripple Creek district, Colorado, lead salts are said to be of no benefit. Mr. von Bernewitz[28] is at a loss to account for this difference in behavior, but it is possibly due to the fact that Cripple Creek ores contain a small percentage of lead while, so far as I am aware, the ores from Western Australia do not. Lindgren and Ransome[29] state that galena in small quantities, although not always perceptible to the naked eye, is probably almost universally distributed in Cripple Creek ores. Crowe[30] states that a streak of galena is invariably to be observed upon the tables when concentrating Cripple Creek ores.

Clennell[31] has shown, in the case of a Mexican silver-gold ore, that, when copper was added to the solutions, extractions were better when lead salts were used. My results which follow in the experimental part of this paper, show very conclusively the effect lead salts may have in decomposing copper-silver minerals.

Clennell[32] has shown that almost any lead compound, either soluble or insoluble, may be used, except certain of the salts of the organic acids or possibly salts in which the lead is combined in the acid radical of the salt. He also shows the rather surprising fact that finely ground galena may be effective for this purpose. A possible explanation for this is Caldecott's[33] contention that the action of the lead salt is cyclic and that a small amount is as effective as a large amount on this account. Thus a small amount of lead passes successively through the stages of oxide and sulphide according to the following equations:

$$Na_2S + PbO = PbS + Na_2O$$
$$PbS + NaCN + O = NaCNS + PbO$$

Frequently, as has already been pointed out, the formation of sulphocyanate is decreased by the addition of a lead salt, so that this is only partly true.

As early as eight years ago, I[34] emphasized the importance of using the correct proportion of the lead salt. Since that time, Clennell[35] has also called attention to the same point. At the Tonopah Belmont mill,[36] Tonopah, Nevada, they use between 0.4 and 1 lb. of lead acetate per ton of ore. Between these limits there is little change noted in extraction. It has been proved at this plant by actual mill experience that too much lead salt gives no better results than none at all. The amount used is governed by the proportion of zinc in solution; when the zinc rises above 0.05%, the proportion of lead acetate is reduced. The effect of using too great a proportion of lead acetate was illustrated at this plant by the case of a slime charge where both shifts had added lead acetate by mistake. Only 50% extraction was indicated upon this charge, but when the charge was divided and one-half new material added, an 80% extraction was realized. The importance of using the proper proportion of lead salt is also shown in the experimental part of this paper.

Clennell[37] states that an excess of lead in a soluble form in an ore may exert a harmful influence upon cyanide treatment. He[38] also states that the alkaline carbonates or bicarbonates precipitate lead from cyanide solutions without precipitating gold or silver. This would seem to indicate a method of overcoming this difficulty should it ever arise.

Experimental Investigation

In 1908, I had the opportunity of investigating the effect of a lead salt upon the cyanidation of a certain Central American silver-gold ore, where the beneficial effect arising from its use had been confirmed by several operators and was, therefore, unmistakable. The investigation was carried on at the mine and comprised many small scale tests, as well as large scale tests in the mill upon the regular slime charges.

Character of Ore.—The ore treated had a gangue consisting largely of quartz, clay, and calcite, with a small amount of manganese minerals and pyrite. One prop-

erty, from which ore was not mined at this time, but which has since become a producer, contained considerable manganese. Silver occurred largely as the sulphide (argentite) and more rarely as the haloid minerals. Finely divided native silver was also at times observed. There may have been other silver minerals present, but their identification was difficult, if not impossible, on

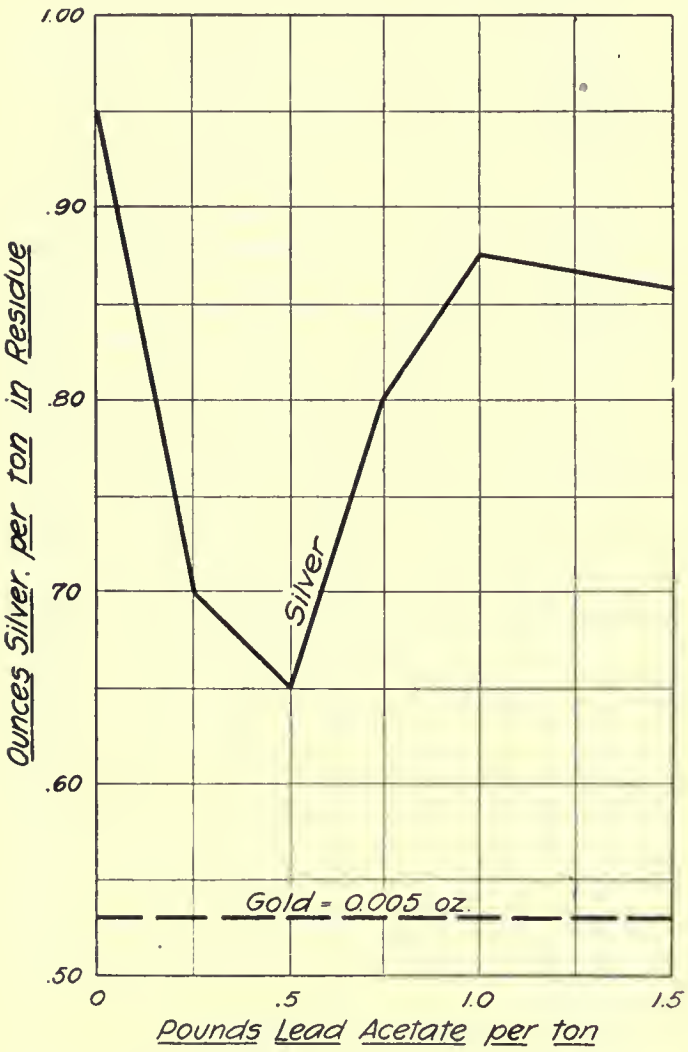

FIG. 1. EFFECT OF LEAD ACETATE UPON THE SOLUTION OF GOLD AND SILVER IN SLIME CHARGE, NO. 1160.

account of being finely disseminated, if they occurred at all. Gold occurred native in a finely divided state and also probably intimately associated with certain of the other minerals. Copper was present in a very small percentage, scarcely more than a trace; under ordinary conditions not enough to affect cyanide treatment in the slightest degree, but, as will be pointed out later, this small amount of copper had an important influence upon the solution of a portion of the silver. Although arsenic and antimony were especially looked for upon several occasions, they were never detected in more than traces in the ore, solutions, or precipitate. It is well, however, to bear in mind that these elements could be combined with a part of the silver and still escape detection on account of the minute quantities which would be involved. Evidence of selenium was noted when melting the precipitate by the characteristic rose colored sublimate which condensed upon the cooler parts of the melting furnace. The ratio of silver to gold varied somewhat, but, at this time, the average was not far from fifty parts of silver to one part of gold. The average value of the ore was about $8 per ton of 2000 pounds.

System of Milling.—Briefly, the system of milling employed was to crush the ore in cyanide solution by stamps and a closed circuit of classifiers and tube-mills to approximately 100 mesh. The total product was treated by agitation in mechanical agitators, followed by filtration in a Butters filter. Later the practice was varied to the extent of crushing to approximately 80 mesh, separating the leachable sands and treating them by percolation. Treatment of the slime portion was continued by the same method as formerly used for the total mill product. As the acetate was the particular lead salt which had been previously used in the plant, it was used throughout this investigation. The small scale tests were made upon slime pulp removed from the agitators at the end of collection and after agitation had commenced, so that a uniform sample would result. As the crushing was in cyanide solution, a considerable extraction had been made at this stage. A moisture determination was made upon the pulp and from this was calculated the volume to give in each case 100 grams of dry slime. The dilution, lime content, and other factors were the same as the large charge undergoing treatment in the plant, the only variable in the small tests being the amount of lead acetate added. Open bottles agitated by a roller agitator were used in making the tests. On account of the perfect control of the various factors of treatment, the small scale tests formed a valuable guide to the making of the large scale tests in the plant. They were especially valuable in that all the samples in a series of tests could be taken from the same lot of pulp.

By making a series of tests upon several different lots of pulp, a very good general line of attack could be formulated for making the large scale tests. In every case, the small scale tests were verified by large scale tests in the plant.

The analyses of solutions given were made upon samples of solution which were all taken at the same time and when there was being used in the mill 0.5 to 0.6 lb. of lead acetate per ton of dry slime. The analysis of bullion was not made upon the bullion produced from the particular lot of precipitate of which analysis is given. Although the results are not directly comparable, they may be taken as being typical.

Effect of Lead Acetate Upon Slime Charge No. 1160. —Solution from pulp after adding cyanide, titrated: cyanide 0.091%, alkali 0.077%, dilution 3.76 to 1. Assay of pulp at beginning of treatment after washing with water: silver 2.96 oz., gold 0.03 oz. A considerable extraction had been made during milling.

All factors were the same in this series of tests, except the proportion of lead acetate added. The lead acetate used contained 54.3% metallic lead.

No.	Lead acetate per ton dry slime, lb.	Cyanide in solution, %.	Alkali, %.	Assay of residue: Ag, oz.	Au, oz.
1	none	0.052	0.091	0.95	0.005
2	¼	0.081	0.083	0.70	0.005
3	½	0.076	0.078	0.65	0.005
4	¾	0.068	0.085	0.80	0.005
5	1	0.057	0.090	0.88	0.005

Inspection of the extraction curve, Fig. 1, shows in a most unmistakable manner the beneficial effect upon the silver extraction of the proper proportion of lead acetate and the lack of advantage of more than this correct proportion. The extraction of the gold is unaffected throughout this series. The large apparent saving of cyanide with the addition of a small amount of lead acetate, together with the rapid falling off as the proportion of lead acetate increases, is interesting, but gives a greatly exaggerated idea of the saving possible in mill practice. The titrations for free cyanide were made as carefully as possible with standard silver nitrate solution without the use of an indicator, but the determination of free available cyanide in solutions containing zinc is at best only an approximation.

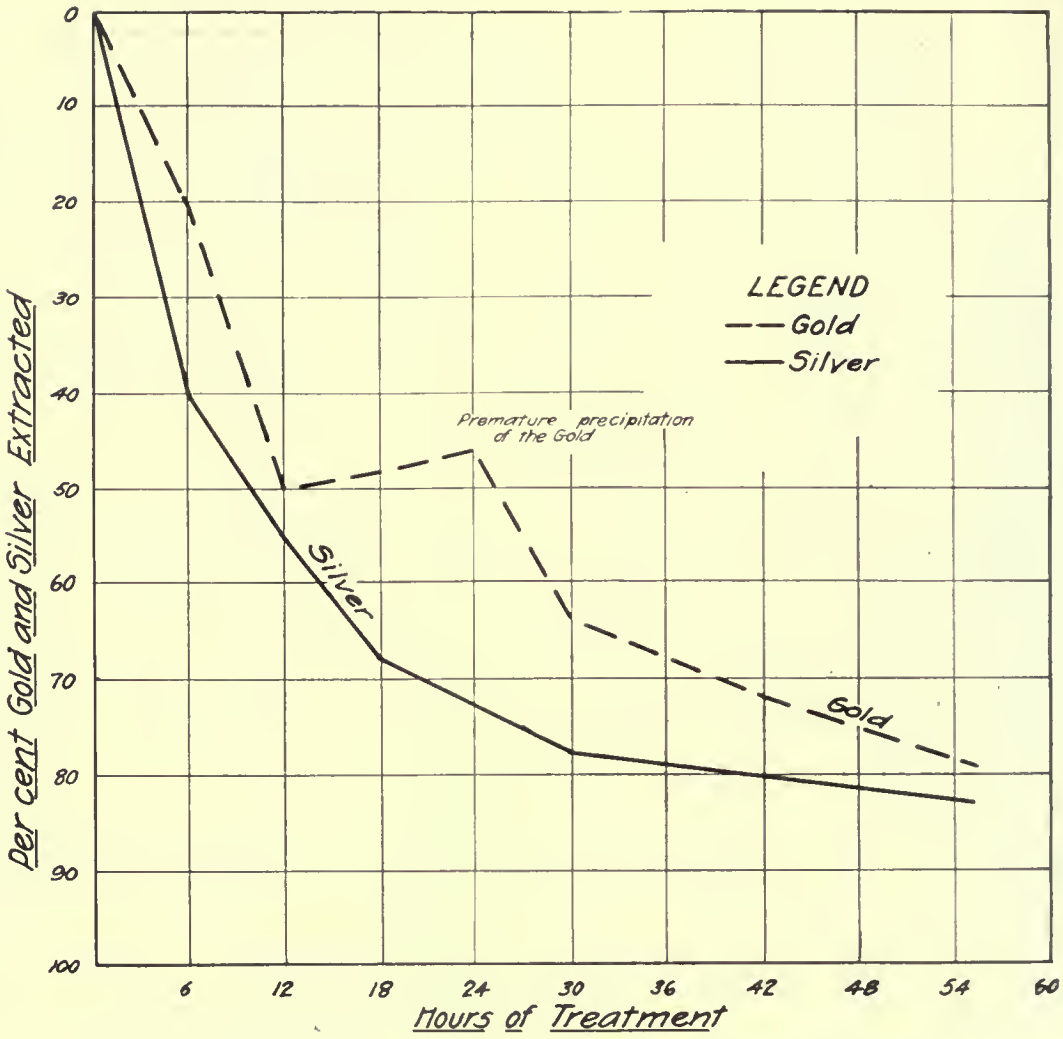

FIG. 3. AVERAGE EXTRACTION CURVES FOR GOLD AND SILVER OF THREE SLIME CHARGES.

Effect of Lead Acetate Upon Slime Charge No. 1330.—After the series of tests upon slime charge No. 1160, and several others similar to it, had been made, it was accidentally discovered that, in all cases where there was a gain in the silver taken into solution, or in other words an increase in the silver extraction, there was also a gain in the copper taken into solution. When lead acetate was not used, there was apparently no copper taken into solution, when mill solution was used in making the tests. It must be remembered that the amount of copper involved is very small; in the one case critically investigated it was not in general as great as the additional silver taken into solution. The general conditions were the same as with slime charge No. 1160. (For analyses, see p. 641.)

The accompanying extraction curves, Fig. 2, for slime charge No. 1330 show a very noticeable improvement in both the silver and gold extraction up to 0.5 lb. per ton of lead acetate. At 1 lb. the extraction of both is the same as when none is used. The fact that the maximum gold extraction occurs at 0.5 lb. per ton, the same proportion which gives the best result with silver, would seem to indicate that at times the last of the gold was very intimately associated with the refractory silver. The proportion of copper taken into solution is somewhat irregular, but, in general, increases as the proportion of lead acetate added increases.

This test seems to indicate that the small amount of copper occurring in this ore is in combination with a portion of the silver in the form of a definite mineral. Dana[39] describes the mineral stromeyerite, for which the formula $(AgCu)_2S$ or $Ag_2S{\cdot}Cu_2S$ is given. Although specimens of this mineral could not be isolated from the ore and identified on account of the minute quantity involved, yet all the evidence indicates that, in this case, the additional silver dissolved, as a result of the use of lead acetate, probably occurred in this combination. As this mineral occurs in various parts of the world, it is a factor not to be neglected in the cyanidation of silver ores.

In Fig. 3 are shown characteristic gold and silver extraction curves. These curves are an average of three curves plotted from the results obtained from the treatment of three separate slime charges. The symmetrical form of the silver extraction curve will be noted, as well as the irregular form of the gold extraction curve. In the case of the gold, very well defined premature pre-

[39] 'A System of Mineralogy,' J. D. Dana and E. S. Dana, 6th Ed., New York, 1904, p. 56.

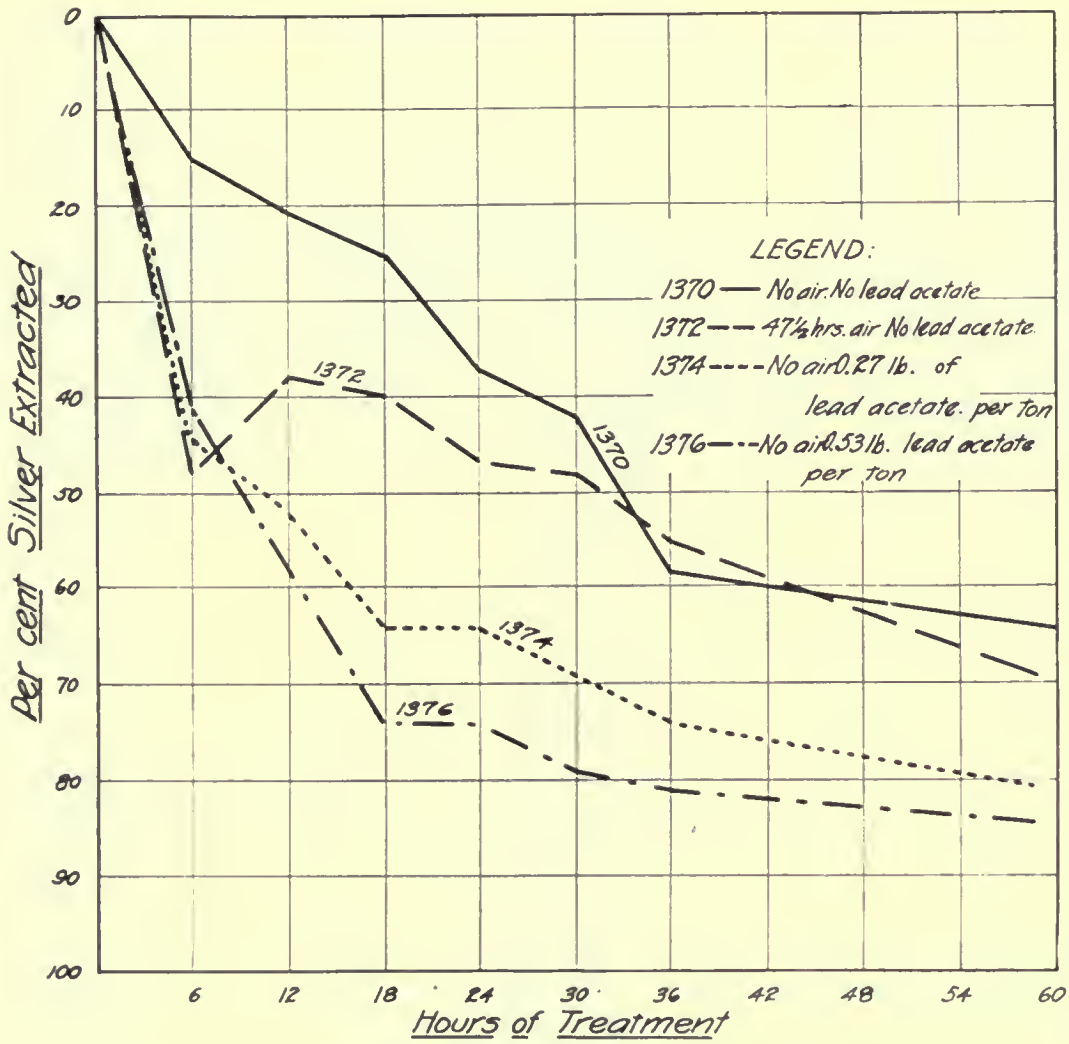

FIG. 4. EFFECT OF LEAD ACETATE AND AIR UPON THE SILVER EXTRACTION OF FOUR SLIME CHARGES.

cipitation took place between 18 and 24 hours after agitation began. As the treatment proceeds, the gold extraction becomes normal.

Fig. 4 shows the silver extraction curves for four separate slime charges treated as follows: Agitated mechanically without the addition of air or lead acetate; agitated mechanically and with 47½ hours of air; agitated mechanically and lead acetate added at the rate of 0.27 lb. per ton of dry slime; agitated mechanically and lead acetate added at the rate of 0.53 lb. per ton of dry slime. The charge with which the air was used shows an acceleration of the silver extraction at the end of 6 hours, but at the end of 12 hours a noticeable premature precipitation of the silver has taken place. At 35 hours the extraction is the same as when no air was used. At the end of 60 hours the extraction is 6% higher than when no air was used. The addition of 0.27 lb. of lead acetate has the effect of making the extraction curve more regular and of giving a considerably higher ultimate extraction at the end of 60 hours. The addition of 0.53 lb. of lead acetate shows a better extraction from 9 hours on than when 0.27 lb. is used. This curve more nearly assumes the ideal form.

Fig. 5 shows the gold extraction curves for the same four slime charges of which the silver extraction curves are shown in Fig. 4. Definite evidence of premature precipitation is only shown in the two cases where lead acetate was not used. These curves are erratic. However, it is worthy of note that after 60 hours there is not a great deal of difference in gold extraction, the higher proportion of lead acetate showing rather the poorest result of the four.

Conclusions

1. Lead salts may serve to keep down the concentration of soluble sulphides in solution, but they seldom function in this capacity for the reason that soluble sulphides are rarely present in mill solutions.

2. They may accelerate the dissolution of silver from ores in which silver occurs as sulphide, through the more prompt removal of the sulphur ion from the system.

3. They may in certain cases with sulphide ores effect

*Lead present, but not determined.

a saving of cyanide through retarding the formation of sulphocyanate or preventing the separation of elemental sulphur from the solution.

4. They may be a benefit when a portion of the silver is intimately associated with copper; also when the concentration of copper in the solution rises to a dangerous point, they may mitigate its fouling tendency. However, this statement does not mean that the use of lead salts is a universal panacea for all the ills due to copper cyanidation. So far as we know, it is only where the effect is not too great that this remedy is useful.

5. A great variety of the compounds of lead may be used for this purpose. The compound used should depend upon the cost of its lead content as well as its convenience in use. The compound most generally used in the past has been the acetate, although litharge has been claimed equally satisfactory. The cost of the lead content of litharge is perhaps lower than any of the other compounds, but it is more difficult to apply, as it is necessary to grind it very fine and exercise care to see that it is thoroughly mixed with the charges undergoing treatment. However, an excess of litharge appears to be less detrimental than an excess of a soluble salt.

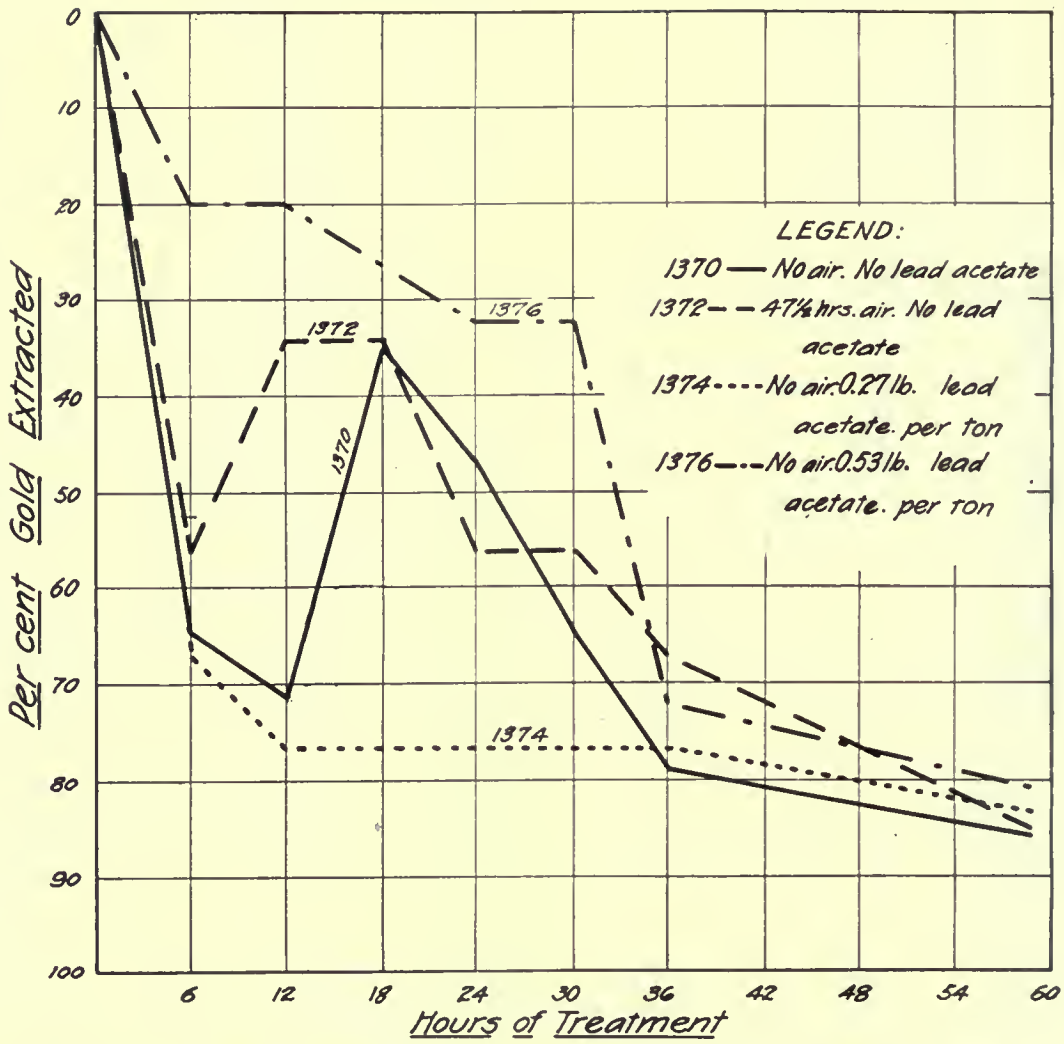

FIG. 5. EFFECT OF LEAD ACETATE AND AIR UPON THE GOLD EXTRACTION OF FOUR SLIME CHARGES.

6. Too great care cannot be exercised in adding the proper proportion of lead salt. This can only be determined by careful experimentation in each particular case, and should be checked at frequent intervals.

7. A number of those who have written upon the subject are of the opinion that lead salts may be of advantage in starting a new plant with fresh solution, but that this advantage disappears after the solutions have been in use for some time. This clearly points to the fact that there are a number of substitutes which may perform the same functions that the lead salt would. Perhaps chief among these is zinc taken into solution during precipitation. On the other hand, my own experience in at least one case, in treating a silver-gold ore was that the use of a lead salt was more advantageous with the mill solution than with fresh solution. Although there might be other factors which might enter in, the presence of copper in solution possibly explains this contradictory behavior. Small amounts of mercury escaping from amalgamation processes preceding cyanide treatment would more or less function in the same way that lead salts do. Aëration might also at times be an efficient substitute.

8. On the whole, the advantages arising from the use of a lead salt are more apparent in treating silver ores, or silver-gold ores in which silver occurs in combination with sulphur, than in treating gold ores. In ores in which the silver is combined with antimony it is likely to be a detriment. It may be said that the advantageous use of lead salts is one of the finer points of the game, and, even in cases where its use might be advantageous, unskilled application may spoil the whole effect.

PLATINUM PRODUCTION of the United States in 1913 was 482.87 oz., worth $18,477, from California and Oregon. From refining gold and copper bullion the recovery was 650 oz. Imports were valued at $5,040,210. Russia produces 250,000 oz. per year.

THICKENER TANKS

ORE-BINS BEFORE COMPLETION.

Cyanidation at Shafter, Texas

The Presidio Mining Co., operating the famous silver mine at Shafter, in western Texas, treated its ore until recently by pan-amalgamation. Last year the mill was rebuilt under the supervision of the superintendent, Edgar M. Gleim, and cyanidation adopted instead. Through the courtesy of W. S. Noyes, the manager, we are enabled to present the accompanying flow-sheet, cross-section, and description of the mill. The design of the mill is worth note, since the delay in adoption of cyanidation has enabled the Company to take full advantage of the most recent developments in the art.

The Shafter ore is a silicious limestone. The silver, which occurs mainly as the chloride and bromide (embolite), has apparently been introduced into the common limestone of the region in connection with the intrusion of basic eruptive dikes. The orebodies are large but irregular, and systematic persistent development alone has permitted the continued operation of the mine. The property was purchased in 1881 by the late General Shafter and his associates, and in 1882 turned over to California operators for development. The control of ownership has remained closely held by the few friends who early joined the enterprise.

The ore averages in value about 18 oz. per ton. One analysis shows: silica, 61.8%; lime, 11.8; iron, 4.5; magnesium, 2.4; zinc, 2.4; manganese, 0.4; lead, 0.5; sulphur, 0.2; carbon dioxide, 13.2; undetermined 2.8; and silver, 20 oz. In part it is soft and talcy, and in part extremely hard. The mill is now treating between 130 and 140 tons per day, the total for July 1914 being 3782 tons. Ore from the mine is crushed and transported to the mill ore-bin by an aerial tramway having a track rope of 1⅛ in. diameter for loaded skips and ⅞ in. for 'empties,' and a traction rope of ⅝-in. diameter.

Challenge feeders supply ore to three batteries of five stamps each. There are five driven by one, and ten by another cam-shaft, at 108 drops per minute, crushing about 8.4 tons per stamp-day each. Consumption of steel in shoes and dies is 1.18 lb. per ton crushed. The counter-shaft driving the cam-shafts runs at 106 r.p.m. and has driving wheels 14 by 35 in., bull-wheels on the cam-shafts being 16 by 69 in. The ratio of cyanide solution to ore in the mortars is 7 to 1, and 29% of the silver is dissolved at this point.

Three sizes of screens are used at times, and the following grading tests are average samples of battery pulp:

	20-mesh.	10-mesh.	4-mesh.
Size of opening, inches	0.027	0.094	0.125
Size of wire, inches	....	0.062	0.094
+40 per cent	23.50	33.50	51.00
+60 per cent	10.05	8.40	7.10
+80 per cent	7.10	7.50	4.50
+100 per cent	10.80	8.50	6.40
+150 per cent	8.30	3.30	5.50
+200 per cent	6.07	5.00	3.50
—200 per cent	33.20	33.40	22.00
Classification of pulp:			
Sand, per cent	65.82	66.20	78.00
Slime, per cent	33.20	33.40	22.00

Pulp from the batteries flows to two screw classifiers working at 13.3 r.p.m., discharging the coarse material through 9-in. screw conveyors at the end of these classifiers to two 4½ by 18-ft. tube-mills, running at 28.8 r.p.m. The usual closed-circuit system is observed. Feed and discharge of the mills is as follows:

Screen. Per cent.	Feed.	Discharge.	Final product.
+ 40	56.00	1.70	...
+ 60	9.50	1.20	0.10
+ 80	8.00	2.50	0.80
+100	13.50	9.10	1.60
+150	7.00	11.70	8.30
+200	2.00	23.60	10.30
—200	4.00	51.10	80.60

Pebble consumption is 3.4 lb. per ton of ore milled. There is 16.6% of the silver dissolved in the mills.

Slime from the classifiers is lifted by bucket elevators to a 5-ft. diaphragm cone classifier and then to a Dorr 10 by 30-ft. thickener. The elevators consist of 12-in.

CROSS-SECTION OF MILL.

by 8-ply belts with 6 by 11-in. buckets, traveling at 298 ft. per minute.

Thickened slime flows to four 14 by 28-ft. conical-bottom Pachuca tanks in series. By the time this is in agitation in No. 1 tank a total of 75% of the silver has been dissolved, so that only 13.8% is further recovered by agitation. Average specific gravity of the slime is 1.31 or 38.45% dry ore. Strength of solution is maintained at 2 lb. sodium cyanide per ton of solution, consumption being 0.9 lb. per ton of ore treated. Lime is 11.13 lb. per ton.

From No. 4 Pachuca the slime goes to another 10 by 30-ft. Dorr thickener, which is used as a dilnter to lower the value of solution going to the filter, an 11½ by 14-ft. Oliver. Vacuum is maintained by a 10 by 14-in. Oliver dry pump. Residue is neutralized with ferrous sulphate, and then flows to a pond.

Silver-bearing solutions are clarified in two 4 by 16-ft. tanks, and then pass through one 6 and three 5-compartment double 30 by 30-in. zinc-boxes. The clean-up room contains a 5 by 5-ft. clean-up tank, precipitate drier, and No. 275 Donaldson tilting furnace. An average month's run results in over 5000 tons of solution flowing through the zinc shaving. Solution heads assay 3.29 oz. and tailing 0.35 oz. per ton, 1.4 lb. of zinc being consumed per ton of ore milled. Precipitate averages about 30% silver, and, in melting, about 25% borax glass and 11% bicarbonate of soda are used as fluxes.

A feature of the Presidio mill is the power plant, which consists of one 100-hp. and one 150-hp. De la Vergne crude-oil engine, type FH, working at 200 and 164 r.p.m. respectively. These give great satisfaction, the running time being 100% for two months and not under 99% for a period of 5 months. The oil consumption is 0.4 lb. per brake horse-power hour.* The smaller engine drives the stamp counter-shaft by a rope drive. This rope also drives a counter-shaft in the engine-room from which the air-compressor and electric generator are driven by belts. The larger engine drives the main mill counter-shaft (which is a prolongation of the crank-shaft of the old Corliss engine), and from this shaft the tube-mills, classifiers, pumps, and filter are driven. The counter-shaft and stamp counter-shaft, before mentioned, are also belted from this shaft, and by means of suitably arranged clutches can be driven by either of the two oil-engines. As a stand-by there is a battery of 54 in. by 16-ft. boilers and a 16 by 36-in. Reynolds Corliss engine of 125 hp. The mill may be driven by this engine and by either of the oil-engines, or by the two oil-engines alone. The equipment also includes a 20-kw. General Electric generator and a 10 by 10-in. Ingersoll-Rand straight-line compressor and the usual accessories.

MILL TERMINAL OF TRAMWAY BUILT OVER THE ORE-BINS.

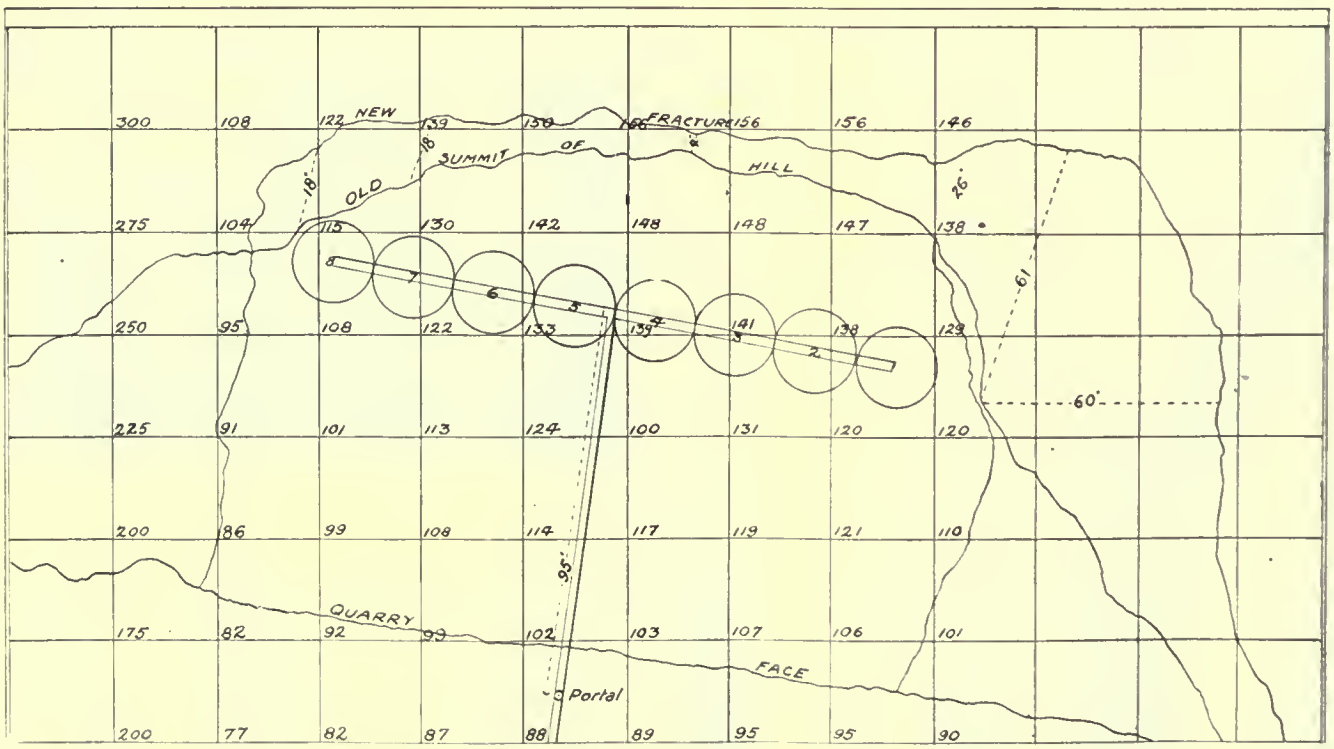
Blasting by Wholesale

By M. W. von BERNEWITZ

A large quantity of rock is quarried from various points in the north part of San Francisco bay, California. This is used for concrete construction, roads, filling for the waterfront, and other purposes, being loaded on skip and hopper barges and towed to various points as desired. For filling in part of the waterfront on the San Francisco side of the bay, and constructing part of the new two-mile mole for the Key Route electric train system on the Oakland side, the Daniel Contracting Co. is supplying about 1,000,000 tons of rock. This is excavated at the firm's quarry at McNear's point, about an hour by water from the city. Here is a fully equipped plant consisting of three Bucyrus steam-shovels, each capable of handling 1000 to 1300 cu. yd. of rock in 10 hours, a railroad system with light locomotives and side-dump cars, and electric dumping apparatus which can fill a skip barge of 250-ton capacity in about an hour. Hopper barges carry up to 900 tons each, and may be filled at a greater proportionate rate.

PART OF SAN FRANCISCO BAY. THE QUARRY DESCRIBED IS AT SAN PEDRO POINT.

In order to have plenty of rock for the shovels, large quantities of material are broken at the two faces being worked. One is a brown and the other a blue metamorphic sandstone, the latter being the hardest. On July 11, 1914, a large blast was made at the brown face, which kept the shovels supplied for over two months. As will be seen from the plan, an adit was driven into the hill 95 ft., from which cross-cuts were driven 70 ft. each way. These were only large enough to enable a machine-drill to be worked, and to wheel out the rock broken. The cross-cuts were divided into four sections each, and were charged with powder. This is received in 12.5-lb. bags, with 4 bags to a 50-lb. case, and is special powder for such large blasts. Three No. 7 electric exploders were inserted in each charge, making 24 in all. Leads to convey the electric current for exploding consisted of No. 14 insulated wire, laid in 2 by 4-in. grooved boards and connected in straight series.



PLAN SHOWING ELEVATIONS, ADITS, CROSS-CUTS, POWDER ARRANGEMENT, OLD AND NEW SUMMIT OF HILL. THE FIGURES GIVE ELEVATIONS ABOVE SEA-LEVEL.

The charges were well tamped with fine and large rock, and the adit filled to the portal. Laying the powder and tamping took about four days, and was supervised by J. C. Costello of the California Trojan Powder Co. Each section was charged with powder made by this Company, as follows:

Load.	No. 2 powder, pounds.	No. 4 powder, pounds.	Total, pounds.
1	2,250	....	2,250
2	2,300	....	2,300
3	2,500	....	2,500
4	....	2,250	2,250
5	....	2,250	2,250
6	....	1,900	1,900
7	....	1,900	1,900
8	450	1,700	2,150
Total	7,500	10,000	17,500

To help the main blast by cutting away the foot of the hill, so as to allow the broken rock to slip down, eight 22-ft. holes were bored at equal distances by a machine with 1¼-in. drills. These 'toe-blasts' were fired first, and so loosened the bottom. In setting off the large charge, a 220-volt, 110-ampere electric current was switched on to the leads. At the moment of disruption, as shown by the halftone, the whole hill was lifted out several feet, fell back, and then the broken rock started to roll down. There was only a dull thud heard, more noise being caused by rolling of rocks than the actual explosion. In the plan will be seen the old summit of the hill and new line of fracture, in one place 61 ft. apart. The blast was an excellent one, and a total of 166,250 tons of rock, well broken up and requiring no secondary blasting, has since been moved by the steam-shovels, and dumped into San Francisco bay. Each pound of powder broke 9.5 tons of rock.

In wholesale mining, where the conditions are similar, this system of blasting, known as the 'coyote,' should be satisfactory.

ACCORDING to the California State Mining Bureau, there were 182 quarries operated in 42 counties of the state in 1913, and probably an equal number were idle. The output was valued at $6,168,020, against $5,473,928 in 1912. The quantities of crushed rock were as follows:

Classification.	Tons.	Value.
Macadam	1,533,330	$ 885,638
Rubble	686,983	361,079
Concrete	931,098	607,194
Unclassified	3,268,142	1,988,876

Marin county, in which is the quarry described in the article on blasting on the preceding page, produced 421,032 tons of rubble in 1913.

Sand and gravel produced totaled 3,393,268 tons, worth $972,694; paving blocks, 6,364,000, worth $363,505; and granite for various purposes, 1,324,835 cu. ft., worth $729,277.

TIN IMPORTS into the United States last year totaled $47,295,050, or 40.8% of the world's production. The domestic output was 84 short tons of 60% ore, worth $36,970, from Buck creek, Alaska.

THE BLAST AT THE MOMENT OF DISRUPTION. ENLARGED FROM A MOVING PICTURE FILM. ROCKS CAN BE SEEN IN THE AIR.

Scientific Management in the German Industries

By H. N. STRONCK

When F. W. Taylor presented his paper, 'Shop Management,' at the June 1913 meeting of the American Society of Mechanical Engineers, it aroused much interest not alone among the industries of the United States, but also in the great industrial nations of Europe, especially Germany and France. He advocated high wages and low production costs, therefore, it is but natural that in countries where industrial competition is as keen as in Germany, engineers should become interested and investigate scientific management. Taylor's writings have been translated into many languages, and they have gained a large circulation in both Germany and France.

One of the most ardent enthusiasts over the Taylor system in France, is the distinguished engineer Henri Le Chatelier, who wrote a lengthy introduction to the French edition of Taylor's work. He deals especially with the political economy of scientific management, and has aroused wide interest. Taylor's 'Principles of Scientific Management' were translated into German by Roesler. 'Shop Management' was recently translated into German by Wallich, and this edition has gained a very wide circulation. A treatise on the practice of the Taylor system was published last February by Rudolph Seubert. This book describes the practice at the Tabor Mfg. Co., Philadelphia, including a few later developments. Herr Seubert spent several years in the United States, studying the system at various factories where it has been introduced, with the intention of introducing it in Germany.

At the joint meeting of the Vereins Deutscher Ingenieure and the A. S. M. E. at Leipsic, June 1913, James M. Dodge, of the Link Belt Co., presented a paper on 'Industrial Management.' At the same meeting, Professor Schlesinger of the Charlottenburg Technische Hochschule, Berlin, presented a paper on the same subject, analyzing German conditions and showing why this system could be successfully introduced in the German industries. A large number of magazine articles have also appeared on the subject, both by advocates for and by antagonists of the system. These writings aroused great interest and Taylor is one of the most widely known men in German engineering and industrial circles.

Many German industries have actively taken up the work of installing scientific management and efficiency methods, but none of them have the system as complete as it is at the Tabor Mfg. Co. and at the Link Belt Co., Philadelphia. A number of German engineers have come to the United States to study the practical side of the work, and American engineers have gone to Europe to aid in the introduction. German mining and metallurgical men are as much interested in this work as are the men of the manufacturing industries. The difficulty, and small headway that has been made, is due to the fact that, although they have heard of such work, very few really know what scientific management is. A lengthy paper was presented at the July annual meeting of the German Society of Miners and Metallurgists, on 'Scientific Management in the Mining and Smelting Industries,' which paper explained the principles of scientific management, analyzed the present mining situation, and showed how these principles could be applied to mining and smelting. This paper created great interest in the work, and the authors were requested to give lectures to the directors and chiefs of various concerns, analyzing more especially their particular problems. The metallurgical-chemical industries have been especially interested, and concerns of that kind were making plans to take up such work, when the war broke out, which indefinitely postponed its introduction.

Mining in Venezuela

There was considerable mineral development in 1913. Prospecting for petroleum near Lake Maracaibo was carried on with encouraging results by one American and two English companies. The copper deposits near the Aroa mines, denounced by a new company, were partly developed. The gold deposits near El Callao were worked by new companies, and give promise of adding considerably to the output from that region after the installation of machinery. The iron mines at Imataca increased their shipments in 1913, but were closed at the end of the year on account of the financial troubles of the company.—*Daily Consular Report.*

ARSENIC PRODUCTION of the United States in 1913 was 2513 tons, valued at $159,236. Imports of arsenical compounds were 4701 short tons, worth $410,446, and 99,692 lb. of 'Paris green' and 'London purple,' worth $4431. There is not much profit in the manufacture of white arsenic, smelters saving it on account of the poisonous fume which would be otherwise emitted into the atmosphere.

GOLD AND SILVER BULLION AND ORES exported from Salvador, Central America, in 1913, were valued at $1,479,805, an increase of $83,075 over 1912. The Butters Salvador Mines Co. is the principal operator. Save $100,000 of gold slime, all the bullion went to the United States.

THE PRODUCTION of carnotite-bearing ores in the United States in 1913 was a record, being 2269 short tons, containing 34.8 tons of metallic uranium, and 8.5 grams of metallic radium, worth $1,020,000.

WOLFRAM EXPORTED from the Rosario district, Argentina, to Germany, was 539 tons in 1913, compared with 637 tons in 1912.

FELDSPAR PRODUCTION of Maine in 1913 was 38,248 tons, valued at $347,499.

DISCUSSION

Readers of the MINING AND SCIENTIFIC PRESS *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Laboratory Study of Secondary Enrichment

The Editor:

Sir—An editorial under the above title appeared in the *Press* for September 19. I can find little to support the main contention of the article, that the scientists connected with our great institutions of learning are not capable of investigating the difficult subject of 'secondary enrichment,' and am loath to believe with you that our universities and colleges are employing a set of men so inferior that they are no longer fit to be leaders in scientific research. I find equal difficulty in accepting the other conclusions reached by you. The gist of the editorial, as it appears to me, may be stated as follows: (1) The study of 'secondary enrichment' has become so popular that it has degenerated into a mere scientific fad; (2) the results of this sudden "crescendo of interest" is to "incite many people to join in the chorus of repeating what is old or disproved, or by making statements which are not substantiated by valid evidences or fundamental principles"; (3) college professors are not fitted to investigate the difficult problems, and many contributions concerning this subject from college laboratories are merely "obfuscations of knowledge"; (4) to obtain results, we must employ subsidized scientists furnished with elaborate equipment.

The editorial has to do, I infer, with the chemical study of sulphide enrichment, although the laboratory study includes the microscopical investigation of ores and other phases. The determination as to whether or not there has been a flood of inaccurate and popular writing on this phase of the subject involves a review of the recent literature of the sulphide enrichment. Such a summary and review of the literature for the year 1913 appeared in the January 24, 1914, issue of your periodical. I find here 25 articles listed, of which eight present results of experimental chemical work, and three others contain general discussions of the chemical principles involved. The eight purely chemical contributions include A. D. Brokaw's (University of Chicago) work on the precipitation of gold by manganese salts, H. C. Cooke's (University of Chicago) work on the enrichment of silver ores, F. F. Grout's (University of Minnesota) work on the precipitation of 'secondary' sulphides by alkaline solutions, Palmer and Bastin's (U. S. Geological Survey) study which determined the chemical formulæ according to which certain native metals and sulphides are precipitated from sulphate solutions, A. C. Spencer's (U. S. Geological Survey) important work on chalcocite enrichment, R. G. Wells' (U. S. Geological Survey) note regarding the measurement of currents developed during the solution of sulphides, which may or may not prove to be of importance in regard to sulphide enrichment, and A. R. Whitman's (University of California) article describing his successful experiments in the solution and reprecipitation of pyrite. Of all the articles cited, there is not one which does not contain a contribution to knowledge, and while a few of the theoretical chemical discussions lack accuracy, the contributions of the same are none the less real.

During the present year only two articles of a purely chemical nature have come to my notice. One is by Stuart Croasdale,[1] who described his attempt as a metallurgist to make use of the principles of sulphide precipitation on natural minerals. His results were well worth recording. The second is by J. D. Clarke,[2] who proves the importance of colloidal dispersion and precipitation, and this is one of the important contributions to the chemistry of ore deposition.

In addition to these two contributions, George Nishahara has discussed informally certain chemical points. Surely we are not as yet prohibited from discussing informally a subject of such importance to students of ore deposits, even if we have no formal contribution to make!

In looking over the list of publications on this subject prior to 1913, I find only about fifteen papers which may be considered as formal contributions to the chemistry of the subject founded on experimental work.

I conclude therefore that there has been no flood of literature on the chemistry of sulphide enrichment; that the experimental work which has been reported has been singularly productive of knowledge. What we need is more discussion, more experimental work, and more light. Only that of value will live under the attack of critical and continued discussion.

All will admit that geologists are seldom trained chemists, and the suggestion is a sound one that geologists and chemists should coöperate for the solution of problems in ore genesis. It is absurd to intimate that we do not have chemists, especially physical chemists, in our colleges competent to do this work, or that graduate students and ambitious instructors, working in well equipped chemical laboratories of our universities, are

[1] *The Eng. and Min. Jour.*, April 11, 1914, pp. 745-749.

[2] 'A Chemical Study of the Enrichment of Copper Sulphide Ores,' *Bull.* Univ. of New Mexico, Chemical Series, Vol. I, No. 2, 1914.

not capable to carry on these investigations under the inspiration and direction of the professors of chemistry. Are we incapable of obtaining the results reached in Germany by the coöperation of professor and advanced students?

One difficulty which some geologists have encountered, who have been interested in these problems, has been that there is too little team work between the geological and chemical departments in our universities, and for this reason some of the geologists have been driven to attempt the work within their own departments. Even under these conditions the results obtained have not been without value, and certainly do not deserve to be characterized as "obfuscations of knowledge." Such coöperation is destined, I believe, to solve many of the problems. The geologist must continue the microscopic examination of ores, a study which is only beginning to be taken seriously, to find out what minerals are produced in nature's laboratory and in what sequence they are formed. He must continue to gather field data in order to find out something as to the physical conditions (depths, relation to the weathered zone, etc.) under which the precipitation of a given group of minerals takes place. The more definitely these conditions are formulated, the better the chance for the solution of the problems in the laboratory.

We cannot present all the varied problems of ore deposition to a single small group of scientists and expect a satisfactory solution of them all. Exact data, such as have been furnished by the chemists of the geophysical laboratory at Washington, are of value and to be desired, but all of the problems do not admit of exact solution, and today, for example, we need further simple experimentation to determine the effect of acid, neutral, and alkaline environment on the formation of 'secondary sulphides.'

As an example of the fact that it is impossible for any one investigator to speak the final word in regard to the subject he is investigating, I would call attention to the excellent work done by E. T. Allen[3] and his associates on the sulphides of iron, zinc, cadmium, and mercury. Here is a piece of work done with such care and skill, with every advantage of equipment, that we might expect it to be final. The fact, however, that these sulphides may be dispersed by the action of hydrogen sulphide, and subsequently be precipitated and recrystallized by the loss of hydrogen sulphide, was not recognized by these investigators. This fact opens up again the question as to genesis and temperature of formation of these minerals. It may be noted also that the recognition of the importance of this process of dispersion of sulphides by action of hydrogen sulphide was recognized by a graduate student while working in a college laboratory.

Progress in science is not to be expected by submitting all questions to a single supreme court, and accepting its decisions without verification or discussion. I believe that the paths of research are still open to the earnest student, and can never be preëmpted by a single body of scientists, however accomplished.

C. F. Tolman, Jr.

Stanford University, September 23.

[Such a vigorous protest emanating from Leland Stanford University, where C. F. Tolman, Austin F. Rogers, J. D. Clark, and other workers have made some of the most notable and valuable contributions to the exact knowledge of mineral chemistry reminds us, only in a reverse way, of the minister who preached a vigorous sermon on the sins of his congregation, with the result that after the service the men whom he particularly had in mind congratulated him on his powerful sermon, which they thought should greatly benefit those to whom it applied. It can scarcely be necessary to say that we were not referring to the notable papers which Mr. Tolman has judged worthy of discussion and abstract. Nor is it possible to twist our mild statement that few professors of geology are fitted to perform the painstaking experimental work necessary in investigating such chemical problems, into a statement that "our universities and colleges are employing a set of men so inferior that they are no longer fit to be leaders in scientific research." The college professor is perforce a sort of general practitioner, and if it chances that inclination leads him to become a specialist in some line of investigation it is only under special circumstances and somewhat to the disadvantage of the work he is paid to do, namely to teach classes of students, rather than to devote his mental energies to the direction of one or two graduate students. While agreeing in the main with what Mr. Tolman has to say, it is quite possible to use his own evidence in support of our generalizations. Thus the fact that in 1913 eight papers on the chemical study of secondary enrichment were published, while in all the preceding literature there were but fifteen, apparently indicates that there is a marked crescendo of interest in the subject, and if the tide continues to rise at the indicated rate it would seem not unreasonable to expect a flood. Mr. Tolman's instance of the work done by E. T. Allen at first seems convincing, but the force of it disappears with closer scrutiny. In the same way a well equipped party often makes its way nearly to the summit of a mountain, cutting paths and establishing camps, only to be obliged to turn back before reaching the top. With the aid of these a later expedition can easily attain the summit. It is to be expected that clear headed and keen witted geologists will often be able to utilize the elaborate chemical researches to which we referred for the brilliant solution of geological problems. What the other members of our congregation will meanwhile do must be left in the lap of the gods.—Editor.]

[3] *Am. Jour. Sci.*, Vol. 183, pp. 169-236, Vol. 184, pp. 301-396.

Gold output of British Guiana to August 31 was 37,766 oz., compared with 50,653 oz. in the same term of 1913. The diamond production was 9517 carats worth $86,185, against 4637 carats and $44,419.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PHOSPHATE DEPOSITS near Georgetown, Idaho, are estimated to contain 2,663,290,000 long tons of rock, according to the U. S. Geological Survey.

ELECTRICITY was first used in Pennsylvania anthracite coal mines in 1887. According to H. M. Warren, in a paper read before the Engineers' Society of Northeastern Pennsylvania, the total electric generating capacity and power purchased for use at the mines is 79,811 kw., or 105,400 hp. Besides this, there is 440,279 hp. produced by steam for direct use. There is 754 miles of trolley wire underground, and 951 electric locomotives, using over 60,000 hp. The other electrically operated equipment consumes 19,170 hp. for breakers and miscellaneous machinery, 23,280 hp. for electric hoists, 38,500 hp. for electrically driven pumps, 2920 hp. for coal-cutting machines, 3650 hp. for lighting, and about 100 hp. for heating. There are now five breakers equipped with individual motor drives, and others are under course of construction.

A PREMATURE EXPLOSION of a charge of powder in a drill-hole at the Nevada Consolidated company's Copper Flat mine occurred on August 4, whereby five men were killed and three seriously injured. The suspected cause was an obstruction in the hole caused by rocks caving in from surrounding walls. To prevent a recurrence of such an accident, a collapsible loading tube has been designed. When the hole is bored the required depth, 50 or 60 ft., and tools are drawn, the tube, of stitched canvas, rubber lined or coated, and six inches diameter when spread open, is lowered the full depth from a reel. The powder is then poured down, after which it is withdrawn. The tube protects the walls of the hole, and prevents rocks from falling in, also from damaging the walls by water when a tamping charge of water is poured in on top of explosives used for springing or chambering the bottom of the hole.

RICH GOLD AND SILVER ORES often contain metallics, which are collected during screening of samples for assay, and should be assayed and calculated separately from the rest of the sample. The following method is recommended by A. M. Smoot, in the *Bulletin* of the Canadian Mining Institute: Metallic scales from samples are assayed separately by the all-fire process, using 1-gram charges, and when the amount of scales is small, as many assays of each sample are made as the amount of scales will permit, but in cases where the amount of scale is large, six 1-20 assay-ton portions are used. In calculating the average assay of fines and scales, a simple method is as follows: From the assay of the scale in ounces per ton, subtract the assay of the fines in ounces per ton, and multiply the difference by the percentage of metallic scale in the sample. The result is addition of scale, that is, the amount to be added to the assay of the pulp to give the total assay of the sample. The derivation of this method is as follows:

If a = percentage of metallic scale
$100 - a$ = percentage of fines
s = assay of scale in ounces per ton
f = assay of fine in ounces per ton
x = average assay of sample in ounces per ton
$x - f$ = addition for scale.

Then $as + (100 - a)\,f = x$

$$\frac{100}{}$$

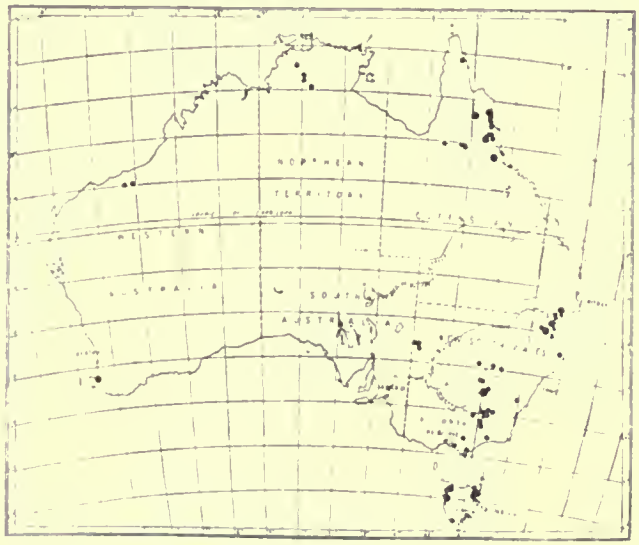
$$as = 100f - af = 100x$$

$$as - af = 100x - 100f$$

$$a\,(s - f) = x - f = \text{addition for scale.}$$

$$100$$

TIN MINING AND REDUCTION has received little attention from writers. The best known works are 'Tin Deposits,' by Sidney Fawns, and 'Metallurgy of Tin,' by Henry Louis. At the May meeting of the Australasian Institute of Mining Engineers, at Melbourne, Victoria,



MAP OF AUSTRALIA, SHOWING TIN DEPOSITS. TO THE END OF 1912 THE OUTPUT WAS 374,206 TONS, VALUED AT £30,125,571.

'Australian Tin Lodes and Tin Mills' was the subject of a lengthy paper by H. Herman, government geologist for that state. Mr. Herman has personally studied all the deposits and mills in Australia, including Tasmania. The paper was published in the *Proceedings* of the Institute, occupying 125 pages, and may be had bound separately at small cost.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

F. A. Heinze and Sundry Litigation.—The Pato Dredge's Troubles.—Copper Notes.—European Holdings in American Mining Companies' Shares.

It is hard for any topic to get much space in the newspapers these days in competition with the war news. Nevertheless, the suit of Edward Gould against F. A. Heinze, last week, was the source of a good deal of public interest. The suit was for the recovery of $1,264,449 claimed to be due on account of notes signed by Heinze as part payment in the purchase of 7000 shares of the Mercantile National Bank. The testimony involved various checks given by various people, concealed assets carried on the bank books, and the question of whether Gould had sold the stock to Heinze or to Charles W. Morse. The jury gave Gould a verdict for the full amount. Except through litigation, Heinze is no longer able to attract much attention in the mining field. He has lost control of nearly all his mining properties except the Stewart, and save for areas of land in British Columbia, probably has not very much in the way of assets left out of the $10,000,000 that he is reputed to have brought with him when he came in from the West to show the New York financiers super-modern ways of doing business. Everything with which Heinze is connected seems to be quickly plunged into litigation, and the Ontario Mining Co., and Jonathan Bourne, Jr., have filed suit against the Stewart Mining Co., claiming that it has trespassed on the Ontario and extracted ore to the value of $40,000. The ore-shoot is just on the boundary line between the properties, and there is likely to be more work for the consulting geologists. The earnings of the Stewart in the last half-year were $537,230.

A couple of years ago, one of the Chicago papers, in commenting on the failure of the 'White Socks' baseball team to achieve successive victories, epigrammatically remarked, "There is always some damn thing!" The same remark might be made of the Pato property of the Oroville Dredging Co. There were many difficulties before the dredge arrived on the ground, as is well known, and since that time the boat seems to be under the impression that it is a French submarine, for it has sunk twice. It is reported that it will be more than a month before it can be again raised and repaired so as to resume operation. In a general way, these troubles are rather characteristic of mining operations in distant countries. There are always a great many unexpected difficulties and drawbacks, and it takes a rather rich mine to pay good profits if it is a long distance from the main centres of trade.

The directors of the Amalgamated cut the quarterly dividend to one-third of what it has been, or to 50c. per share. More than a dozen of the big companies have decreased their dividends within the last quarter, and one of the financial journals has figured out that the decreased earnings correspond to a decrease in the book value of the stocks of over $7,000,000. It is quite likely that a further cut in production will have to be made. *The Boston News Bureau* has calculated that copper stocks, which on July 1 were about 106,000,000 lb., have increased to 220,000,000 lb., or the largest surplus on hand for many years. Exports of copper continue at about two-thirds of what they were last year, and the price seems to be barely holding its own, or slowly weakening, so that the best thing that could be done would be for some more of the companies that are not making any profit to shut down until consumption can catch up to the stocks of copper. There are a great many mines which, if working at their full capacity, would make a profit on their present prices, but which on the present basis of half capacity, must be making little or no money, and it would be better for such mines to shut down now rather than to keep going for a while, with the result that not only they, but other companies, may be eventually compelled to shut down.

One of the interesting points raised by the war is the amount of stocks that will probably be thrown back on this country when the exchanges resume regular business. After the war is over, the European countries will have large war debts; they will naturally attempt to place these with their own people, and the natural supposition is that shareholdings in American corporations will be liquidated in order to place the money in war bonds that will probably have preferential treatment. *The Wall Street Journal* has been carrying on investigation of the amounts of stock held in Europe of several American corporations. Of the mining companies reported, European holdings are surprisingly small. Of the more than 7,000,000 shares of Inspiration Consolidated Copper Co., less than 1000 shares are held in Europe, and of the Greene Cananea Copper Co., Europe holds less than $55,000 out of $48,614,700. Of the Batopilas Mining Co., less than 6000 shares out of 446,599 outstanding are held in Europe, while of the Horn Silver Mining Co., less than 70,000 ont of a total of 400,000 are held there. If the same ratio holds true for most of the other mining corporations, it does not seem probable that the mining-share market will be heavily affected by European selling after the war is over.

WASHINGTON, D. C.

No More Mining Legislation this Session.—Assessment Work Bill Failed to Pass.—Mining Representative for Trades Commission.

The adjournment of Congress now seems in sight, but there is to be no further mining legislation, not even on the proposal to enact a commission to codify the mining laws, which has been asked for by mining men. This is to be held over for the next session, when action seems sure. Congress will then be more liberal on appropriations, extravagant though it has already been, as charged. Other mining legislation is also hoped for then.

An attempt was made this week to procure action on the bills in Congress giving authority temporarily to suspend the requirement of $100 labor on all mining claims, but Congress was not very enthusiastic over the proposal as a help in the emergencies occasioned by the European war. Senator Shafroth has been busiest on this score in behalf of radium mining, and he was ready to make an appeal before the Committee on Mines and Mining of the Senate, but a quorum of the committee did not develop, and so the matter was off.

Franklin K. Lane, Secretary of the Department of the Interior, has taken a positive stand against the suspension bill. He has written a letter on the question to Congressman Foster, chairman of the House mining committee, in which he says: "I have made an investigation and found strong protest against the adoption of the policy, because many miners had already done their work, and the passage of such a bill would

be in the nature of a preference to those who had waited until the last of the year to comply with the provisions of the law. I found also that many men in mining states expected during the fall and winter to do this assessment work for others, and that the postponement of it would be in effect the shutting down of an industry." The Secretary said he had been informed that none wanted suspension work in Alaska. It is thought that this opposition will suffice to kill the bill.

The President is determined to appoint the Trades Commission in December, and he is now 'weighing' names, so that if the mining world is desirous of being represented on the Commission, it behooves it to become active. However, care should be taken here, as the President is easily offended by any 'booming' for any man. Such efforts would be fatal to the chances of any such candidate. It is better to conduct a canvass in a quiet way, by indirection. Forward in the mention for a place on this most important commission is that of James F. Callbreath, secretary of the American Mining Congress. Others proposed are E. W. Parker and Hennen Jennings.

SILVER CITY, NEW MEXICO

PHELPS, DODGE & CO. PROFIT-SHARING PLAN.—CHINO PRODUCTION.—PINOS ALTOS HIGH-GRADE ORE.—OPERATIONS IN SIERRA COUNTY.—MOLYBDENITE SHIPMENTS FROM LAS VEGAS.

The Burro Mountain Copper Co., operating the 'porphyry' copper mines at Tyrone, has started a 'profit-sharing plan' among the patrons of the Phelps-Dodge store, who are also employees of the Company, that is attracting considerable attention. The system is also in vogue at the firm's Arizona properties. The Company will share with the employees who have been in continuous employ for three months or more, the net profit accruing from sale of merchandise to them.

FIFTY-TON EXPERIMENTAL MILL AT THE BURRO MOUNTAIN MINE, TYRONE.

The extent to which employees of the Burro Mountain company will participate in this net profit, will be equivalent to 5% on their purchases of merchandise, not including wines and liquors. The year will be divided into quarterly periods to expedite the disbursal of the dividends. The new arrangement went into effect on October 1. It is an endeavor to relieve present unusual conditions, owing to readjustment of wages made necessary because of the state of the copper business, and will continue in effect as long as, in the opinion of the directors of the Company, it is advisable. There is a large force of men employed at the experimental mill of the Burro Mountain mine, and a crew at work breaking down ore for experimental work and sampling the Chemung dumps. Three churn-drills are at work prospecting new ground, and the installation of Diesel engines is under way at the new power plant. Practically all the development work of the Company was stopped at the beginning of the European crisis. This leaves about 300 men at Tyrone and Leopold, at which places Phelps, Dodge & Co. has stores.

The Chino Copper Co. is operating one steam-shovel and two locomotives at its mines at Santa Rita, as a night shift, and it is believed more additions to this shift will be made soon. The day shift is employed six days out of the week. The Chino production of copper for August was 3,045,045 pounds.

The C. & O. Mining & Milling Co., at Pinos Altos, continues to mine high-grade gold ore from the Langston vein. According to the management an ore-shoot from 1 to 2 ft. wide has been opened at a depth of 200 ft., on the incline. Ore occurs as a true fissure filling, with a granite foot-wall and a diorite hanging wall. The rich ore does not occur in pockets, as many think, but is continuous. It is sent to Silver City banks and will later go to some refinery. Ore is carefully sorted and lower grade is shipped to the Douglas, Arizona, smelter, bringing returns of from $22,000 to $24,000 per car. The ore is the richest in appearance ever taken from the famous Pinos Altos district, and is attracting great attention. Several arrests have been made for alleged high-grading. Cases will go before the grand jury in Silver City next February. In the same area, but at the extreme north end, J. T. Janes and associates have opened high-grade silver and copper ore in the Hardscrabble mine, on which a lease and bond is held. Ore assays 30% copper and 56 oz. silver per ton. A large amount of development work had been performed prior to this discovery. The vein is in soft ground and considerable timbering is necessary. Ore shipments will be made soon. George Brown, lessee of the Manhattan mine, is shipping pyrite containing good gold content. Pinos Altos in general is very active.

Las Animas Peaks Gold Mines Co., with main offices in Dallas, Texas, has taken over the group of seven claims near Hillsboro, Sierra county, formerly owned by the Hillsboro Consolidated Mines Co. It is the intention of the Company to begin systematic operations as soon as the disturbed financial condition is better. The Hillsboro, Lake Valley, and Kingston areas still present many opportunities to men with the brains and means to make profitable mines.

Margarito Romero, operator of the molybdenum mines and mill near Las Vegas, San Miguel county, has received an order for one ton of molybdenite delivered in Philadelphia. There is a great demand for this mineral from New Mexico.

The Silver Queen mine at Red River, Taos county, is shipping ore to a mill. Tables for concentration are being installed. The product will be shipped to Pueblo, Colorado, smelters. Road improvement up Bitter creek is under way.

LONDON

THE DETINNING INDUSTRY OF ENGLAND, A GERMAN PLANT IN LONDON AND THE PROCESS USED.

In recent letters I have referred to the effect of the war on the lead, zinc, and tin industries of Great Britain, and told how the previously smooth metallurgical relations between this country and the Continent have been upset. An equally interesting case, though of relatively less importance, is presented by the position of the detinning industry in the east end of London, controlled by the Goldschmidts of Essen. We are fond, politically, of talking about the 'German lie factories,' but I am sorry to say that perversions of the truth are not unknown in London. A rumor was spread freely in the city to the effect that the London Electron Works Co., which is a Goldschmidt subsidiary, had been closed on the outbreak of the war, the staff returning to Germany, leaving

a truculent German of anti-English sentiments, though naturalized here, as a sort of garrison to protect the works against a supposed attack organized by rivals or others desirous of capturing the business. Some doubt being cast on this story, I determined to go down and make inquiries. In view of the statement about truculent defenders, I was not quite sure of the nature of my reception; so as I walked from Commercial road to Limehouse basin I ronsed my courage by singing 'It's a long way to Tipperary.' I found, however, that the works were in full blast, and that those in authority, though of foreign birth, were charming men, as scientists and metallurgists should be, whatever their nationality. I ascertained that the only grain of truth in the rumor was that on the outbreak of the war, operations had to be suspended because the product of the works could not be shipped to Essen. In a fortnight or so the managers were able to modify the process and find an outlet for the products in Great Britain, so a resumption was possible after only a short interval. As the nature of this business is little known, it will be of interest to your readers if I say something of it. The London Electron company was started a dozen years ago to work E. M. Kardos' process whereby tin cans collected by the municipal dustmen, and also accumulated by the wholesale confectioners and sweetmeat manufacturers, were submitted first to cleansing operations for the removal of the clinging animal and vegetable matter; second to a baling process, whereby they were compressed into briquettes; third, to the action of heat to remove solder, paper, varnish, paint, or rubber; and lastly, to electrolysis in a caustic-soda solution, whereby the tin was precipitated in pulverulent form. The Goldschmidts subsequently secured control, and for the last three years no stripping has been done here, but the briquettes have been sent direct to Essen, where the tin was recovered by the dry chlorine process, and the remaining iron sold to the steel makers. On the stoppage of shipments to Germany, it was decided to modify the heating furnace in such a way that the tin would be melted after the removal of the solder, and the metal thus obtained in a form suitable for sale to English tin-smelting firms. The amount of tin remaining on the briquettes is not very large, and British steel makers do not object to its presence in the briquettes. So the business of the firm continued, though naturally only in makeshift manner. It is well known that the recovery of tin from clean scrap produced during the construction of cans and other ware from tin-plates has been conducted for many years in England, on the Continent, and in America. But the recovery of tin from discarded cans presents a different problem. The removal of fat, grease, syrup, varnish, and paper involves the use of a plant of large capacity, consumption of considerable chemical solution, and a great deal of heat. The cost of collecting and transporting bulky material constitutes in itself an economic problem of importance. In a populous centre such as London, it is possible to make contracts with big hotels, and wholesale manufacturers of articles of food, but for the collection of waste tins rejected by the householder recourse must be had to the municipal dust-collector. In spite of these disadvantageous conditions, the Goldschmidts' detinning works in Germany, France, and Limehouse have been profitable. Before the war, arrangements had been made, I believe, to establish two similar enterprises in the United States, but these schemes will probably be abandoned. As far as I am aware, no one has ever used chlorine as the agent for removing the tin except the Goldschmidts. The caustic-soda process has been employed by many inventors who have obtained patents for variants of the electrolytic bath. One notable enterprise founded on this principle is the Vulcan Detinning Co., in America, which by winning a patent suit two years ago, forced the American Can Co. to close its detinning works. I ought to add that, according to the Goldschmidt process, the tin is recovered as tetrachloride, a chemical in request among silk manufacturers for giving a body or weight to the silk. In this form the tin brings a far higher price than if sold as impure metal or as oxide. The tin produced by the caustic-soda process has a property similar to that of zinc dust, of oxidizing directly it is heated, and it has to be remelted. Unfortunately, the silk industry of England is of too small proportion to be of use as an outlet for tetrachloride. No doubt a more profitable method of treating the scrap will be evolved, that will recover more tin and in a more valuable form.

JOPLIN, MISSOURI

PICHER LEAD CO.'S EXTENSIVE PROSPECTING IN THE MIAMI FIELD. —NEW ZINC AND LEAD AREAS.—NEW MILL AT ALBA.

The most extensive prospecting campaign started by any company in the Missouri-Kansas-Oklahoma district in recent years is that under way by the Picher Lead Co., which is operating several churn-drills in the north Miami, Oklahoma, district. While this work has been going on for almost a year, the Company has been reticent about giving any information regarding the nature of its ore discoveries. Recently it has been announced that extensive deposits of ore have been cut at considerable depth in many holes, and it is likely the Company will begin active mining development soon. The region in which the prospecting has been conducted is developing into the greatest lead-producing area in the entire Missouri-Kansas-Oklahoma district, other companies on nearby tracts having opened deposits of high-grade galena. The Picher Lead Co. is a heavy consumer of galena concentrate, and will doubtless utilize the greater portion, if not all, of its production of lead ore, while the zinc-blende which is associated with the galena can be sold to the various smelting concerns purchasing concentrate in this district. Recently the Picher Lead Co. has added a third sublimed white-lead unit to its plant at Joplin, and made other extensive improvements, costing, in the aggregate, more than $100,000.

A discovery of lead ore in an isolated region, northwest of Miami, is reported by Samuel Moss, owning land two miles west of the Neosho river, and 2½ miles west of the nearest producing mine, the McConnell & Barnes No. 2, which, in itself, is quite distantly removed from the other mines of the Miami field. The drill-hole on the Moss land is reported to have penetrated galena at a depth of 70 ft. and continued in ore down to 120 ft. This is the first discovery of importance made west of the river, although some 'shines' were found in previous drilling on land several miles south of the new area.——Thomas F. Coyne, considered one of the luckiest operators of the entire district, has opened a shallow bonanza of lead and zinc on a lease of the Missouri Zinc Fields land, southeast of Webb City. He cut the ore in the only strip of land in that vicinity that had not already been extensively mined. All around his new mine are old producers, the drifts of which had failed to penetrate the rich orebody just opened by Mr. Coyne. The ore occurs at a depth of 30 ft., and continues down to 75 ft. The ore yields 10% lead and zinc when treated by a nearby custom mill.——Mining activities will probably be resumed soon at the property of the Amalgamated Lead & Zinc Co., operating on the Granby Mining & Smelting Co.'s land in the northwest part of Joplin. For some time this mine, one of the former big producers of the Joplin district, has been idle while drill prospecting has been conducted some distance from the old workings and in virgin ground. An unusually good blanket formation of zinc and lead ore is reported in several holes at a depth of 114 to 120 ft.——The Granby Mining & Smelting Co., in drilling on practically virgin land in the Leadville Hollow region northwest of Joplin, has cut lead and zinc ore at a depth of 120 to 138 ft., and will sink a shaft on this prospect in the near future. It is only recently that the Granby company has essayed to mine, its previous function having been that of a leasing company only. Some

time ago this Company opened the B. & H. mine in northwest Joplin, constructed a large concentrating plant, and is now producing steadily from this property. The scene of the new find is in a region mined only to a very shallow depth in the past.

A new concentrating plant of 200-ton daily capacity has just been started by C. H. Britt, Charles H. La Pierre, W. T. Landrum, and J. McWilliams, on the Sunflower land at Alba. The plant was remodeled from the old Brown mill, and all equipment is new. Two trams, each 300 ft. long, connect the company's shafts with the mill, which is equipped with a large hopper capable of holding 500 cans.

DEADWOOD, SOUTH DAKOTA

WORK AT THE MONARCH, ORO HONDO, HEIDELBERG, BUNKER HILL, AND OTHER MINES.

Hanson & Sweet, who are leasing on the Monarch property, near the head of Two Bit gulch, have made their initial shipment of ore to the Omaha smelter. Its value was about $50 per ton in gold. These men were fortunate enough to secure a lease on a portion of the Monarch property which had been idle for upward of 30 years. In the old wagon road leading to the adit from which they are taking ore, were 'jack pine' trees, in the trunks of which were counted 30 rings, each of which indicated a year's growth. The shoot is holding ont well, and the lessees hope to maintain regular shipments during the life of their lease, which is for two years. In the same neighborhood, R. I. Zipp has opened a shoot of similar character, which, however, is not quite rich enough to ship. It assays $15 per ton, of which $9 is free gold. None of the custom mills in the Black Hills is equipped to save this gold, so Mr. Zipp has his ore on hand and is meanwhile endeavoring to develop enough to warrant the construction of a mill.

Now that the superintendent, Mr. Talbert, at the Oro Hondo, has things in good order, continuous progress in sinking is anticipated. During September, which was the first full month under his superintendency, the shaft was deepened 75 ft. The best week's run was 19 ft., made the last week in the month. Mr. Talbert hopes to make 100 ft. per month, or better, when he gets things thoroughly organized. Hoisting from the bottom to the 1000-ft. level is done with an auxiliary engine placed on the latter level. The shaft is now 1200 ft. deep.

At the Heidelberg, the shaft following the ore from the main adit-level has reached a depth of 35 ft., giving assays from as wide an orebody as on the main level. Sinking is being done with a windlass.

The New Reliance company was unfortunate enough to lose the hoist-house at the Bunker Hill mine as the result of a forest fire, and thus an important source of ore supply was cut off. Other parts of the property are being drawn upon to keep the mill busy while the damage is being repaired.

An assessment of 2c. per share has been levied by the Custer Peak Milling & Ore Co., with the proceeds of which work will be resumed in the shaft. The shaft is now 250 ft. deep, with several hundred feet of laterals, the whole exposing a good quantity and grade of copper ore. At the Jungle property, adjoining, work on construction of a copper leaching plant has been suspended on account of the low price of copper.

Rehsamen & Burns, who are developing their Harrison property, at the head of Blacktail gulch, are developing an orebody which promises to be profitable. Assays show a gold content of $6, $8, and $10, in a body of fair size. The shoot lies nearly horizontal, and is reached through an adit, so that it can be cheaply mined.

Robert Mulford, who recently visited the Black Hills to investigate mining possibilities, and particularly the Golden West and other properties near Rochford, was highly pleased with the results he secured, and is expected to stand sponsor for large operations which will likely commence in the near future. Mr. Mulford, like a number of other large operators who have visited the Hills in the past year or so, was looking for a promising orebody assaying $2 or $3 gold per ton. Since the exploitation of the big deposits at Juneau, Alaska, engineers have been searching for similar opportunities, and it is thought that they will find them in the Black Hills. The Homestake is one of the world's largest known bodies of gold ore, and it is not reasonable to presume that it is the only deposit of its kind in the Black Hills.

The Mogul company has leased the Clinton property, on lower Nevada gulch, from the owner, Charles Thompson, of Whitewood. The property is stated to contain an immense deposit of quartzite, which can readily be cyanided. An air-compressor, drills, and other equipment are being installed, and mining will be done by sub-lessees. It will be a round-about journey for the ore from this property to the mill, as it will be necessary to load it in narrow-gage cars, haul it to Englewood, transfer to standard-gage cars, and transport to the mill. The railroad has made a rate of 65c. per ton on the handling of the product.

HOUGHTON, MICHIGAN

TAMARACK REGRINDING MILL.—SUSPENSION OF WORK AT PROMISING PROPERTIES.—MINE ACCIDENTS.

In the midst of general curtailment and reduced wages, it is interesting to note that the work on the new regrinding mill for the Tamarack sand on Torch lake is still progressing. A contract to construct a spur from the Mineral Range line to the plant has been awarded to a Houghton firm. This work will be rushed, and the immediate installment of equipment will be possible.

Every now and then the suspension of mining operations at some property is announced. There are several in the copper country which have been in the exploration and development stage for so many years that they are considered mines by the people of the district. On September 1, work was stopped at the Wyandot. Reorganization of the company will be necessary before further work can be undertaken. In most cases these forced suspensions have come at times when the properties had reached the most hopeful stage of development. For that reason these shut-downs seem most unfortunate.

The report of the Houghton County mine inspector shows a total of 29 casualties for the year ended September 30, 1914. This county includes, besides numerous claims being developed, the mines of the Calumet & Hecla, Copper Range Consolidated, Quincy, Winona, Superior, Isle Royale, Hancock, Franklin, Kearsarge, and Centennial. The largest number of casualties was four at the Baltic. The reports of the inspector since 1888 to date show that the highest percentage of accidents was in 1895, when, with 7249 men employed, there were 44 fatalities. During this year, however, 30 men were suffocated at the Osceola. The percentage for 1914 is 0.0022 with 12,954 men employed. The only year which shows a better percentage is 1899, when with 13,057 men employed, 27 accidents occurred, giving a percentage of 0.0021. The report of the mine inspector of Keweenaw county shows four mine fatalities during the past year.

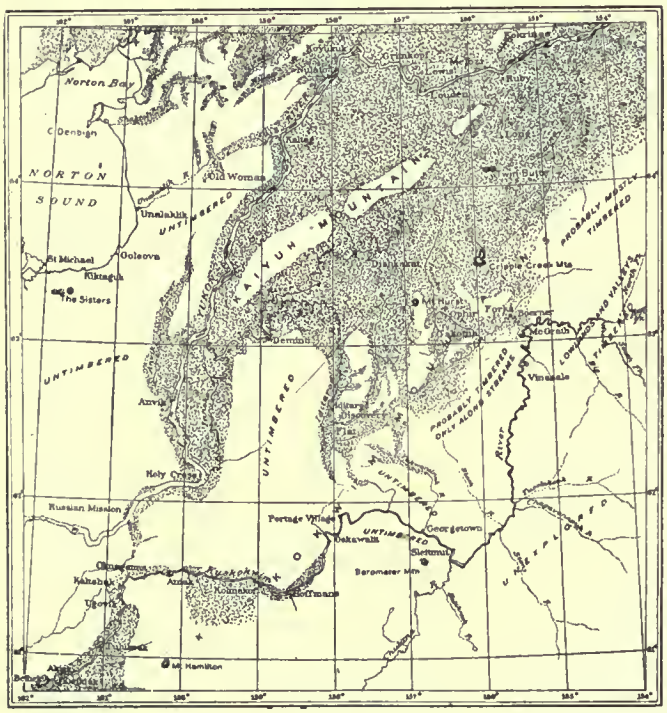
The entire North Webb City sheet-ground district is threatened with a shut-down on account of a misunderstanding regarding pumping expenses at the Providence mine. Heretofore this expense has been divided among the various operators of this area who have been benefited by the pumps of the Providence company. If these pumps are stopped, other companies must start individual pumps or be flooded. The latter seems to be the probable result, in view of the low prices for zinc ore that are now prevailing.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

The Iditarod-Ruby region is described by Henry M. Eakin in *Bulletin* 578 of the U. S. Geological Survey, and is replete with three large maps. Under exceptionally difficult conditions, Mr. Eakin made this investigation late in the summer of 1913. The topography of the region is diversified by broad lowlands of less than 500 ft., rolling uplands of 1000 to 2000 ft., and local mountain groups of up to 4500 ft. elevation. The area is drained by the Yukon and Kuskokwim river systems. There is not much rainfall, never above 20 in. per year. Winter lasts from October to April. Mining may be done during about 120 days. Violent storms are comparatively rare. The timber-line, the maximum elevation at which trees grow in the Iditarod-Ruby region, is about 2000 ft. above sea-level. The general distribution is shown on the cut accompanying



MAP OF IDITAROD-RUBY DISTRICT. SHADED PORTIONS SHOW TIMBERED AREAS. BETHEL, FROM WHICH CORRESPONDENCE IS PRINTED ON THIS PAGE, IS IN THE EXTREME LEFT BOTTOM CORNER.

these notes. There are plenty of fish in the rivers, and only small game is plentiful. There are about 1600 people in the Iditarod, 150 in the Innoko, and 1000 in the Ruby district. Steamboat service is maintained on the rivers in the season. Mail service continues all the year round to most of the centres, and there is wireless and telephone service available in many places. Labor is plentiful, and receives from $5 to $6 per day, with board. Fuel used is wood, costing from $6 to $15 per cord. Rough and dressed lumber at Ruby costs $50 and $80 per 1000 ft., respectively. After describing the geology of the area, Mr. Eakin discusses the veins and mineralization. Quartz veins are common in the Cretaceous sedimentary rocks of the Iditarod district, are generally gold bearing, but have not yet proved to be worth mining. Quartz veins cut the rocks in the Innoko district, and are common in acidic dikes that intrude the sedimentary rocks. They occur mostly as close stockworks. The Independence mine, on Carter creek, has a vein 2 ft. wide, which has been opened to 90 ft. In the Ruby area, quartz veins are a common feature of the metamorphic rocks. The veins in these districts probably supplied the gold for the placer accumulations. Practically all of the work done in the Iditarod-Ruby region has been in placer mining, which is fully described in the work. The Yukon Gold Co. has a large dredge working in the Iditarod district, on Flat creek. The 1913 gold output of the Iditarod, Innoko, and Ruby districts was about $1,860,000, $280,000, and $850,000, respectively.

A gold nugget worth $1900 was found on Long creek by Xavier Ditz and associates about the middle of September. Two others, worth $300 and $400, were also unearthed recently.

BETHEL

(Special Correspondence.)—From the recent development work on Bear creek, a tributary to Tuluksak river, and on other points on Kuskokwim, the fact seems established that this will be one of the large gold-producing rivers.

R. S. Eskridge, a prominent and enterprising mining man from Louisiana, brought in a No. 5 Keystone drill this spring for prospecting a group of claims which he bought last summer, and some which he holds under option, with the intention of putting in a dredge. It is reported that he has proved a pay-streak 300 ft. wide and is not through it yet. Part of this averages $5 per cu. yd., and $2,000,000 is in sight. Mr. Eskridge has sent out orders for a dredge to be shipped in next spring.

Brice & Hamachmen have started to work on their group of claims. They have ground that yields $1 per sq. ft., and promises even more. They are putting on all the men they can get at $10 per day with board. There are a number of others who work their claims, and some of these have ground that yields, when shoveled into boxes, $100 per man.

A report came from Candle creek that 35 men are at work and have taken out 2200 oz. This creek is a tributary to Kuskokwim river, and empties into the Kuskokwim a few miles below Takutna from the right limit.

The U. S. Geological Survey steamer *Yukon*, with Richard R. Lukens in command, called in at Bethel. Mr. Lukens said that Kuskokwim bay and river is one of the best to navigate on the Alaskan coast, and ships drawing 15 ft. of water can easily come up to Bethel, and that the main or Eek channel, through the flats, is well defined, which can be easily seen on the excellent chart made by the Survey. Mr. Lukens is a man of ability, and his quick and active work is greatly appreciated by the reputable citizens of this country. This work, in connection with A. G. Maddren's work on the Geological Survey, will undoubtedly open one of the most promising mining areas of Alaska, which can be seen from the above report of the recently developed mines on the Kuskokwim.

Bethel, August 27.

FAIRBANKS

Owing to cold weather in the second week of September, operators on Cleary creek were forced to shut down. An agricultural fair was held in Fairbanks during the month, and excellent vegetables of all kinds were displayed. There were also samples of quartz, some of which were high grade.

JUNEAU

A 12-page illustrated pamphlet has recently been issued by the Alaska Gold Mines Co., from which the following extracts are taken:

Altogether 22,137 ft. of development work was done during 1913, and about 20,000 ft. during the first eight months of 1914, or a total of over 42,000 ft. since the beginning of most active mine development, about the first of 1913. This total does not include several thousand feet of diamond-drill work, which has been done to prove the thickness and value of orebodies, which method of development, where applicable, is much cheaper than cross-cutting in the regular way.

The mill of 6000-ton daily capacity is nearing completion, and the first unit, having a daily capacity of 1500 tons, will be in regular operation by or before the end of December this year. According to present schedule, it is thought that the remaining three units of the plant will be completed at intervals of a few weeks, so that the total plant is expected to be operating at its full rated capacity of 6000 tons per day by or about the middle of 1915. It is necessary to say that as a result of improvements and simplification of the metallurgical processes to be applied to the treatment of these ores, which have been devised since the original designs of the milling plant now under construction were completed, it is estimated that this plant will have an economical capacity of about 8000 tons per day, instead of 6000 tons as originally contemplated, and that by the installation of a comparatively small amount of additional machinery, it may be brought up to a capacity of 10,000 tons per day without extension of buildings.

The construction of a water-power plant, and system of distribution to provide a minimum of 6000 hp., and a maximum of 8000 hp., is practically completed. The principal feature of this development was the construction of a concrete dam 700 ft. long on its crest and 165 ft. high, to create a reservoir. This dam has been finished, and on September 1 the water had already risen 62 feet.

Those in control of and interested in this Company may, therefore, look forward to operations within a few years' time at the rate of 7,000,000 tons per annum, at a profit, on normal grade ores, of at least 75c. per ton, yielding an annual profit of approximately $5,000,000.

NELCHINA

According to L. F. Shaw, commissioner at the Nelchina camp, there are only 30 men there at present, most of the men who rushed there last winter and spring having gone to other districts. Several promising prospects have been found. A shaft on Crooked creek is down 190 ft., without reaching bedrock.

NOME

The last steamer for Nome for the season, the *Victoria*, left Seattle on October 18. On the Kougarok river, the Bering Dredge Co. has been hydraulicking, which was expensive work, so a 2½-cu. ft. Union Construction Co. dredge will be erected next spring. J. F. Mathews is general agent. Five inches of snow fell at Candle on September 29. *The Nome Weekly Nugget* is publishing a mining and dredging booklet dealing with the district.

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—The George H. Crosby Mining Co., of Bisbee, has applied at Phoenix for 40 claims in the California district. This was done to enable publication notices and assessment work being done by 1915.

Bisbee, October 12.

The vein in the Commonwealth mine at Pearce was cut on No. 8 level last week, picked samples assaying $11 per ton. As further driving was expected before cutting the two shoots, the development is encouraging.

GILA COUNTY

Good progress is being made with the 300-ft. stack at the International smelter at Miami. The contractors, Taft & Short Bros., of Chicago, in one day recently, drove 1200 rivets besides putting up 22½ ft. of regular course work, with two gangs of eight men each.

GRAHAM COUNTY

(Special Correspondence.)—In the Clark district, T. D. Morris has three shifts of miners working in the Gold Cord mine. Ore from the 200-ft. level is to be sent to the mill early in November. These claims contain gold, silver, and copper, and are said to be a valuable group.

Pima, October 12.

GREENLEE COUNTY

Directors of the Arizona Copper Co. from Scotland have been visiting the mines and smelter. Some sales of copper are being made by the Company, and the directors stated that there is no intention, at present, of shutting down.

PINAL COUNTY

(Special Correspondence.)—Driving is being continued on the 500-ft. level of the Kelvin-Suitana mine, at Superior, with good results. Lessees recently sent a car of carbonate ore, assaying 15% copper, to the Hayden smelter. The new mill is nearly finished, the last load across the Gila river being a 6-ft. Hardinge mill. Rain has done a good deal of damage to dumps and old workings.

Superior, October 12.

YAVAPAI COUNTY

The second annual Northern Arizona Fair was held at Prescott last week. Besides the machinery display of the Arizona Mine Supply Co., and powder by the Hercules Powder Co., Mohave and Yavapai County minerals were well represented. The former is mostly a gold producer, with some lead and zinc. The latter county is mainly a copper producer, and the United Verde and Humboldt smelters sent fine exhibits of ores and products. The Crown King, War Eagle-Gladiator, Wildflower, Tiger, Lincoln, Savoy, and others showed samples of copper and silver-gold ores from the Bradshaw mountains. Many other districts displayed their ores.

The United Verde Extension company has published a circular in which it states that about 6000 ft. of underground work has been done since James S. Douglas assumed the management two years ago. Only recently was anything valuable opened. The Edith shaft is down to the 1200-ft. level. Cash and bills receivable amount to $8571.

CALIFORNIA

AMADOR COUNTY

The orebody recently cut at 2600 ft. in the Keystone mine is developing satisfactorily.——Two rope drums from the Zeila mine at Jackson have been purchased for the Keystone hoist.

GLENN COUNTY

It is said that New York people are expected soon to inspect the old chrome mine near Newville, which is being opened by Willows men.

PLUMAS COUNTY

At the Rose Quartz mine, Onion valley, near Quincy, the adit is in 225 ft., and in a 30-ft. shaft at the end of the adit 31½ ft. of rich ore has been cut.

SHASTA COUNTY

The electric smelter at Heroult has been short of manganese ore, as the supply from the mine in Glenn county was exhausted. A mine in Mendocino county is being developed. The reported discovery of manganese ore across the river from the smelter was not up to expectations.——Prospecting is being done below No. 5 adit of the American mine at French Gulch. This mine adjoins the Gladstone.——The Milkmaid company is prospecting the Franklin with a diamond-drill.

H. F. Musser is manager.——The Shasta County Farmers' Protective Association has obtained an order from the United States district court for the Mammoth Copper Mining Co. to show cause on October 26 why the permission to operate its smelter at Kennett should not be revoked, and pay certain costs to the Association. The general manager, G. W. Metcalfe, stated that he was not surprised at the action. The output of copper in September was 800,000 lb.——The Coram station of the Southern Pacific has been closed.

On account of the abundance of water for development of electric power, and the large deposits of limestone in this county, Boston capitalists, represented by Charles G. Carter, have secured an area of land near Heroult containing limestone. It is proposed to manufacture calcium nitrate, the first unit of a plant to have a capacity of 100,000 tons per annum, costing about $300,000.

SIERRA COUNTY

The Bald Mountain mine is to be developed by W. Copeland, who has it under bond and lease. Buildings and plant are to be erected.——The Oxford quartz mine is being sampled by Salt Lake City people.——A Keystone drill has been working during the summer at the Lost River gravel claims. Ten holes sunk to bedrock average 155 ft. each. Gold-bearing gravel was found in four holes. An adit will be driven to open the channel.

TEHAMA COUNTY

The Ash Creek Mining Co., composed of Red Bluff people, is erecting a 5-stamp mill and other plant.

COLORADO

LAKE COUNTY (LEADVILLE)

The mining situation in this district is quite encouraging. ——The zinc smelter is again in full blast.——The Penn properties on Breece hill are to be reopened by Joseph Lanphier. ——The Big Four shaft is to be sunk 350 ft. from its present

THE SMELTERS AND MOUNT MASSIVE, LEADVILLE.

depth of 768 ft., and the Company is steadily shipping rich gold ore.——During September, the D. & R. G. railroad moved 895 cars of ore from the district, not including that to the Arkansas Valley plant.

OURAY COUNTY

A new furnace is being erected at the Wanakak smelter, while the plant is receiving a good deal of ore for treatment. Ten more stamps have been added to the existing ten. A high-tension power-line has been constructed to the mine.—— Lessees at the Pink Rose mine, near the Camp Bird, have 8 ft. of $20 ore opened.

PARK COUNTY

The Tomboy company of Telluride, San Miguel county, has started extensive work in the south Mosquito district. Sixty men are employed, and prospects are favorable.

SAN JUAN COUNTY

Shipments of crude ore and concentrate from Silverton in September were 308 and 2310 tons, respectively.

TELLER COUNTY (CRIPPLE CREEK)

During August, Stratton's Independence reports that the production was 3630 tons of ore averaging $5.32 per ton; low-grade mine and dump ore milled totaled 11,870 tons; working profit from milling department, $8940; loss on mine department, $3530; and net profit to Company, $5410.——Lessees at the Isabella Mines property have opened 7 ft. of 4-oz. ore, 12 in. of which is worth $2300 per ton.——Lessees in the Hiawatha mine, on Beacon hill, have opened about $20 ore at the 100-ft. level.——Lessees on the El Paso estate have found $74 ore in an 80-ft. winze.——Last week the El Oro mine shipped 1200 tons of $12 ore. The vein is 32 ft. wide and 110 ft. long.——The Cripple Creek Cyanide & Mining Co. has been formed, with Howard Schultz as secretary, and a custom mill is to be erected.——A vein 20 ft. wide, assaying $18 to $20 per ton, has been cut at 300 ft. in the Abe Lincoln by C. Porter, a sub-lessee. Development at 400, 500, and 800 ft. is extremely encouraging.——Water from the Roosevelt drainage tunnel amounts to 10,000 gal. per minute.——The Blue Flag shaft is now down 1100 ft.——The Miller lease at the El Paso is producing $31 to $33 ore from a 4-ft. vein.—— The Mary McKinney dividend has been passed.——On October 20 the Portland company paid its quarterly dividend.

IDAHO

BLAINE COUNTY

The new mill at the Nau Aug mine, 12 miles from Hailey, will be ready for work on November 1. It consists of a crusher, rolls, and concentrating tables for silver-lead ore. K. C. Wooley is in charge.

SHOSHONE COUNTY

The Caledonia Mining Co. has distributed 1c. per share, or $26,050, to its shareholders. This will be done each month. It is the first since the recent settlement of litigation with the Bunker Hill & Sullivan company.——The Interstate-Callahan produced 3493 tons of high-grade zinc concentrate in September. The winze from No. 4 adit is down 225 ft., in ore all the way.——Net earnings of the Stewart company were $75,000 in September, against $82,000 in August.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.)—Why only two mines in the Michigan copper district, the Mohawk and the Wolverine, are operating full time, is explained by the fact that practically all of the normal production of these mines is sold to American consumers. The mines which produce copper for foreign markets must either reduce the scale of operations or, better, find domestic consumers. There may be relief for them in the large and growing automobile industry at Detroit. Large shipments have been made by the lake routes, and it is interesting to note that rail shipments are being called for.——At the Quincy, 'rock' is being hoisted from three shafts at full capacity.——With the men working half time, the output of the Baltic, Champion, and Tri-mountain mines is 60% of normal.

Houghton, October 15.

MONTANA

The Montana Power Co., including all subsidiary companies, reports for the quarter ended September 30, and the nine months ending that date, as follows:

	Quarter.	9 months.
Gross earnings	$908,864	$2,812,766
Operating expenses and taxes	281,525	839,667
Net earnings	627,339	1,973,099
Interest accrued	226,607	719,216
Surplus	400,732	1,253,883

FERGUS COUNTY

The Barnes-King Development Co. has issued a statement concerning its Piegan-Gloster mine, near Marysville. It says

that the original Gloster mill, worked in 1880 to 1888, had 60 stamps, plates, pans, and settlers, recovery being by amalgamation only. Nearly all of this equipment was sold in the latter year. The present Company found the building in good condition, and new machinery now being installed includes a gyratory crusher, three Chilean mills, concentrating tables, classifiers, and cyanide plant. A 2500-ft. surface tram formerly brought ore to the mill from the mine, but now a 1700-ft. aerial tram will convey it from the Norman adit, which is being driven to develop the Ophir and Piegan claims. The new mill, of 100-ton capacity, should be ready early in 1915. If the Montana Power Co. cannot supply current by then, the boilers and engines left by the old company will be used for the time. The old Gloster five-compartment shaft is being overhauled.

SILVERBOW COUNTY

Owing to an accident to the Black Rock shaft of the Butte & Superior, the mine and mill are temporarily closed. This shaft has been in bad order for some time, and 300 ft. will be retimbered. Only 150 out of the 1150 men employed will be needed for mine and mill repairs. J. L. Bruce is manager of this great zinc-producing property.——The Tuolumne mine has been shut down on account of the copper market.

NEVADA

ESMERALDA COUNTY

From a rise above the 1017-ft. level of the Jumbo Extension, 58.3 tons of ore has been settled for at 13.04 oz. gold and 31.1 oz. silver per ton, and 13.1% copper, or $302.55 per ton.

HUMBOLDT COUNTY

The National Mines Co. is overhauling its mill, and will probably operate it through the winter.

LANDER COUNTY

A number of mills and treatment plants worked in the Austin district in the past, and several tailing dumps remained from these operations. Hart and Cameron are now treating one lot of 30,000 tons by cyanide, and when finished will move their plant to a 100,000-ton heap below the Austin-Manhattan mill.

LINCOLN COUNTY

Owing to the discovery of a small vein of rich gold ore, a rush has set in for an area 22 miles east of Las Vegas and one mile west of the Colorado river.

LYON COUNTY

The Pittsburgh-Dolores Mining Co. is working the Rockland mine, south of Pine Grove, in charge of E. J. Schrader. The property is an old producer, and about 15,000 ft. of work was done. About three years' ore is in sight. An 80-ton plant with rolls and cyanide plant is being erected.——The Mason Valley company has stopped work at its mines on account of the copper market. About 250 men are deprived of employment through this action. The smelter is to close down shortly.

NYE COUNTY

(Special Correspondence.)—Up to 60 days ago, mining in the Tonopah district was confined to an area of about 2 by 4 miles, with Mt. Oddie in the centre. Prospecting had been done outside of this limit, but without anything startling. Two months ago John Shipway and Tom Taity discovered what they called a contact between rhyolite and porphyry about four miles north of Mt. Oddie, resulting in the discovery of ore which panned free gold. This was interesting, as Tonopah is essentially a silver producer. Three pioneer lessees of the district, R. Dougherty, P. Mooney, and H. McNamara, leased the new find and have been sacking ore from the surface down, using a windlass in sinking. From 15 to 20 leases have since been taken up, with good surface indications. H. Campbell and R. Kelly have milled four tons of ore yielding 2 oz. per ton. About six others are sacking ore. The Tonopah Mining company's engineers examined the claims and are waiting for further development. The strike of the ore-shoots is toward the contact, and so far the wall rock on both sides is the same. A townsite has been laid out and named 'Tonogold,' but it is really a suburb of Tonopah. Generally, considerable optimism is felt regarding the new gold area.

Tonopah, October 17.

Ore production from seven mines at Tonopah last week totaled 11,533 tons valued at $233,554.——Some September returns were as follows: Belmont, 14,845 tons, yielding 306,783 oz. bullion for a profit of $121,165; Tonopah Mining, 12,011 tons for 211,690 oz. and 64 tons of concentrate, and a profit of $65,350; and Jim Butler, 3417 tons for $20,842 profit.——Ore from the North Star is to be treated at the West End mill.

STOREY COUNTY

The *Virginia City Chronicle* summarizes mining operations on Comstock lode during the past week as follows: Consolidated Virginia rising on 6-ft. vein above the 2500-ft. level, 71 cars of low-grade ore being saved. Ophir makes good progress in reopening old workings of the Central tunnel to develop low-grade ore. The Mexican continues work on the 2500-ft. level winze at 2650 ft. also, sinking and timbering station. Union Consolidated west cross-cut at 2650 ft. in the Union winze is in diorite at the 236-ft. point. The C. & C. pumping plant is working smoothly and holding water at all points. The Yellow Jacket mill shipped a bar of bullion, and 648 tons of ore was placed in bins. The Crown Point suspended stoping for the present on the 1300-ft. level. The Belcher extracted 354 cars of ore from the 1600-ft. level stope. Water held 95 ft. below the 1600-ft. station of joint incline. The Overman continues reopening old workings on the 1300-ft. level. The Caledonia extended the northwest drift from the rise above the 1100-ft. level, through quartz, giving fair assays. The South drift on the 200-ft. level of the joint Confidence-Challenge-Imperial shaft is all in quartz of low assay value.

Fire broke out in an old stope on the 2500-ft. level of the Mexican mine on October 19. Bulkheads were placed on the 1600 and 2000-ft. levels to hold back the smoke. According to T. F. McCormick, of the United Comstock Pumping Association, and of the Ophir and Con. Virginia mines, there is no danger to the pumps on these properties.

WHITE PINE COUNTY

Mining claims and a mill at Seligman, near Hamilton, which have been idle for many years, have been jumped, and the ownership is to be decided in court. It is alleged that the required assessment work has not been done on the claims. The mill cost $100,000 about 25 years ago.

NEW MEXICO

SAN MIGUEL COUNTY

(Special Correspondence.)—For the treatment of molybdenite ores in the El Porvenir district, Margarito Romero has devised a successful process after a most discouraging series of tests, in which not more than 47% of the mineral was recovered. A concentrating plant has been erected, and the new process extracts from 80 to 95%. The ore is crushed in a flat mortar, after which it is roasted and run through a series of screens. The tailing is treated in a flume of running water. The interfering mineral in the ore is copper, but the final product is worth $1.50 per pound in New York.

Silver City, October 15.

NORTH CAROLINA

YADKIN COUNTY

(Special Correspondence.)—The Gross and Dixon Gold Mining Co., an Omaha, Nebraska, concern, is making extensive improvements to its mine and mill. At the former, retimbering is being done, and hoisting and compressor machinery is being installed; and in the mill, modern cyaniding apparatus is to be put in. The mine has been developed during several

years, and a large tonnage of profitable low-grade and a fair quantity of very rich ore is in sight. Gold is in an iron-copper sulphide. George E. Price is in charge of the property.

Cana, October 2.

SOUTH DAKOTA

Lawrence County

According to the monthly statement of the Homestake Mining Co.'s employees' aid fund, published in the *Lead Daily Call*, 141 persons received a total of $2703 in September. Among the list is $800 for the late manager, T. J. Grier. This fund is for death, injury, sickness, suicide, and insanity. Receipts from employees totaled $2396, and the Company $1000, and including cash on hand, etc., the total available in September was $41,024. Cash at the end of the month was $38,321.

UTAH

Beaver County

Forty to fifty per cent zinc ore, with some silver, has been cut in the Leonora mine in the Star district. A good deal of development is proposed.——On October 30 and 31, all of the material and auxiliary plant of the Montreal mine of the Glasgow & Western Exploration Co. will be sold at auction. The Company has spent about $5,000,000 during the past 12 years. This mine is five miles from Milford, and is in charge of Frank Schuyler.

Juab County

The Eagle & Blue Bell shaft is being sunk four feet per day, and is now about 1700 ft. deep. A 16-ft. sump will be sunk for pumps.

Ore shipments from 20 mines in the Tintic district last week totaled 128 cars.——A mill will probably be built at the Grand Central mine at Tintic, to treat low-grade copper ore found down to 2200 ft., according to the manager, C. E. Loose.

Summit County

The new Park City Mills' 50-ton plant is in full operation, and gold-silver-copper ore from the American Flag mine is being treated. The chlorination process is being used, operating a Knight-Christensen roasting furnace. George H. Scibird is in charge.——The Michigan-Utah Mining Co., operating about four miles west of Park City, is to be reorganized. A new 1500-ft. adit has been started to cut the orebodies at 600 ft. vertical depth.

Uinta County

According to A. S. Brown, a property owner in Lucerne valley, 115 miles east of Salt Lake City, there are good chances for prospectors in the Uinta mountains.

WASHINGTON

Pend Oreille County

The Bead Lake Gold-Copper Mining Co., which has been developing a group of 20 claims near Newport for the past 10 years, has opened a vein about 12 ft. wide in the lower adit, at a depth of 300 ft. The ore assays high in lead and silver, also $2 to $6 per ton in gold. Ore is to be shipped, and for the low-grade material a mill may be erected. W. E. Allen is secretary and the largest shareholder, resident in Spokane.

Stevens County

The United Copper Co., at Chewelah, has engaged 70 men in Spokane, making a total of 115 employed. The Company has a contract to send 125 tons of ore and some concentrate daily to the Trail smelter.——The Gwin mine at Kettle Falls is being reopened after a shut-down due to low water. A 50-ton concentrating plant is ready for work.

CANADA

Alberta

Spokane people have organized another company to exploit the oil districts of the Sweet Grass-Milk river and Flathead area. A total of 2920 acres has been secured. It is estimated that the oil strata of the Calgary field are at a depth of 3500 ft., and the Sweet Grass at 2000 ft. Drilling is under way at the latter place, and the new concern is erecting a rig for sinking a well.

Ontario

The annual report of the Hudson Bay Mines Co. shows that the output of silver was 393,360 oz., worth $196,436, from the Cobalt property. This has been worked out, and is closed. A balance of $52,561 remains after paying all expenses. Since 1907 the mine has produced 5,604,168 oz., valued at $2,965,523, from which large dividends were paid. The Company controls the Dome Lake mine at Porcupine, and spent $119,375 on it during the year. Development at this property is promising. A. H. Brown is general manager.

On October 15 the Seneca-Superior company paid a dividend of 10%, equal to $47,638, and making a total of $595,580.—— The Coniagas company has its No. 4 shaft, in the town of Cobalt, down 150 ft.——The report of the Dome Mines Co., Ltd., shows the value of gold recovered in September to be $99,301, comparing with $90,893 in August and $82,983 in July. Gold recovered for the twelve months ended September 30 totaled $1,204,263. The value recovered per ton milled in September was $4.52.——Gold production from the Tough-Oakes mine to date is $100,000. The mill has a capacity of 40 tons per day, but the new one will treat 100 tons. There are 125 men employed.——The Dome mill treated 21,940 tons in September, yielding $99,302.

KOREA

The Oriental Consolidated Mining Co.'s clean-up for September was $132,200. In August the mills treated 27,081 tons of ore yielding $119,210. The rainfall was 28 in., and 22½ in. in July, consequently the Tabowie, Taracol, Charabowie, and Candlestick mines were partly flooded. The season was not over on September 5. The war has not had any serious effect on operations, save a hold-up of dynamite and rails in neutral ports. Supplies have been ordered from America. Cyanide has risen from 15 to 50c. per pound. Labor is satisfactory. Foodstuffs have advanced, and costs will rise.

MEXICO

According to a recent *Daily Consular Report*, a decree issued under date of September 15, 1914, by Governor Eulalio Gutierrez, fixes the minimum wage in the state of San Luis Potosi at 75 *centavos* per day, to be paid in cash, which at the ruling rate of exchange is equivalent to about 21c. U. S. currency. In mines the minimum wage is fixed at ₱1.25, or about 35c. U. S. currency. The 9-hour day is also decreed. Employers who have been paying more than the minimum are forbidden to reduce wages to the minimum. Workers on farms must be supplied free water, wood, and shelter. By the same decree, company stores are abolished. All debts contracted by laborers to employers expire by limitation in one year. Employers are prohibited from placing any obstacle in the way of laborers who desire to change their place of employment or to accept other employment. The wages of laborers are exempted from garnishment. The decree provides that a landowner who furnishes to the tenant the land, implements, animals, and seed shall not collect more than 25% of the crop for rent and reimbursement, but in cases where he makes these advances and also furnishes water for irrigation he may collect 50% of the crop. All advances to the tenant must be in cash and must be returned in cash or in grain at the price current in the nearest market. Probably the most important article of the decree provides that in view of the exceedingly low wages heretofore prevailing, all loans and advances heretofore made and now outstanding against the laborers, must be considered as a voluntary supplement to the inadequate wages and are therefore declared liquidated and canceled.

PERSONAL

W. J. Cox was in New York last week.

D'Arcy Weatherbe is on his way to northern Mexico.

Information is wanted concerning Leslie Ramdal Mascarenhas, who left Rossland, B. C., April 12, 1913.

Karl Hoffman sailed from Liverpool on October 7, on the *Baltic*, and will make a short stay in New York.

Lewis F. Johnson has returned to San Francisco from Los Angeles. He went to Sierra county at the end of the week.

Otto von Schlichten, of the Missouri Geological Survey, was married to Miss Anna Erlwein, of Cincinnati, October 21.

F. B. Weeks and G. E. Anderson are in Alaska, and recently examined some quartz properties in the Kantishna field.

Willis Lawrence returned from the Orient on the *Mongolia*, September 15, and has gone to El Dorado, California, on professional business.

A. M. Patterson, editor of *Chemical Abstracts*, has resigned from that position on account of his health. He joined the staff as associate editor in 1908. J. J. Miller will take his place, having been with the publication for five years.

The officers of the Oriental Consolidated Mining Co., operating in Korea, are as follows: Alf. Welhaven, general manager; Thomas W. Van Ess, assistant general manager; C. A. Crispin, auditor; E. S. Barstow, superintendent of transportation; J. B. Lower, superintendent of Tabowie, Taracol, Candlestick, Chintul, and prospects; F. W. Deal, superintendent of Maibong and Kuk San Dong; W. H. Aldridge, mechanical engineer; E. H. Emeason, electrical engineer; J. N. Fletcher, superintendent of fuel and timber railway; A. B. Palmer, cashier; J. A. Vernon, assistant superintendent of Candlestick, Chintul, and prospects; J. W. Nolan, physician, and W. D. Townsend, agent at Chemulpo.

Obituary

William Lofland Dudley, of Nashville, Tennessee, died September 8, 1914, after a sudden stroke of paralysis.

Albert Peterson, of Odda, Norway, lost his life during August, 1914, in a manner not clearly known, since he disappeared from a steamer leaving Odda for Bergen and his body was not recovered.

SCHOOLS AND SOCIETIES

The Cleveland Engineering Society met on October 13, when J. B. Merlam read a paper on 'The Useful Recovery of Heat Losses in Internal-Combustion Engines.'

The Salt Lake City local section of the American Institute of Mining Engineers recently elected the following officers: Robert C. Gemmell, president; Charles W. Whitley, vice-president; and E. Gayford, secretary and treasurer.

The nominating committee of the A. I. M. E. reported the following ticket at the meeting of the Board of Directors, October 23: president, W. L. Saunders; vice-presidents, Sidney J. Jennings, Philip N. Moore; directors, George C. Stone, W. H. Aldridge, Robert W. Hunt, S. A. Taylor, Hennen Jennings.

The Le Conte Geological Club will meet at the University of California, Berkeley, today. The program will include: 'Bogosloff Island,' A. S. Eakle; 'Prospective Oil and Gas Field in Rio Blanco County, Colorado,' J. A. Taff; 'What the Petroleum Department of the State Mining Bureau Is Doing,' C. A. Waring; 'Stratigraphy of the Tesla, Pleasanton, and San Jose Quadrangles,' E. B. Hall.

The American Electrochemical Society held a joint session at Pittsburgh with the local branch of the American Institute of Electrical Engineers on September 22. The electrical precipitation of smoke, dust, etc., was discussed by A. F. Nesbit, of the University of Pittsburgh, while A. F. Weston, of the Research Corporation of New York City, showed lantern slides illustrating applications of the precipitation process. The Niagara Falls meeting of the Society was held on the first days of October, and was an excellent one. The experimental symposium at the Fitzgerald laboratories was an interesting innovation.

The State School of Mines and Metallurgy at El Paso, Texas, announces that the first semester began on September 23 and ends on January 31, 1915. The location of this new institution is first class, being in a city of 60,000 people, an important railroad centre, with great agricultural and irrigation resources near by, and where one of the largest smelters in the world is in operation, receiving a great variety of ores from the Southern and Western states and Mexico. Students have little trouble in gaining admission to the school. Complete courses are given in mining and metallurgy. The college contains a number of fine buildings for all purposes.

In accordance with the agreements for coöperation between the Massachusetts Institute of Technology and Harvard University, fifteen of the Harvard professors are to be added to the instructing staff of the Institute this year. Their names and departments are the following: Mining department—Henry Lloyd Smyth, Edward Dyer Peters, Albert Sauveur, George Sharpe Raymer, and Charles Henry White. Metallurgy—Louis Caryl Graton. Mechanical Engineering—Lionel Simeon Marks, and Arthur Edwin Norton. Civil Engineering—George Fillmore Swain, Lewis Jerome Johnson, Hector James Hughes, and George Chandler Whipple. Electrical Engineering—Arthur Kennelly, Harry Ellsworth Clifford, and Comfort Avery Adams. Four of these gentlemen, Messrs. Swain, Whipple, Sauveur, and Clifford, are M. I. T. graduates.

The U. S. Civil Service Commission announces an open competitive examination for junior explosives engineer, for men only, on November 18. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Bureau of Mines at Pittsburgh, or at other places in the field, at salaries ranging from $1200 to $1500 per year, and vacancies as they may occur in positions requiring similar qualifications. Competitors will be examined in the following subjects: Elementary chemistry and physics; essay relating to one or more of the following subjects: manufacture, transportation, storage, or use of blasting explosives; testing and properties of blasting explosives; precautions to be observed in the testing and use of blasting explosives; and education, training, and experience.

The U. S. Civil Service Commission announces an open competitive examination for aid in mineral technology, for men only, on November 18. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Division of Mineral Technology in the National Museum, Washington, D. C., at a salary of $1200 per year, and vacancies as they may occur in positions requiring similar qualifications, unless service officials are appointed. Competitors will be examined in the following subjects: general geology, elements of chemistry and practical mineralogy, economic geology and mining, metallurgy and applied chemistry of the non-metals, and education and experience.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, October 22.

Antimony	12 —12¾
Electrolytic copper	13 —13¼
Pig lead	3.75—4.70
Quicksilver (flask)	$50
Tin	36 —37½
Spelter	6 — 6¼
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, October 22.—Lead is dull at 3.50c., and spelter firmer at 4.73c. per pound. Gold output of the Rand in September was 702,170 oz. worth £2,982,630, compared with 711,917 oz. and £3,024,037 in August, a decrease due to the shorter month.

'The American Metal Market,' in discussing the effect of the war on the metal market, shows that the situation is as follows: lowest price for 17 years, lead; 10 years, copper; 5 years, tin; and 5 years, spelter.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The steady downward course of prices continues. Silver is now 50c. per oz. in New York, and 22.81d. in London. Samuel Montagu & Co., on October 8, stated that steadiness continued to characterize the market. Interest taken by India and China is light. Exports from London to the East for the year to date show a decrease of £3,256,500, or say 30,000,000 oz. An Indian currency return for the last week in September shows a decrease of 104 lacs of rupees of gold ($3,362,320), compared with the previous week. The rupees decreased $129,320. The 688 bars of silver confiscated in Mexico City by the authorities have been returned to the owners. At the end of last week 280 bars, weighing 318,985 oz., left Cobalt for England.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Oct. 15	3.50	Sept. 2	3.90
" 16	3.50	" 9	3.85
" 17	3.50	" 16	3.85
" 18 Sunday		" 23	3.85
" 19	3.50	" 30	3.75
" 20	3.50	Oct. 14	3.75
" 21	3.50	" 21	3.50

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	4.28	4.11	July	4.35	3.80
Feb.	4.33	4.02	Aug.	4.60	3.86
Mch.	4.32	3.94	Sept.	4.70	3.82
Apr.	4.36	3.86	Oct.	4.37	....
May.	4.34	3.90	Nov.	4.16	....
June	4.33	3.90	Dec.	4.02	....

The low quotations have induced purchases in the East. There is said to have been some curtailment of production, although not general. Prices in St. Louis are firm at 3.37½c. per pound.

COPPER

Prices of electrolytic in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	12.34
Mch.	14.72	14.11	Sept.	16.23	12.02
Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

The September average, like that for August, is the settlement price of ore shipments received by the American Smelting & Refining Co. Electrolytic metal is now quoted at from 11.30 to 11.40c. per pound. Sales have been light, though there were signs of stiffening in prices, resulting from domestic and foreign enquiries. Exports to October 21 totaled 13,154 tons. War risk rates on metal consigned to Italy have advanced to 2% from ¾%. Standard copper in London is £49 per ton, against £56 on July 30.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending		Oct. 8	55.00
Sept. 24	75 00	" 15	55.00
Oct. 1	55.00	" 22	50.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	80.00
Mch.	40.20	39.00	Sept.	39.70	76.25
Apr.	41.00	38.90	Oct.	39.37	....
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

There have been small sales at $47.50 per flask, but the regular price is as above.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
Oct. 15	4.73	Sept. 2	5.75
" 16	4.73	" 9	5.50
" 17	4.73	" 16	5.25
" 18 Sunday		" 23	5.00
" 19	4.73	" 30	4.88
" 20	4.73	Oct. 14	4.55
" 21	4.73	" 21	4.73

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	6.88	5.14	July	5.11	4.75
Feb.	6.13	5.22	Aug.	5.51	5.45
Mch.	5.94	5.12	Sept.	5.55	5.16
Apr.	5.52	4.98	Oct.	5.22	....
May	5.23	4.91	Nov.	5.09	....
June	5.00	4.84	Dec.	5.07	....

St. Louis quotations are 4.70 to 4.75c. per pound, with a strong feeling. Ore producers in the Missouri-Kansas-Oklahoma district are receiving the lowest price since 1908, namely, $32 to $39 per ton for 60% grade. The Butte & Superior mine, Montana, is closed for some time, owing to repairs to the main shaft. This should relieve the supply of concentrate for a time.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

Tin has been down to 28.50c. per pound, but shows signs of an advance. There is a movement on foot to erect a smelter in the East to handle tin concentrate from Bolivia. It is thought that if the American supply of Straits metal is interrupted, the situation would be dangerous.

CYANIDE

Odd lots of a few tons are now available second-hand, and the steamer sent to Rotterdam by the Roessler & Hasslacher Chemical Co. should by now be returning. It was to have loaded October 20. The difficulties as to re-shipment to Mexico have been smoothed out, though there is still no assurance that a supply will be available for Central and South America. After the accumulated surplus in Germany has been brought over, it may be necessary to rely entirely upon domestic manufacture, as operations in Germany are much disturbed. Just how that may result cannot yet be foretold. The Perth Amboy plant can take care of all the mines in the United States. When the Cyanamid company gets into business there should be a surplus available for Latin America. Roessler & Hasslacher company quote sodium and potassium cyanide in their chemical list of October 15 at 25c. per pound.

COMPANY REPORTS

BISMARCK MINING COMPANY

During the year ended July 31, 1914, the Bismarck company, at Flatiron, South Dakota, mined and milled 79,036 tons of ore containing a gross value, by assay, of $114,831 (an average of $1.453 per ton). From January 1 to July 31 the figures were a trifle better; 42,880 tons had a gross assay value of $65,326 (an average of $1.52 per ton), and, of this, $55,113 was recovered. The recovery, made entirely by simple leaching of the dry-crushed product, was $1.285 per ton, equal to an extraction of 84.54%. During this 7-month period the property earned a slight profit; during the remainder of the year it sustained a loss. The costs for the entire year were at an average of $1.253 per ton. This remarkably low cost covers all of the expenditures for mining, including stripping of 25 to 30 ft. of overburden, tramming, milling, and general expenses, on an output of 250 tons per day, and is only comparable in its excellence to the high extraction made in the mill. It apparently indicates good management and close attention to detail. Of the costs, 69.4c. is charged to milling and 55.9c. to mining. The stripping cost 15.18c. per ton of ore mined. During only three months of the year was the mill operated at full capacity, and in that time the lowest costs were recorded, namely, $1.13, $1.125, and $1.09 per ton. In the mill, 0.349 lb. of cyanide was consumed for each ton of ore treated. Zinc consumption amounted to 0.396 lb. per ton, or $33.27 per $1000 of bullion recovered. The property has been closed, and no statement has been made as to possibility of resumption.

ORIENTAL CONSOLIDATED MINING COMPANY

Regular monthly reports of this Company, operating in Korea, are published in this journal, and the one under review covers the year ended June 30, 1914. It consists of 43 pages, replete with tables and an index. The general manager, Alf. Welhaven, reported as follows:

Development in nine mines totaled 32,379 ft., against 33,248 ft. in 1912-13, while there was also 2548 ft. done in prospecting outside of the active mines, making 34,927 ft. in all. Reserves of ore in the various claims is as follows, as at July 1, 1914:

Mine.	Tons.	Value.	Prod., tons.	Value.
Tabowie	500,000	$ 6.10	112,002	$ 7.31
Taracol	255,000	4.65	95,767	5.87
Kuk San Dong (4)	2,500	3.50	22,443	4.82
Charabowie	37,000	8.22	33,552	10.25
East Candlestick	6,000	13.34	7,778	12.70
Chintul	14,000	3.79	29,620	4.39
Total	814,500		301,162	$ 6.85

There is also 8000 tons of $10 ore in the Tongkol mine.

Mining the above tonnage last year cost $1.98 per ton, including all development. The total value of the ore hoisted was $2,062,563. The Tabowie mine is in fine condition, and promises well for the future. A new western orebody was opened on No. 8 and 10 levels. Development in the Taracol was satisfactory, although western extensions were disappointing. Ore-shoots in the Chintul are irregular, but results were fairly good. All development in the Kuk San Dong North, South, Central, and Kisen mine has been stopped, and ore left is confined to pillars. The Charabowie mine is promising. Water from the river has hindered work. Hoisting and pumping here is done by three electric hoists and seven electric pumps. Cost of mining was $3.41, compared with $1.18 to $1.94 in the others, save the Candlestick, where it was $6.69 per ton. The latter mine is opening well. A good deal of prospecting was done at the West Candlestick, Tongkol, Sambong, Chosen claims, and 10 other properties. Korean tributers ran 19 water-power mills in five different places.

Metallurgical results were as follows:

Mill.	Stamps.	Ore, tons.	Bullion, value.	Concentrate saved, tons.
Tabowie	80	112,002	$ 344,313	13,010
Taracol	80	125,387	308,514	10,131
Kuk San Dong	40	22,443	56,734	2,940
Maibong	30	33,552	256,129	1,154
Candlestick	10	7,778	70,378	*7,778
Total	240	301,162	$1,036,068	35,013

*Mill pulp.

The assay offices conducted 39,386 assays. The Taracol tube-mill plant treated 12,856 tons of concentrate, yielding $317,827, with 80.2% recovery. Owing to high cost and low extraction, the leaching method on fresh concentrate was reverted to in February 1914. The Taracol cyanide plant treated 10,285 tons of concentrate, yielding $252,961, with 82.5% recovery. Its extraction was 2.3% higher than the tube-mill plant, and cost $1.63 per ton, against $4.58 in the tube-mill plant. The Kuk San Dong cyanide plant treated 4552 tons of concentrate, yielding $67,353, with 59.1% recovery. This was 5.9% lower than last year. The Kuk San Dong re-treatment plant dealt with 12,646 tons of dump and old untreated concentrate, yielding $59,455, with 63.8% recovery. The cost was $3.18 per ton, or 79c. over last year, due to more refractory ore using more cyanide and zinc. This plant is to be re-erected at the Maibong mill. The Candlestick cyanide plant treated 7778 tons of mill pulp, yielding $14,868, with 52.4% recovery. The average gross and net saving were 90.2 and 81.8%, respectively. Mill tailing averaged 67c. per ton, or $202,356 out of a gross value of $2,062,563.

Financial results were as follows:

Total revenue	$1,731,472
Operating expenses	994,733
Operating profit	$ 736,739
Development and construction	113,959
Net profit ($51,396 over last year)	$ 622,780
Dividends paid (part from previous surplus)	644,780
Surplus on hand	645,702
Supplies on hand at June 30, 1914	356,085

Costs were as follows: mining, $1.98; transport of ore, 1c.; milling, 56c.; concentrate treatment, 32c. ($2.77 per ton treated); and general, 43c.; a total of $3.30 per ton.

Taxes paid to the government-general of Chosen were $26,489. Construction work, $104,282, included electrification of the important Nuchadagi pumping plant, mills' water supply, cottages, head-frame, saw-mills, refinery, electrification of three camps, tube-mill construction, and explosives' magazines, the last in compliance with government regulations.

The wood company supplied 18,130 cords of wood, 194,120 pieces of mining timber, lumber, and lagging, and 4110 boxes of charcoal. The cordwood line is 17 miles long. In reforesting, there were 72,000 acacia trees planted, and the nurseries contain 120,000 seedlings for next year's planting. The cost was $2755.

The hydro-electric plant worked 69½ days, averaging 506 hp. per day. Owing to lack of water, it was closed the remainder of the year. The rainfall was 41.25 in., June supplying 12 in., but at present there is plenty of water.

Bullion from the plants is sent to the Imperial Japanese mint at Osaka. The medical staff treated 26,209 cases, of which 8693 cases were from Company employees. No charge of any kind is made to anybody for service.

MINERAL STATISTICS

The following data, covering the year 1913 is from the U. S. Geological Survey:

Iron Ore in Minnesota

Iron ore mined in Minnesota last year was 34,249,813 long tons, worth $61,805,017, out of the United States total of 59,643,098 tons, valued at $130,905,558.

White Arsenic Consumption

The consumption of white arsenic in the United States in 1913 amounted to about 7200 tons, valued at $570,000, of which 2513 tons, valued at $159,236, was produced in this country as a by-product from copper and precious-metal smelters, and the remainder was imported largely from European countries.

Mineral Production of Ohio

Mineral production of Ohio in 1913 was valued at $121,690,661, an increase from the $111,229,656 of the previous year. Coal and clay are the leading products, the former being 36,200,527 short tons, valued at $39,948,058. The oil yield decreased from 8,969,007 to 8,781,468 bbl., and natural gas from $11,891,299 to $10,416,699. Salt amounted to 5,310,135 bbl., valued at $1,318,156, according to the U. S. Geological Survey.

Asphalt

The production of natural asphalt in 1913 amounted to 92,604 short tons, valued at $750,713, a decrease from 95,166 tons, valued at $865,225, in 1912. The output of manufactured or oil asphalt in 1913 was 436,586 tons, valued at $4,531,657, against 354,344 tons in 1912, valued at $3,755,506. The total quantity of asphalt imported into the United States for consumption in 1913 was 228,178 tons, valued at $910,611. The Island of Trinidad furnished the greater part of this, namely, 125,273 short tons.

Bauxite in Arkansas

Arkansas is first among the states in the production of two minerals, bauxite and novaculite, the former being the ore of aluminum and the latter the source of the larger part of the oilstones produced in the United States. The principal mineral product of Arkansas, however, is coal, the annual value of which constituted over 50% of the state's total. The total value of all mineral products of Arkansas in 1913 was $6,780,760, compared with $6,258,726 in 1912. The coal production was 2,234,107 short tons, valued at $3,923,701 in 1913, against 2,100,819 tons, valued at $3,582,789, in 1912.

Phosphate Rock in Florida

Florida lays claim to importance as a mineral producing state by reason of the exploitation of its phosphate resources, ranking first among all the states in the quantity and value of its production of phosphate rock, which represents 90% of the value of the state's total mineral output. In 1913 the output amounted to 2,545,276 long tons, valued at $9,563,084, against 2,406,899 tons, valued at $9,461,297, in 1912. Land pebble constitutes approximately 80% of the total quantity produced, but only about two-thirds of the total value. Hard rock is generally of higher grade than pebble and brings about twice as much per ton to the producers. This state also produces 70% of the total United States output of fuller's earth.

Mineral Production of Kentucky

The principal mineral product of Kentucky is coal, the value of which constitutes about three-fourths of the value of the state's total mineral output. In 1913, the total value of the mineral production of Kentucky was about $27,000,000, of which the coal mines contributed $20,516,749. This is an increase of about $4,500,000 in value of total mineral products over the figures for 1912. The second industry in importance, clay-working, contributed $2,914,276 in 1913, an increase of $470,536 over 1912. The quarrying industry is third, its products in 1913 being valued at $1,150,205, against $1,282,148 in 1912.

Lead and Zinc in Missouri

Missouri leads all the other states in the production of lead and zinc, and barytes and tripoli. The total value of the lead and zinc concentrates sold in 1913 was $21,109,358, against $24,937,161 in 1912. Based on the metallic content, the total production of lead and zinc in Missouri in 1913 was valued at $29,494,064, against $34,820,248 in 1912. The decrease in 1913 was almost entirely due to a smaller output of zinc ores, with a marked decline in price. Third in importance among Missouri's mineral industries is the mining of coal, the production of which decreased slightly, from 4,339,856 short tons, valued at $7,633,864, in 1912, to 4,318,125 tons, valued at $7,468,308, in 1913. The total value of the clay products increased from $6,412,861 in 1912 to $6,602,076 in 1913. In addition to the manufacture of clay products, the raw clay mined and sold in 1913 amounted to 238,032 short tons, valued at $470,277. The production of portland cement, which ranks fifth among Missouri's mining industries, decreased from 4,614,547 bbl. in 1912 to 4,485,820 bbl. in 1913, but increased in value from $3,700,766 to $4,556,822. The quarry products, principally limestone, exhibited a slight increase, showing $2,538,699 in 1913, against $2,486,505 in 1912. The sand and gravel pits yielded 4,126,126 short tons in 1913, valued at $1,109,233, against 3,687,380 tons, valued at $1,088,279, in 1912. The production of lime increased from 148,885 short tons, valued at $721,896, in 1912 to 161,770 tons, valued at $734,009, in 1913. On account of the decreased value of the zinc production in 1913, the total value of the mineral products decreased from $58,332,550 in 1912 to $54,001,008 in 1913.

Mineral Production of Pennsylvania

Pennsylvania so far exceeds all the rest of the states in the value of its mineral products as to stand almost alone. Exclusive of the value of pig iron, coke, and other derived or secondary products not included in the total, the value of Pennsylvania's mineral production is nearly one-fourth that of the entire country. Although not an iron-ore state, Pennsylvania is by far the leading producer of pig iron, which is obtained from the Lake Superior ores. The production in 1913 was 12,871,349 long tons, valued at $197,726,314. If the value of the pig iron made in Pennsylvania were added to the value of the other products of the state, the total values for 1913 would have exceeded $700,000,000, which is more than one-fourth of the value of the total mineral production of the United States. The production of coal in Pennsylvania in 1912 amounted to 246,227,086 short tons, valued at $346,993,123; in 1913 the value was $388,220,933, an increase of $41,227,810, or 12%, over 1912. Second in importance among Pennsylvania's mineral industries is the manufacture of portland cement, closely followed by the clay-working industry. The production of cement in 1913 was 28,060,495 bbl., valued at $24,268,800, against 27,625,340 bbl., valued at $18,945,835, in 1912. The value of clay products, exclusive of raw clay mined and sold, increased from $21,537,221 in 1912 to $24,231,482 in 1913. The value of the natural gas produced increased from $18,539,672 in 1912 to $21,695,845 in 1913. The output of petroleum increased slightly in quantity, from 7,837,948 bbl. in 1912 to 7,963,282 bbl. in 1913, with an increase of over 50% in value, from $12,886,752 to $19,805,452. The production of limestone is the principal factor in placing Pennsylvania first as a producer of stone, though the state is also first in the production of slate, sand and gravel, and lime. In 1913 the total value of the stone quarried in Pennsylvania, exclusive of slate and of limestone made into lime, was $10,117,469, against $9,144,214 in 1912.

RECENT PUBLICATIONS

Ore Deposition in and Near Intrusive Rocks by Meteoric Waters. By Andrew C. Lawson. P. 23. Ill. University of California, Berkeley.

On a Probable Eighth Fragment of the Gloaieta Meteorite. By Richard C. Hills. Reprint from *Proceedings* of the Colorado Scientific Society. P. 4 and 4 plates.

Relative Resistance of Various Conifers to Injection with Creosote. By C. H. Teesdale. *Professional Paper* 101. P. 43. Ill. U. S. Department of Agriculture, Washington, D. C., 1914.

The Diaphragm Method for the Measurement of Water in Open Channels of Uniform Cross-Section. By Carl Robert Weidner. *Bulletin* 672. P. 72. Ill., plans, tables. University of Wisconsin. Madison, 1914.

Labor Laws of the United States, with Decisions of Courts Relating Thereto. Part II. *Bulletin* 148. P. 1256. U. S. Department of Labor, Bureau of Labor Statistics, Washington, D. C., 1914. A comprehensive work which should be in the hands of all employers of labor.

A Geologic and Microscopic Study of a Magmatic Copper Sulphide Deposit in Plumas County, California, and Its Modification by Ascending Secondary Enrichment. By H. W. Turner and A. F. Rogers. Reprint from *Economic Geology*. P. 33. Illustrated. An abstract of this paper was printed in the *Press* of July 4, 1914.

The Deep Boring at Spur. By J. A. Udden. *Bulletin* 363 of the University of Texas. P. 105. Ill., 12 plates, plan, index. Austin, October, 1914. For the purpose of finding water for the town of Spur, a well was drilled 4489 ft. at a cost of approximately $50,000. A fine geological record waa kept of the country passed through by the driller, H. P. Minihan.

Department of Mines, Ottawa, Canada, publications, 1913 and 1914:

The Copper Smelting Industries of Canada. By Alfred W. G. Wilson. P. 184. Ill, 5 plates, maps, plans, index. This is a valuable contribution to copper smelting practice, and an abstract will appear in another issue of the *Press*.

Lode Mining in Yukon. An investigation of quartz deposits in the Klondike division. By T. A. MacLean. P. 212. Ill., maps, plans, index. An abstract of this work, which should be owned by all interested in the Yukon, was published in the *Press* of October 17.

Preston County, West Virginia. By Ray V. Hennen and David B. Reger. Part IV. Paleontology, by W. Armstrong Price. P. 566. Ill., index, and case of maps. Wheeling, 1911. In addition to the detailed description of all the geologic formations exposed in Preston county, the geologic map gives the structural contours and outcrop of the Upper Freeport coal, the most important mineral horizon of the area in question. The soil and topographic maps will also prove of great value to every interest including agriculture, road improvement, water resources, etc. Price, with case of maps, delivered charges paid by the West Virginia Geological Survey, $2.

Thermal Properties of Steam. By G. A. Goodenough. *Bulletin* 75. P. 69. Ill. University of Illinois, Urbana, 1914. The bulletin presents a critical discussion of the experimental investigations of the various thermal properties of steam, an outline of the thermodynamic relations that must be satisfied, and finally, the development of a general theory of superheated and saturated steam. As a basis for such a theory the well known Munich experiments on specific volumes and specific heats are taken and properly correlated through the Clausius relation. The result of the investigation is a formulation of the properties of steam for which the following claims may be urged: (1) absolute thermodynamic consistence; (2) extreme accuracy; (3) simplicity; (4) flexibility; and (5) great range of validity.

Proceedings of the Australasian Institute of Mining Engineers. May meeting. P. 402, ill., plans, maps. Melbourne, Victoria. Contains the presidential address of H. Herman on 'Mining, Other Industries, and Gambling;' 'The Long Tunnel Incline and Vertical Shaft, Walhalla, Victoria,' by J. Finlayson; 'Victorian State Coal mine, Wanthaggi,' notes on development, organization, etc., by George H. Broome; 'Geology of the State Coal Mine,' by Stanley Hunter and Leslie Owen; 'Core-Drills at the State Coal Mine,' by Stanley Hunter; 'Practical Underground Work at the State Coal Mine,' by John M'Leish; 'The Electrical Installation at the State Coal Mine,' by Struan S. D. Robertson; and 'Australian Tin Lodes and Tin Mills,' by H. Herman. Abstracts from these interesting papers will appear in the *Press* from time to time.

The Explosibility of Grain Dust. A preliminary report by David J. Price and Harold H. Brown. P. 59. Ill. Pittsburgh, 1914. As a result of a number of explosions in grain mills and industrial plants in this country and in Europe, and more especially as a result of an explosion in a feed-grinding plant at Buffalo, in June 1913, by which 33 men lost their lives and upward of 70 were injured, a coöperative movement between milling interests generally and the U. S. Bureau of Mines was arranged for the purpose of making a scientific study of the explosibility of grain dusts, and of methods pertaining to the prevention of such explosions. Since 1905 there have been 13 explosions, killing 78 and injuring 119, and damaging property amounting to $2,000,000.

New Machines and Devices

Largest Diesel Engine Built in Ame ica

The Lyons Atlas Co., of Indianapolis, Indiana, has recently completed and shipped the largest Diesel engine constructed to date in this country. This engine is composed of four cylinders, 21-in. bore by 30-in. stroke, and is of the vertical four-cycle type, rated at 600 brake horse-power, with an overload capacity of 15%, or 690 b.hp. maximum. It was sold to the Hawaiian Commercial & Sugar Co., and is intended to supersede a steam plant for irrigation purposes, to be direct connected to a two-stage turbine pump of 15,000,000 gal. capacity at 200 ft. head. The purchaser insisted that the engine should operate continuously 710 out of each 720 hours per month at rated load, using the ordinary 14 to 18° asphaltum base California fuel oil, similar to that used in the purchaser's steam plant, and which is the only grade available on the Islands. The test was conducted by the chief engineer of the sugar company, and the engine was given a preliminary continuous run of 48 hours with Eastern paraffin-base fuel, after which all parts connected with the combustion chambers were inspected in order to determine a basis for comparison between the effect of the two fuels. It was then subjected to a 144-hour continuous run at full load with fuel shipped by the purchaser from California to the manufacturer's works. At the completion of this run the combustion chambers were again examined, and as there was no evidence of deposit on the heads, valves, or pistons, the engine was accepted and is now en route to the Islands, to be erected without any assistance from the manufacturer.

A Portable Motor-Operated Compressor

The Sullivan Machinery Co. manufactures a small motor-driven air-compressor which is designed for use in mines and industrial plants, for supplying air for rock-drills, hammer drills, pneumatic tools, coal pick machines, and post punchers. The complete unit is mounted on a truck of any desired gage and comprises a 15-hp. Westinghouse motor, the air-compressor, a storage tank, and a motor-starting rheostat.

The motor is of the damp-proof type and will operate successfully in the wettest mines. It is supplied for either alternating or direct current. The receiver is made of plate steel and is tested to withstand 100 lb. air pressure. With it are furnished a pop safety valve, pressure gauge, and drain cock. The construction of the air-compressor is very substantial. The bearings are all adjustable and removable. The cylinder is lubricated by a sight feed air-cylinder lubricator, and the crank-shaft and crosshead by the splash system. An unloading device on the air-inlet valves saves energy when the demand for air is less than the output of the machine.

Commercial Paragraphs

The Charles C. Moore Co. has sold through its Seattle office to the Carbon Hill Coal Co. one 6-in. 6-stage Platt Iron Works centrifugal pump.

The B. F. Goodrich Co. recently shipped 18 tons of belting, nearly one mile, upon receipt of a cable order from abroad. The Goodrich company now manufactures about five miles of rubber belting per day and has regularly 15 miles in process and 50 miles under order.

The Tropenas Converter Co. issues a little journal called *Steel Castings*, in the October number of which is reprinted an article by G. Muntz on 'Tropenas Converters r. Electric Furnaces for the Manufacture of Steel Castings,' from *Met. & Chem. Eng.* The Tropenas converter is one in which the air is blown between the slag and the metal. It has established an enviable reputation for reliability.

The Link-Belt Co. announces receipt of an order from the United States government for four steam-operated revolving cranes, three of which will be used at the Philadelphia Navy Yard, and the fourth at Charleston. These cranes are all of the standard eight-wheel type with slight modifications to conform to government specifications. The Link-Belt Co. has just issued a new 'Locomotive Crane Book,' No. 158 which illustrates excellently the different types of cranes made by the Company and the wide variety of uses to which they are applied.

The Sullivan Machinery Co., Chicago, *Bulletin* 66-H, describes Sullivan rock drills, especially 'Liteweight' and 'Hy-Speed' machines. Every part of these drills is illustrated and described. Both are fitted with Sullivan automatic lubricators, oiling having been a problem to all drill manufacturers. The characteristic feature of the 'Hy-Speed' is the valve-motion, a combination of the differential or pressure-thrown and piston-thrown or tappet patterns, in which the advantages of each are retained. The 'Litewelght' weighs 162 lb., and will drill nine feet. A lot of interesting data is given on drill steel suitable for these machines.

'Nascent Engineering Phases in the Iron and Steel Industries' is the title of a most attractive booklet prepared and distributed by the Wellman-Seaver-Morgan Co. It consists of a series of reprints of articles published in *Metallurgical & Chemical Engineering*. The list includes: Recovery of By-Products in the Modern By-Product Coke Oven Plant; A New Pulverized Coal Burner; Handling the Raw Materials at the Iron Blast-Furnace; The Heat Balance of the Open Hearth; A New Electric Steel Casting Plant; Essentials in the Making of the Finer Steel Sheets; the Manufacture of Chilled Iron Car Wheels; Steel for Electrical Purposes. It shows how intimately this firm is concerned with modern metallurgy that the series of articles includes repeated references to machinery made by the Wellman-Seaver-Morgan Co. Indeed, the articles could not be written without reference.

The Lane Mill & Machinery Co., Los Angeles, California, has published an attractive catalogue, which is descriptive of the many products of this well known Company. The catalogue is the seventh edition and contains many new features not to be found in the old edition of 1911. While no radical changes have been made in the construction of the mills, a few minor changes have been made in the construction of the Model 1914 mills which will undoubtedly be beneficial; the tires have been increased in thickness, some parts have been made heavier, the number of separate pieces has been reduced by combining some of them into a single casting, and a few parts are now made of cast iron, which were formerly made of channel or angle iron. The Company has stated plainly and fully the way in which the Lane mill does its work, how it is constructed, its adaptability for different kinds of treatment, and its claims for superiority. The catalogue is fully illustrated and contains a number of plans and specifications of milling plants in which the Lane mill is being used.

IT is with profound regret that we record the recent disaster at the Mitchell coal mine near Royaltown, Illinois. The death of about fifty miners in the performance of their tasks underground is, indeed, a severe shock to the industry, and our deepest sympathy is extended to this grief stricken community.

A CORRESPONDENCE COURSE in the microscopic study of minerals and rocks is being conducted under the auspices of the extension division of the University of Wisconsin. This method of extending the usefulness of the class-room to the mineralogist in the field is most commendable, and we wish Mr. A. N. Winchell every success in this new educational experiment.

STATE MINING BUREAU during the past year has directed an exhaustive investigation of the California oil industry. The need of legislation in regard to the water trouble in the oil sands has been given particular attention and the Bureau has placed itself in the position of a clearing house for ideas as to the nature of the proposed legislation. Every effort is being made to construct a bill which will be fair to both large and small operators, and it is believed that it will have the unanimous support of the oil producers when the next legislature meets.

WESTERN AUSTRALIA'S gold production shows a decline of 44,114 ounces for the first eight months of the present year, as compared with the same period of the previous year. This shrinkage may be attributed to the stoppage of ore treatment at the Victorious, the closing of the Ivanhoe plant for several weeks because of the fire which occurred last February; suspension of operations at the Yuanmi because union labor forcibly objected to contract work; cessation of operations at the Great Fingall while the deep workings were being put in order; and the decline in the Bullfinch output caused by a 'creep' cutting off the supply of good ore and compelling the Company to mine a lower grade of ore. It is anticipated that the production for the remaining four months of the year will be better, as the Ivanhoe, Yuanmi, and Fingall are again in normal condition. The resumption of work at the Edna May, Central, and Beira Consols, lends a feeling of optimism as to the future.

THE return of *The Mexican Mining Journal* to our exchange table after six months suspension of publication is another indication of renewed activity in Mexican mines. These have been stormy days in the Italy of the Occident, but we trust that the rattle of musketry is about to be replaced by the roar of the stamp and rumble of the tube-mill.

THAT field men of the United States Geological Survey are supplied with identification cards bearing their photographs is worth knowing at times. Recent frauds perpetrated by an individual posing as an engineer in this department of the government's service has awakened at least one community to the fact that cashing checks and giving credit on say so alone is sometimes costly.

INSTITUTO MEXICANO DE MINAS Y METALURGIA is to be congratulated upon the publication of Volume III of the *Transactions*, which is at the disposal of members and associates at the Institute's headquarters at 1*a* Calle Independencia 8, Mexico City, or will be mailed upon application to the secretary. Owing to the absence from Mexico of a large part of the members, it was not deemed advisable to hold the annual meeting of the Society in August as provided for in the constitution, and it was resolved in council to continue in office the present incumbents until a more representative attendance is possible. Owing to the death of the secretary and absence from Mexico of the treasurer, the council has appointed J. B. Empson and H. M. Dieffenbach to the offices of secretary and treasurer *pro tempore*.

OPTIMISM as to the country's business outlook is the prevailing sentiment among those in closest touch with the financial situation. It is encouraging to quote Mr. Charles S. Hamlin, the governor of the new Federal Reserve Board, that "while bankers and business men were utterly at sea for at least a month or more after the war started, there is at present a manifest disposition on the part of both banker and business man to discount the future and go ahead. This attitude represents a distinct advance and a speedy reestablishment of full and mutually expressed confidence. Credit will then follow automatically." Mr. Arthur Reynolds, president of the American Bankers Associ-

ation, states that "the situation is getting better each week; the relief measures have been well planned and well executed, and the need now is for conservatism and careful, deliberate work in the direction of strengthening the weak spots. Never have the problems been as serious or as complex as those of the past three months, and no one knows but those who have been in touch with affairs and on the inside what the difficulties of the situation have been. I am thankful to say that the brighter days are ahead, and that before long we shall have clear sailing again." The return to normal conditions is reflected in the report of the New York clearing house, which on October 17 announced that the banks had made good their deficit in required cash reserves, which shortage had existed since August 8 last. The maximum deficit during this period was $43,389,250. During the panic of 1907 the banks reported a deficit for eleven consecutive weeks, the greatest being $54,103,000. Figures in the nation's business point to a restoration of confidence as to what the future holds in store, and pessimism is giving way to the utopist.

METALLURGY of the California Mother Lode ore mined in Amador county has, in the past, been of an extremely simple character, due to the free-milling class of ore mined. From the Hardenburg to the Fremont mine, a distance of about nine miles, there are ten mills of importance with 480 stamps, of which there are now about 360 in operation. Practice until recently has been as follows: Stamps of an average weight of about 950 pounds, with a 6-inch drop, falling 95 to 104 times per minute, crushed from 4 to 5 tons of the friable quartz ore through 20-mesh screens. Inside and outside amalgamation has recovered about 70 per cent of the gold. Then the pulp was diverted to two or three Frue vanners per battery of five stamps, without, save in one instance, any classification. Mother Lode millmen excel in the art of concentration, and from the vanners and other apparatus another 15 per cent of the metal content was saved. The concentrate was generally shipped to smelters. The extraction, therefore, has been about 85 per cent from ore which averaged $4.64 per ton in 1913. On account of graphite in the ore, cyanidation of the tailing from the mills has not been a decided success, and the process has remained one of amalgamation and concentration. The metallurgy of the district was described by Mr. M. W. von Bernewitz in the *Press* of January 3, 1914. On page 670 of this issue, we present a description and discussion of the new mill of the Plymouth Consolidated Gold Mines, Limited, at Plymouth, twelve miles from Jackson, by Mr. Gelasio Caetani, who designed and supervised its erection. A study of this article will show radical improvements in this new mill over those briefly described above, the improvements being mechanical rather than metallurgical. In short, the mill consists of a No. 5 Gates gyratory crusher, an ore-bin of large reserve capacity, thirty 1250-pound stamps with 7-inch drop and 104 drops per minute, 4-mesh screens, two Hardinge mills fed from classifiers, amalgamation, Wilfley tables, and Isbell vanners, and either the smelting or local cyanidation of the concentrate. Against the 4 to 5 tons per stamp crushed in other mills in the county, the Plymouth stamps reduce from 11 to 14 tons each per day. The total recovery has also been increased, and is approximately 90 per cent. While Amador mills have done good work in the past, results at the new Plymouth mill show that improvements are possible. That operations at the Plymouth are proving a valuable object lesson is evidenced by the fact that Hardinge mills are to be installed at the Original Amador mill.

PEACE PROSPECTS IN MEXICO

One traveling through northern and central Mexico at the present time, that country included in the states of Chihuahua, Coahuila, Durango, Nueva Leon, Guanajuato, San Luis Potosi, and Zacatecas, cannot fail but be impressed with what the *Ejercito Constitucionalista,* personified in Francisco Villa, has accomplished toward maintaining peace in this part of Mexico. Whether this influence is destined to be of a lasting nature and the present state of quiescence is the forerunner of a permanent peace or the lull between revolutions, remains to be seen; but for the present there is peace, and there is reason to believe that this part of Mexico at least will continue to be free of revolutions as long as 'Pancho' Villa is at the head of the 'Division of the North.'

When leaving Jiménez for the Aguascalientes convention in the early part of the present month, Villa stated emphatically that the miners could go back to work with the assurance that there would be no more war in Mexico, the lines of transportation would be kept open, and property rights of the foreigners would be respected in the future as in the past. As he was mobilizing the Constitutionalist army in the vicinity of Zacatecas and Aguascalientes at the time, the inference was that while he anticipated an amicable settlement of his differences with Carranza, if there was to be further trouble it would not be carried into this north and central country again.

Peace must be maintained in this country if Villa is to hold together the Constitutionalist army and preserve his present organization. His chief source of revenue being from the customs, mines, and railways, he is making every effort to stimulate a revival in business. True, he has other sources of revenue: street-car lines, hotels, foundries, machine-shops, soap and candle factories, city property, large country estates, and mines which, as prizes of war, the Constitutionalist government has confiscated from the former *scientificos* and their government; but to hold his army intact and preserve his present position, Villa must have funds, and to have adequate funds to meet the requirements of an army of 60,000 and the elaborate organization of the Constitutionalist administration, he must have peace. As a result, Villa has maintained peace in all country taken

by Constitutionalist arms, and he tells us that he will continue to do so.

Mitigating against peace is the present Villa-Carranza trouble arising out of Carranza's alleged violation of the San Luis agreement. There have been so many misstatements published regarding the present controversy, that a brief summary may be in order. At the outset of the recent revolt against Victoriano Huerta to oust the dictator, whose party was held directly responsible for the murder of Francisco Madero; Villa, Carranza, and the chiefs of the so-called Constitutionalist army met at San Luis Potosi and signed an agreement and manifesto stating their reasons for the call to arms, the purpose of the revolution, and made certain guarantees to the people as to future policy when victory came to the Constitutionalist army. This agreement included, among other things, a solution of the agrarian problem, and Carranza was agreed upon as supreme chief of the Constitutionalist cause, and as such would be chief executive until a regular election could be held. At this time it was agreed that no military chief would present himself as a candidate for the presidency, but that someone from civil life and in accord with the Constitutionalist policies would be nominated as their candidate for election. The consensus of opinion is that a member of the Madero family would be the Constitutionalist candidate. Carranza, Villa claims, since taking up the reins of office in Mexico City, has violated his agreement with the people formulated in the plan of San Luis. In addition to proposing an unsatisfactory solution of the agrarian problem, he is claimed to have announced his intention of resigning his office as chief of the Constitutionalist army in order, by this technicality, to conform with the plan of San Luis and become himself a candidate for the presidency. Realizing that Villa, and what he represented, was the chief obstruction in his path for such a political campaign, Carranza, it is claimed by the people of the north, has antagonized and discredited his former ally in every way possible. One instance of this was the appointment of a friend, who had taken no part in the driving of federal authority out of Sonora, to the post of governor, to succeed Maytoreña, the Constitutionalist chief who had been so active against the Huerta administration in that state. This was considered an insult to the Villa party, and has resulted in the resumption of arms by Maytoreña against Gen. Benjamin Hill and his Carranza followers at Naco. He has, according to Villa and his constituents, forgotten his pledges and promises to those who fought his battles, and has devoted his attention since assuming the temporary presidency of the Republic, to strengthening his personal position by attempts to weaken the prestige of the Constitutionalist chiefs. These and many other unfriendly acts to Villa and his former allies have resulted in Villa's proclamation to the Mexican people that Carranza has shown himself unfit to govern, and therefore must go. Like Huerta, having partaken of the presidential prerogatives and found them good, he is loath to pass this high office on to another, even though necessary for the national peace.

While there is a great deal of skepticism as to what will be the final outcome of the Aguascalientes meeting, there is a general and growing public sentiment among the Mexican people against a continuance of this internal strife which has kept the country in a state of turmoil for the past three years, and all classes are hopeful of a peaceful solution. This feeling will undoubtedly have an influence in the present conference and help toward the peaceful settlement of the present difficulty. The time is ripe in Mexico for casting aside selfish and personal ambitions, which have been the underlying cause of all of Mexico's troubles, and pulling together for the common good. The passing of Diaz and Huerta has demonstrated that Mexico will not submit to the administration of a political oligarchy or dictator. The government which shall be a lasting one and bring the much desired peace to Mexico must be constituted for and by the people.

THE AMERICAN COMMITTEE

A recent report of the American committee of London which has been performing such laudable service in the relief of American citizens in Europe who were in need of help due to the contingencies arising out of the European war, is evidence of the magnitude and helpfulness of the work being done in London. Many of the refugees arriving in England have been destitute even in the matter of food; and lodgings have been supplied to more than 5300 Americans. Over 9000 Americans were assisted financially between August 4 and September 26. By subscriptions, temporary loans, and Congressional appropriation, the committee has been able to help to the extent of about $400,000.

While a great good has already been accomplished, the situation has by no means been cleared, and every day brings appeals to the committee from deserving Americans who are in absolute distress. A large number of American families in Europe, which have been supported by their connection with the American export trade, are in great difficulties and dependent upon our own citizens for help, with the result that the resources of the committee are being taxed to the utmost. In addition to relieving the destitute, sub-committees have been selected from those who have volunteered their help, and an invaluable service is being rendered; more adequate shipping facilities are being provided; accommodations have been improved; speculation in tickets has been eliminated; information bureaus have been established, and the care-worn refugee has been helped in innumerable ways. This relief-work must be kept up throughout the war, and further sums are needed for this purpose.

The work of the committee is well worthy of the support of those Americans who are safe at home, and those wishing to help in this Good Samaritan work may do so through the Treasurer of the American Committee in London, 123 Victoria street, London, S.W., or the New York Trust Company, 25 Broad street, New York City.

THE PLYMOUTH MILL.

The Design of the Plymouth Mill

By GELASIO CAETANI

The new 30-stamp mill of the Plymouth Consolidated Gold Mines, Ltd., in Amador county, California, was started on the first of August. The general design and flow-sheet of this mill is different from that of the standard Mother Lode mills and has therefore been much criticized and discussed; it represents an attempt to introduce more up-to-date methods in a district where for more than thirty years there has been no deviation from the traditional practice of direct stamping through fine screens, inside amalgamation, outside plates, and concentration on Frue vanners without any classification.

The flow-sheet of the Plymouth mill is given in Fig. 1, and a cross-section in Fig. 2. The ore is stamped through four-mesh screens; the coarse material is reground by Hardinge mills, and after amalgamation the coarse sand is separated by classification, concentrated on Wilfley tables, and returned to the Hardinge mill for further grinding. The fine sand and slime is concentrated on Isbell vanners.

The differences between this and the standard Mother Lode plant are more mechanical than metallurgical. Though the general aspect of the Plymouth mill is very different from that of the other mills in the district, the metallurgical treatment of the ore is substantially the same. A detailed description of the plant would not therefore be of any special interest, and I will limit myself to a few critical remarks that may be of greater advantage to the reader than a verbose description.

Crusher

The ore from the mine is fed to a No. 5 Gates gyratory crusher. The ore (a typical Mother Lode ore) is very friable, and, in stoping, a large percentage of it breaks up into 'fines.' There is a good deal of clay in the ore, and this comes from the mine in large pasty chunks. In consideration of this, it has been found advisable:

1. Not to use grizzlies ahead of the crusher, but to feed both the coarse and fine ore to the crusher.
2. To run the crusher at about half the speed specified by the manufacturers.
3. To run the crusher under choked feed.

The reasons for doing so are:

1. The use of grizzlies would give an irregular feed to the belt-conveyor which removes the ore from the crusher to the mill.
2. At times the percentage of 'fines' is so great that most of the ore would fall through the grizzlies and overload the belt.
3. The ore is so soft that the crusher does but little work even when buried under the ore. The ore will pass through the crusher about as fast as the swinging of the head allows it to fall through. It can be said, therefore, that the Gates acts as a feeder to the conveyor-belt.
4. If the crusher was run at full speed, it would not be possible to use a choked feed, as the capacity of the crusher would then be in excess of the capacity of the belt-conveyor.

Belt-Conveyor

The conveyor carries the ore for a horizontal distance of 631 ft. and elevates it about 108 ft.; the slope varies from the horizontal to a maximum of 20°30′. It is built in two parts of about equal length. On top of the mill-bins, the ore is dumped on a third conveyor, which distributes the ore by means of an automatic traveling tripper.

The data on this conveyor are:

Belt, 18-in. Manhattan, 5-7 ply, 'Lamina' construction.
Estimated life, three to four years.
Speed, 200 ft. per minute.
Capacity, 50 tons per hour at full load.
Power (approximate averages) for 1510 ft. of belt; one tripper; three head gear and three motors, no load: 16 hp. Same, with crusher loaded at full capacity, 28 horse-power.
Spacing of troughing idlers, 4 feet.

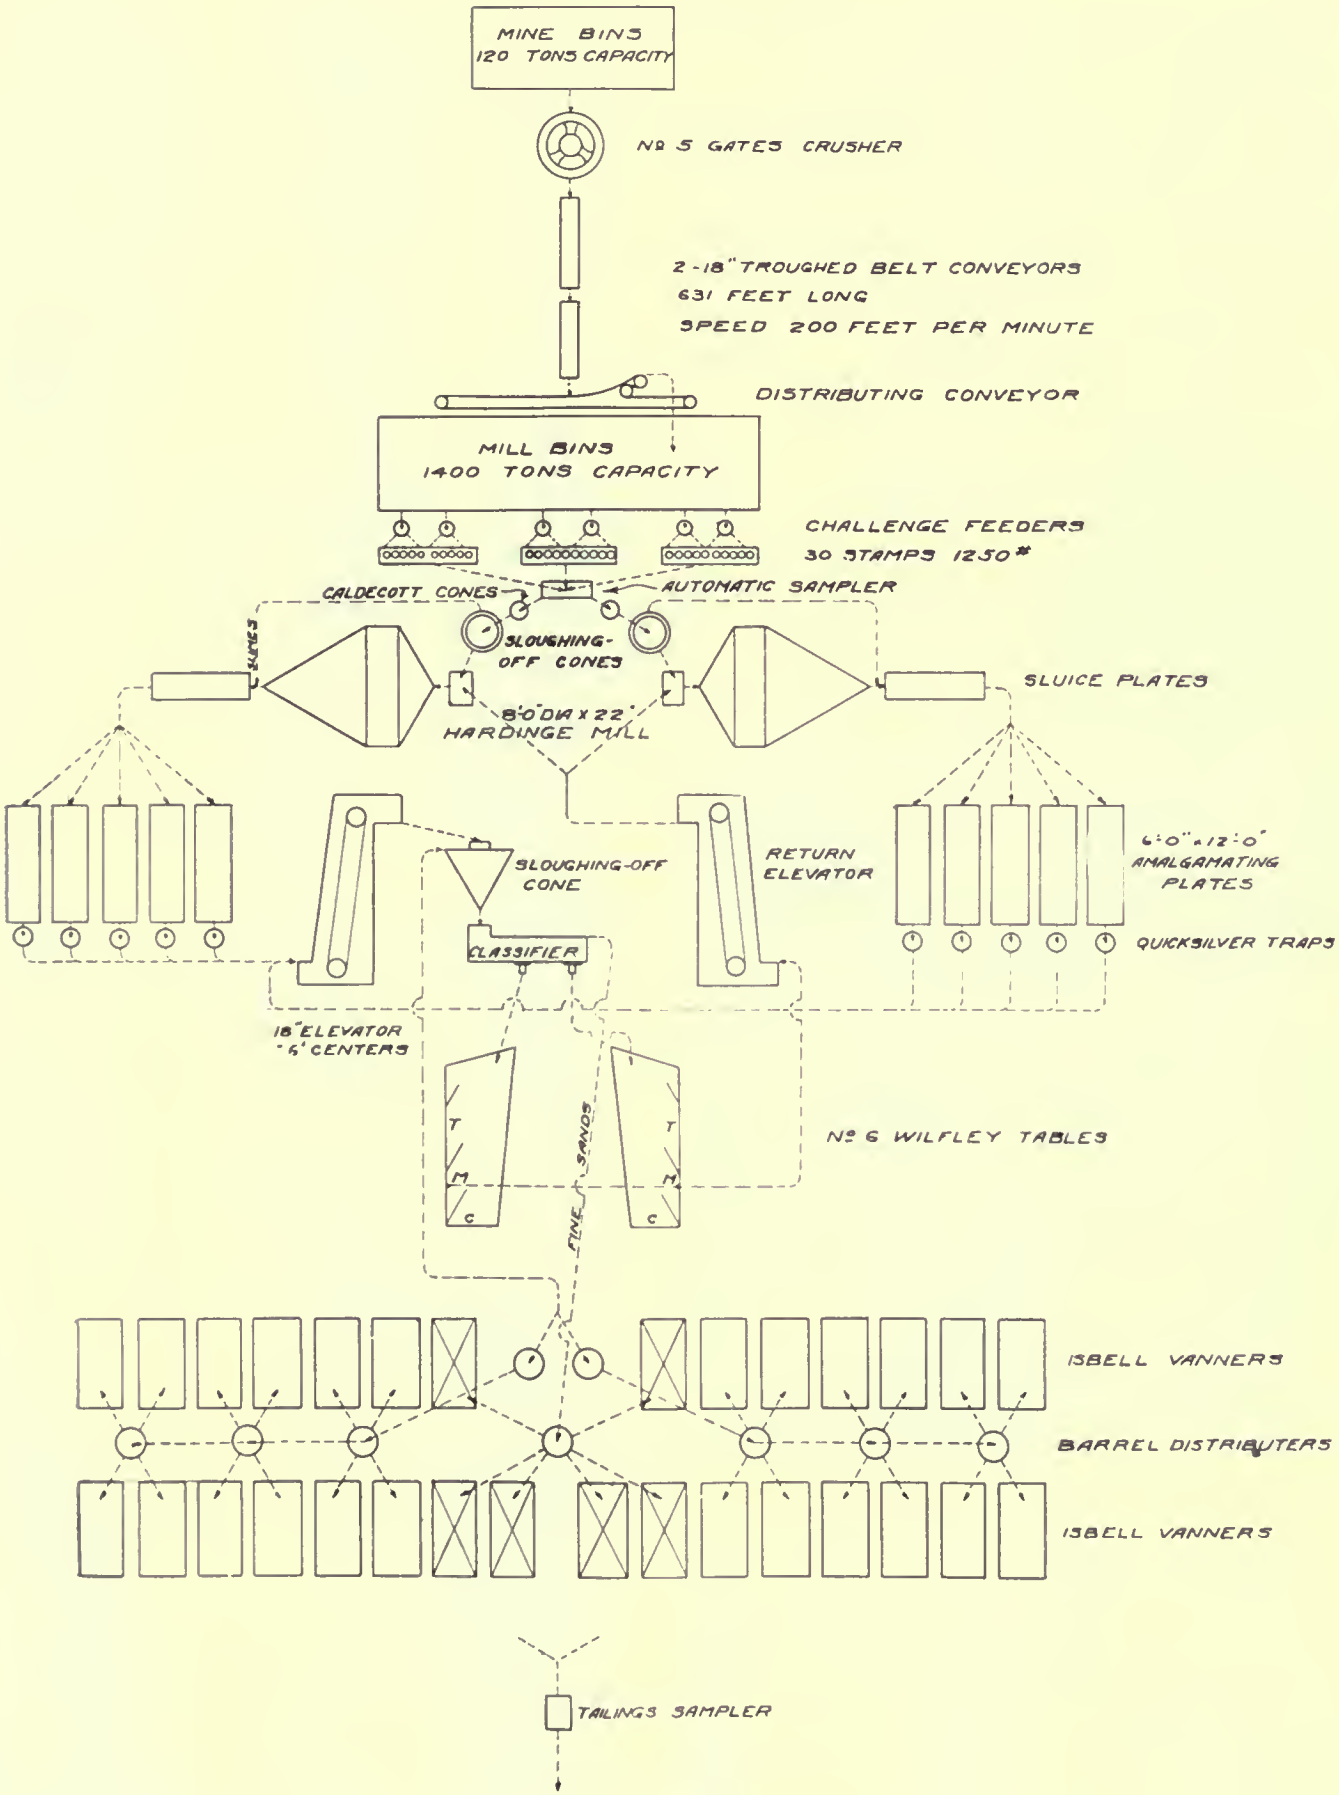

FIG. 1. FLOW-SHEET OF PLYMOUTH MILL.

Spacing of return idlers, 10 feet.
Spacing of upper guide idlers, 50 feet.
Lower guide idlers placed 18 ft. ahead of tail pulley and at every point where the belt changes inclination.
Head pulley, 36 in. diameter, lagged with rubber.

The erection and operation of the conveyors has brought forth the following facts.

Idlers.—The troughing idlers should be tilted forward; this will cause the belt to centre itself. The troughing idlers could be spaced 4 ft. 6 in. instead of 4 ft. Neither upper nor lower guide idlers should be placed half way between carrying idlers, but always as close as possible to one of these. The reason is that close to a carrying idler, the belt is held steadily in place and will run true against the guide idler, whereas in the middle of a span it is sufficiently loose to be able to climb over or under the guide idler pulley when tending to creep out of alignment.

Belt.—The belt should be of first-class quality; it is cheaper. The rubber cover should stand an elongation of 3½ times its original length without breaking. If of good quality, it can be made 400 ft. long between centres unless the slope be very steep. A belt new from the factory is usually covered with a talcous dust. This must be removed by washing before starting up, as it will cause the belt to run off in every conceivable direction. No. 18 Bristol lacing is used, and has proved to

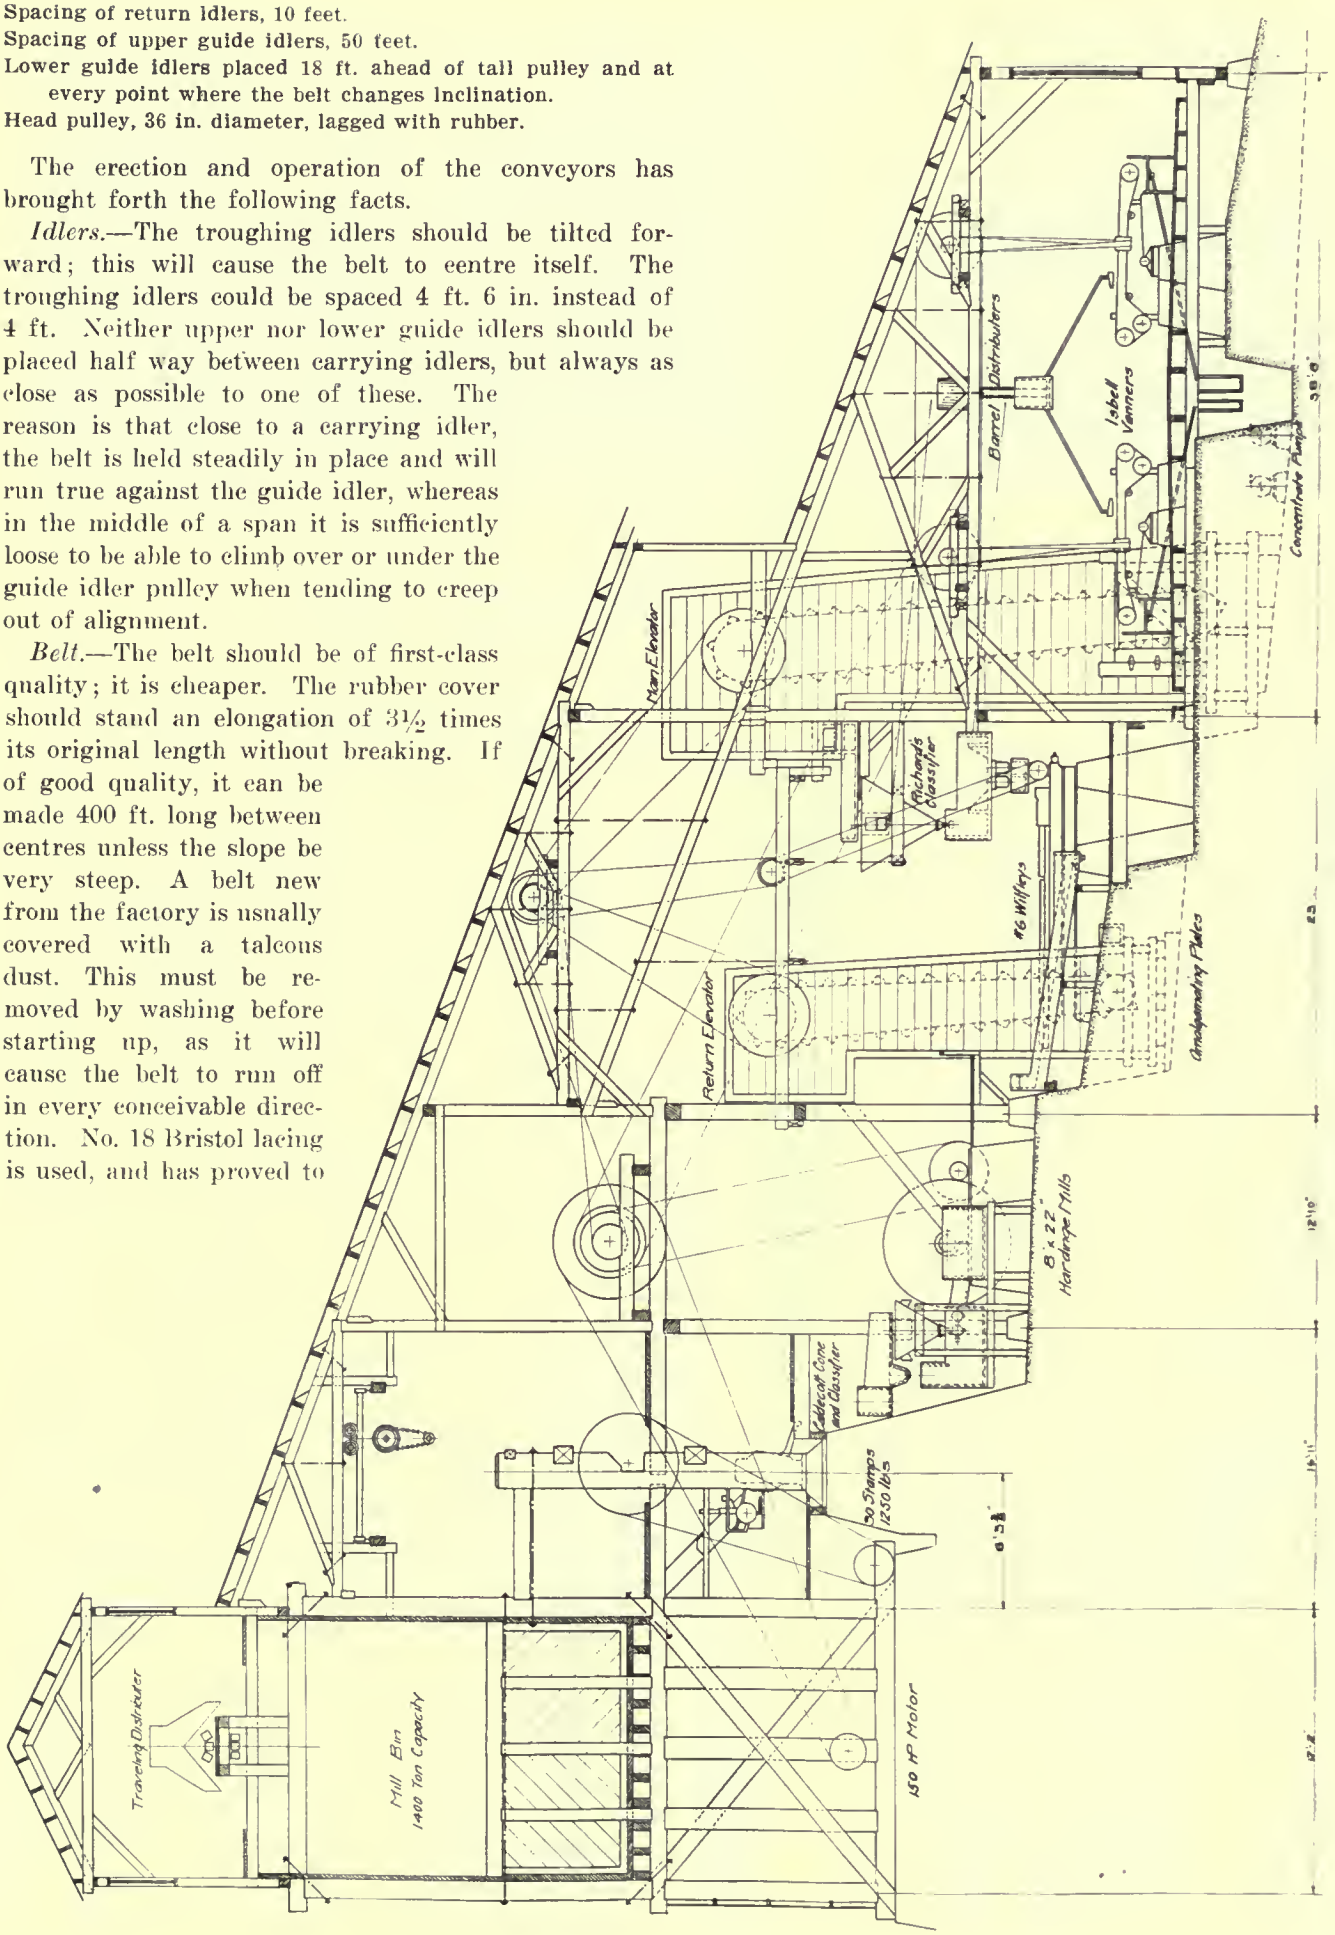

FIG. 2. CROSS-SECTION OF PLYMOUTH MILL.

be cheaper and more satisfactory than any other kind of lacing.

Slope.—On Mother Lode ore, which is damp and contains a large percentage of 'fines,' a 22°30′ slope is quite safe when the belt is loaded. On an empty belt, isolated and rounded pieces of ore will start rolling back if the slope is greater than 20°. At the Great Fitzroy mine, in Queensland, Australia, there is a conveyor in use having a slope of 28 degrees.

Take-up and tail pulleys.—Should have a heavy crown.

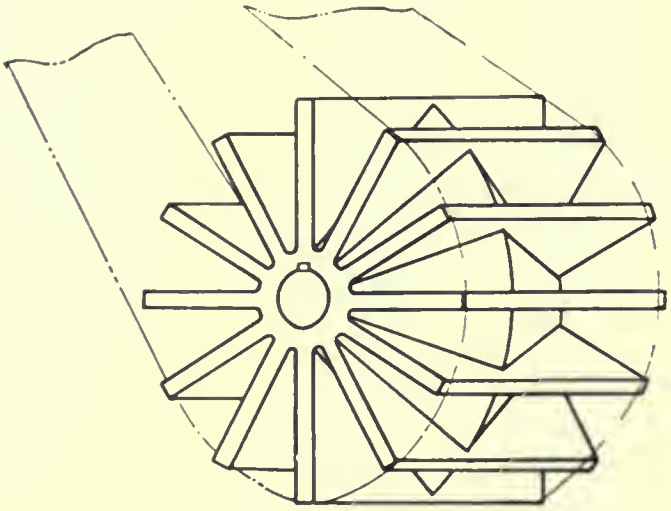

FIG. 3. BOSS ELEVATOR FOOT PULLEY.

The best type of pulley to use is the 'Boss' pulley (Fig. 3); the face consists of a series of rib-shaped spokes held by a very large double-conical hub. Coarse pieces of ore that fall on the undersize of the belt do not get pinched between the tail-pulley and the belt, but fall through the ribs on the conical hub and are thrown out sideways. A good tight floor under the upper belt will prevent rocks from falling on the lower belt. This is specially important near where the ore is fed on the belt.

Head pulley.—Long and steep belts should have head pulley of at least 42 in. diameter, lagged with rubber belting. This will prevent slipping and allow a looser belt.

Even in the best behaved mills, spouts will choke and the receiving box at the head of the conveyor will fill up in a few seconds. When this happens, the belt will scrape against the accumulated ore and is liable to be seriously damaged. It is necessary therefore to leave between the belt and the edge of the receiving box sufficient space to allow the ore to roll out on the floor.

Tripper.—Automatic trippers should not run at a speed greater than 10 ft. per minute, otherwise they will go to pieces when reversing. It is not only inconvenient but also dangerous to have a tripper start like a kangaroo when throwing-in the clutch.

ORE-BIN

The ore-bins are flat bottomed and have a capacity of 1400 tons, of which about 400 tons will run freely to the feeders. The balance forms a reserve in case of accidents to the crusher, conveyors, or to the mine. The maximum load on the posts supporting the bin is 304 lb. per square inch, but the timbers do not show any weight.

STAMPS

There are 30 stamps (D. D. Demarest), 1250-lb. weight, 104 drops, 7-in. drop, 5 stamps to the cam-shaft. Their capacity when crushing through 4-mesh screens (0.19-in. opening) varies from 11 to 14 tons per stamp, according to the character of the ore. The power required is 2.34 hp. per stamp, transmission and motor losses included.

The mortars are anchored by crossed bolts; this construction is good, but requires very close work in laying out the foundation pipes, and I believe the mortar foundation with a central tunnel is greatly preferable. Tests made to determine the right kind of mixture for the concrete proved that no standard rule can be followed, but that the ratio of cement, sand, and rock must be determined experimentally. The foundation of each ten stamps was poured in one continuous operation up to the top surface, the upper 2.5 in. consisting of a mixture of cement and fine sand in the ratio of 1 : 1½. The top was troweled to a smooth horizontal surface

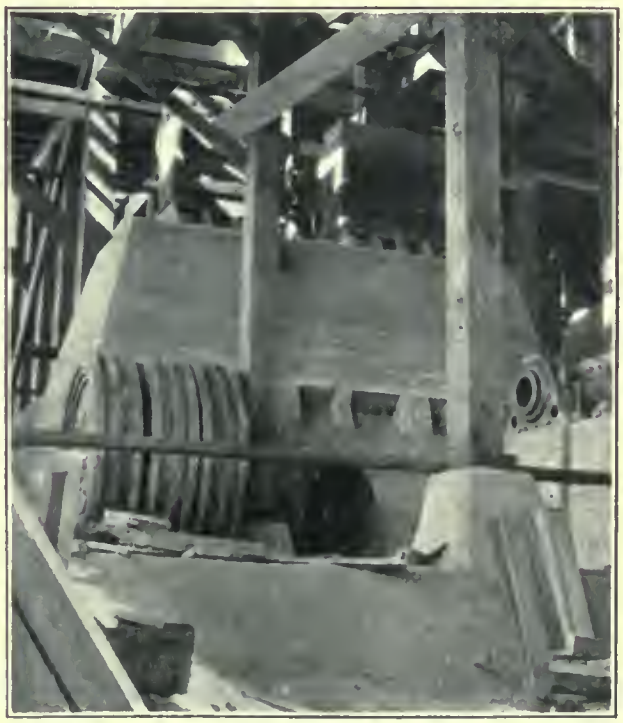

FIG. 4. CONCRETE FOUNDATION FOR STAMPS.

while setting. (See Fig. 4.) The batteries are very satisfactory and remarkably free of vibration.

Stamp v. Ball-mills.—There is no question that a stamp battery as a primary crusher is a most efficient and reliable machine; if, however, the remarkable friability of the Mother Lode ore be taken into consideration, the question comes up whether a ball-mill would not be a better suited machine for crushing the ore to 4-mesh size. If the size of the battery bins, the cost of the batteries, concrete mortar blocks, size of building required, and so forth, be taken into consideration, there

is no question that a ball-mill plant will cost not over one-third of a stamp-mill plant of equal capacity. The latest results of ball-mill operation indicate that with a proper feed load the steel consumption of a ball-mill can be kept within a half pound per ton of ore.

It is probable that a ball-mill will consume per ton of ore more steel than a coarse-mesh battery, but somewhat less power. If the line shaft, feeder, and battery repairs, screens, oil, and so forth, be also taken into consideration, it will be found that the total power and supply cost for crushing with ball-mills will be less than with stamps. There is no question that the cost of labor would be less, and so also the wear and tear on the building and the men. In the near future, reliable figures will become available on the comparative efficiency of these two types of machines, and I believe they will be in favor of the ball-mill.

Two-Stage Crushing

The advantages of two-stage crushing against stamping through a fine screen are both metallurgical and mechanical.

Metallurgical Advantages.—Sizing assay tests of the tailing of the Bunker Hill, the Amador, the South Eureka, the Argonaut, and the Plymouth plants show that the largest losses are in the coarse sizes and in the colloidal matter. The lowest grade portion of the tailing is the granular material passing a 100-mesh screen. The greatest amount of gold is in the colloids washed off by elutriation from the fine sand, and the gold content of the sand is directly proportional to the size of sand grains. When the ore is low-grade these differences are small, but on high-grade ore they become very marked. At the Plymouth a four-day composite sample of the total mill tailing gave the following screen analysis:

Mesh.	Per cent.	Value.	Per cent of total value.
On 40	2.36	$0.60	3.1
" 60	4.36	0.60	5.7
" 80	14.30	0.40	12.3
" 100	10.92	0.20	4.7
" 200	32.81	0.40	28.4
Through 200	35.25	0.60	45.8
Calculated total	100.00	$0.46	100.0

Note.—Of the minus 200-mesh material, about one-half is fine sand and one-half colloids.

From all this it appears evident that the ideal way to crush the Mother Lode ore is to crush it as fine as possible while producing the minimum amount of colloids. To crush very fine with the stamps requires a fine screen and a high discharge. This decreases the capacity of the stamps and increases the percentage of colloids. Therefore, the use of fine screens increases the slime losses, while the use of coarser screens increases the losses due to included sulphides in the coarse sand grains. The best results are obtained by two-stage crushing. At the Plymouth mill, the ore is crushed to 95% through 60-mesh and the percentage of true colloids is only 18%. This is due to the rapid discharge of the coarse battery screens and to the fact that the Hardinge mill will produce a smaller percentage of slime than any other grinding machine, the 'short tube-mill' excepted.

Mechanical Advantages.—The Plymouth mill is crushing 300 tons with 25 stamps and 2 Hardinge mills yielding a product less than 5% of which will not pass a 60-mesh screen. To approach similar results by direct stamping, it would be necessary to use approximately a 32-mesh screen, and the capacity per stamp would not be over 4 tons per day. Therefore, the two-stage crushing at Plymouth has the capacity of a 75-stamp standard Mother Lode mill. The crushing capacity of the stamps and Hardinge mills will increase proportionally to the coarseness of the product desired, and the above-given rating therefore holds true even when crushing through a 20-mesh screen.

A close estimate of the cost of grinding with the two Hardinge mills is as follows:

	Cost per day.
Danish pebbles, 400 lb. at $1.25	$5.00
Pebble lining (3 months), 6 tons	1.67
Placing lining	1.00
Power, 90 hp. at $4.50	13.50
Labor, 1.5 hr. at 35c	0.52
Oil and grease	0.04
Belts, 200 ft. in 12 months	1.07
Total cost per day	$22.80
Cost per ton milled	7.6c.

Local river pebbles, chiefly quartz, are now being used instead of Danish pebbles. They cost about $4 per ton, delivered at the mill, whereas the Danish pebbles cost approximately $27; but the consumption is about three times greater. The efficiency of the Hardinge mills does not seem to be much impaired by the softness and irregular shape of the local pebbles.

No accurate figures are yet available regarding the cost of operating the 25 stamps of the Plymouth plant, but it is reasonable to assume that the operating cost will remain the same whether crushing through 4 or through 32-mesh screen. If, therefore, the Plymouth plant be considered to correspond to an ordinary 75-stamp mill, it is evident that the Hardinge mills are doing the work of 50 ordinary stamps, crushing 4.0 tons per stamp, or a total of 200 tons per day, which corresponds to a cost of 11.4c. per ton for the share of work that the Hardinge mills are doing.

This proves that the cost of crushing with Hardinge mills compares favorably with that of stamping. The share of the work that the Hardinge mills do is done silently, without causing worries and troubles, without calling for violent physical exertion or skilled labor. It is on account of these considerations that I believe that a two-stage crushing plant consisting of ball and pebble-mills represents the simplest, cheapest, and most 'fool-proof' management for reducing a comparatively soft concentrating ore.

Whether a short tube-mill is more or less efficient

than a Hardinge mill is still a debated question. The tests being run at Miami and elsewhere will soon settle this question. I believe that if there is a difference it will be a small one; personally, I prefer a Hardinge mill, because I find that it gives a smaller percentage of oversize particles than a tube-mill.

Classifiers for the Hardinge Mills

The system of classifiers used is to place a small box acting as a Caldecott cone ahead of a sloughing-off cone, as shown in Fig. 5. This device works very satisfactorily. The Caldecott cone removes a large percentage of the coarse sand at about 30% moisture, thereby diminishing the amount of sand to be discharged by the sloughing-off cone and allowing the use of smaller spigots. It is easy to regulate the spigots of the two cones so as to have the desired dilution of the pulp fed to the Hardinge mills.

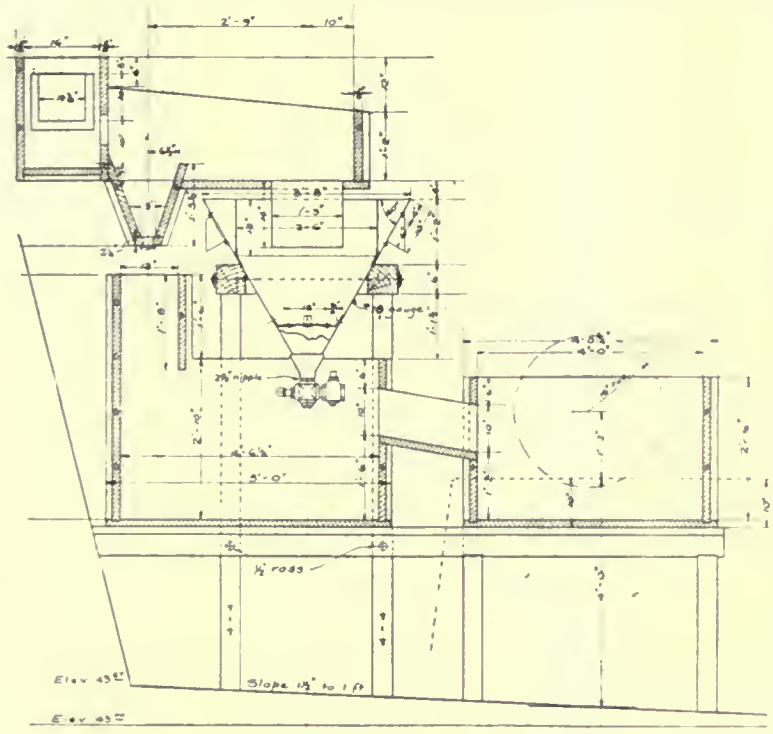

Fig. 5. Sand classifier for Hardinge mill.

Amalgamation

The problem of amalgamating is the only one that has not yet been worked out to complete satisfaction. The original plan was to amalgamate outside only, but after a few days it was found that part of the coarse gold would not catch on the plate. This coarse gold, if placed on quicksilver, will float without amalgamating, and to get it coated it is necessary to grind or rub it for some time in the presence of amalgam.

The next step was to feed quicksilver in the Hardinge mills and the amalgamation became complete. The plant was operated in this way for a month. It was found that if the amalgam was kept sufficiently soft it would build up on the pebble lining, filling up the depressions of the mortar between the pebbles. It was hopefully expected to find large amalgam balls rolling around with the pebbles, but this was not found to be the case; at the bottom of the mill there was a slough of amalgam, sand, and metallic iron which, in rolling, caused the coarse gold to amalgamate and, as the amalgam was formed, it became plastered upon the lining.

Whenever the feeding of quicksilver was stopped, the amalgam would dry up, crumble, and be thrown out of the discharge opening of the Hardinge, where it would build up in thick layers. This is a quick way for cleaning up the mills, though that of opening the mills and cleaning them up inside was not found any more laborious than that of cleaning up a battery of 30 stamps.

An unexpected result was that the amalgam, by remaining in the mill exposed to the continuous kneading action of the pebbles, became a very fine-grained pasty mass, all the coarse gold being ground or dissolved in the quicksilver. This amalgam therefore contained only 22% bullion, whereas it usually retorts close to 40% bullion. Inside amalgamation has now been discontinued, solely for the reason that the quicksilver losses were enormous, due to the flouring inside the mill. At present an amalgamating device is being attached to the mill, and this should effect the coating of the coarse gold, which will then catch on the plates.

From the results so far available, I judge that outside amalgamation will catch over 90% of the gold caught when using both inside and outside amalgamation. Each ounce of free gold that is caught in the concentrate instead of in the amalgam, represents a loss of $1.10 per ounce. The maximum recovery by amalgamation is approximately 65%, so that the net loss between inside and outside amalgamation on 300 tons of $5 ore is about $5.36.

Elevators

Two elevators are used, one for elevating the plate-tailing to the classifiers and one for returning the Wilfley tailing to the Hardinge mills. The general arrangement is shown in Fig. 6. Elevators are a bugbear to many millmen; if properly constructed, they do not give any trouble whatsoever. For the guidance of those who have not had experience with bucket-elevators, I will give a memorandum of the troubles and remedies.

1. *Elevator head pulley gets loose.*—Remedy, use heavy pulley with split hub and feather key resting in a short keyway. Use two set-screws on key and two set-screws on shaft. Use extra heavy shaft. For 16-in. belts over 30 ft. centre to centre, use not less than a $4\frac{7}{16}$-in. shaft. A bucket belt is a heavy affair, and will spring a light shaft; the revolving of the buckets will cause a rhythmical jarring of the pulleys, and these two actions combined will eventually loosen any pulley, however tightly fitted.

2. *Belt slips on head pulley.*—Remedy, lag the head pulley with 4-ply rubber belting. Use two belts touch-

ing each other along the crown-line, as thereby the crown of the pulley will remain true.

3. *Gear troubles and noise.*—Remedy, drive directly or by means of a counter-shaft. If an elevator sticks, something has to give way. If the elevator is geared, the bucket belt will give way, but if it is belt driven by a loose belt, it will throw the drive belt off and no damage is done.

4. *Spilling at receiver.*—Remedy, build the receiver so that the edge of the splitter is on a line drawn from the centre of the head pulley at an angle of 55° from the horizontal.

5. *Sand sticks in buckets.*—Remedy, drill three holes, $\frac{3}{16}$-in. diameter, through the bottom of the buckets; this will cause one bucket to leak into the following one, and prevents the sand from packing. When the bucket dumps, air is admitted through these holes to the back of the cake that has settled, and the pulp will dump freely.

6. *Splice breaking.*—Remedy, use Holtite or Jackson lacing. They will outlive any belt.

7. *Belt wears due to strain.*—Use light buckets, so as not to overload the belt. No. 10 gauge Salem buckets are strong enough for material finer than 5 mm. When elevating fine sand, it is immaterial whether the pulp be fed through the front or the back end of the elevator boot, because the fine sand is kept in suspension by the violent agitation caused by the splashing of buckets.

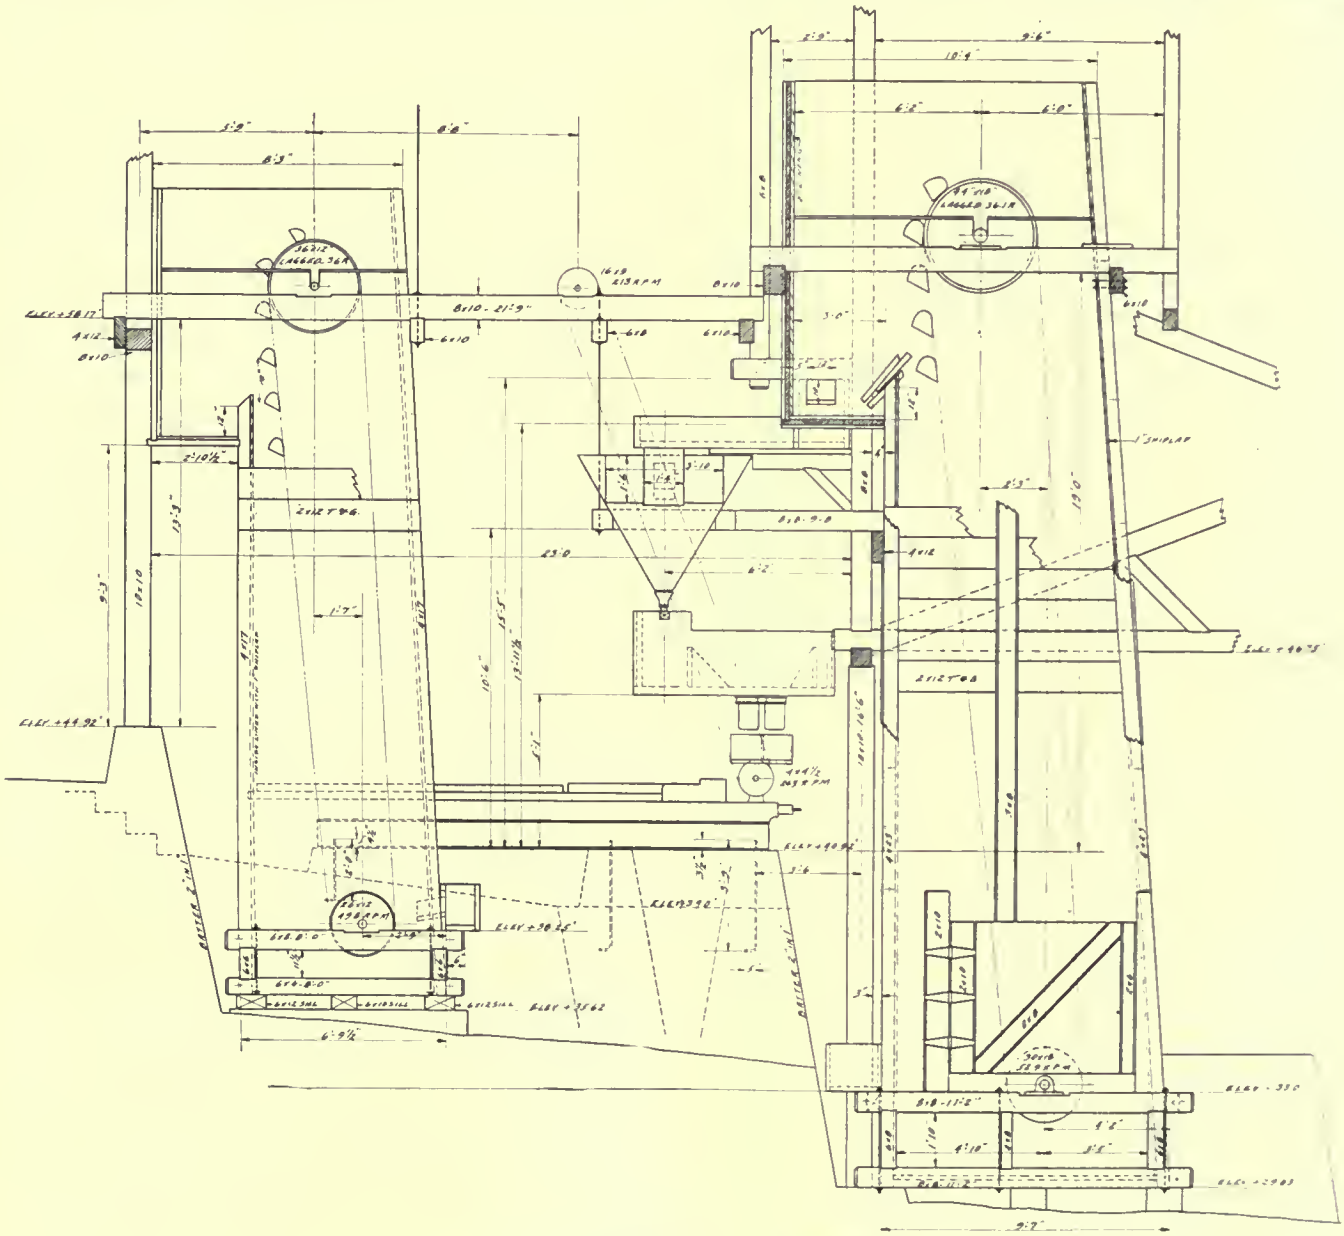

FIG. 6. ARRANGEMENT OF ELEVATORS.

Coarse material must always be fed directly into the bucket, care being taken to land it in the buckets as gently as possible.

Running off.—A heavy crown is necessary to keep the belt well centred. The use of the rubber washers mentioned later will assist the belt in feeling the crown of the pulley, whereas when the buckets are rigidly attached the belt becomes rigid and cannot hug the pulleys in a uniform way. The belt should always be at least one inch wider than the buckets. as this will pre-

vent the buckets from scraping against the elevator housing.

Wear under buckets.—Usually the buckets are either rigidly attached to the belt or a piece of rubber belting is inserted between belt and buckets. In both cases sand and small rocks will gradually get wedged between the buckets and the belt, and the repeated bending of the belt will gradually drive this sand in the rubber and wear it out. A radical remedy for this is the use of pure rubber washers, ¼-in. thick, of 1½-in. diameter, with a ¼-in. hole in the centre. These are inserted on each bolt between the belt and the bucket; when the bolts are tightened, the rubber washers are compressed and, owing to their softness, will keep in close contact with the belt even when bending over the pulleys, thereby preventing any sand from getting wedged between the buckets and the belt. These washers cause a clearance of $\frac{3}{16}$ in. between buckets and belt, and there is no chance for the sand to wedge anywhere. These washers will greatly lengthen the life of a belt.

Rocks wedging between pulley and belt.—'Boss' pulleys should always be used as boot pulleys when elevating material coarser than 3 mm. These have already been described when discussing the belt-conveyors. The use of 'Boss' pulleys will double the life of the belt.

Bearings for elevator boot shaft.—These should always be of the solid closed pattern shown in Fig. 7. Every time an elevator stops, the pulp will overflow over the bottom bearings, which are exposed to this and other hardships. In many mills, they are buried out of sight, the shaft usually revolving in grit instead of babbitt.

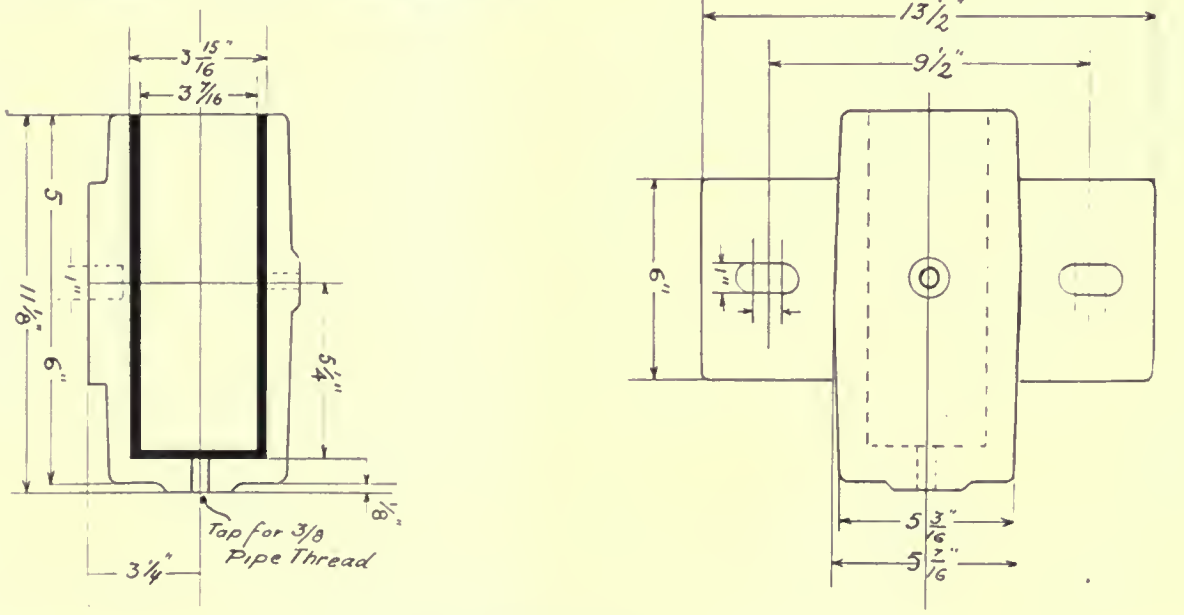

FIG. 7. SOLID BEARING FOR BUCKET ELEVATOR.

Elevator buckets.—Large buckets should always have two rows of bolts, for the reason that when the bucket line arrives at or leaves the pulley the buckets are violently jerked forward or backward, and the bolts, if in a single row, will snap off within a short time. On large buckets not less than seven $\frac{5}{8}$-in. bolts should be used.

CONCENTRATING TABLES

Two No. 6 Wilfley tables and 30 Isbell vanners are used for concentration. My long personal experience with vanners had convinced me that of all tables the vanner is the most costly and troublesome one to operate, and at one time I was convinced that never again would I place vanners in a new plant. Upon closely investigating the Mother Lode ore, I came to the conclusion that vanners were the most suitable machine, and I will explain why.

The characteristics of the Mother Lode ore are: (1) the waste contained in the ore is chiefly slate, which will break up into flakes that are easily washed off into the tailing; (2) the quartz is very light; (3) there is a large percentage of colloidal slime in the ore, and this, by increasing the viscosity of the pulp, tends to keep the sand in suspension—therefore the pulps will flow freely on the plates and tables and in the launders at much less grade than is usual in other districts; (4) the pyrite occurs in well formed crystals and in bunches—it is therefore easily freed by crushing, and the percentage of middling having a specific gravity intermediate between that of the pyrite and of the quartz is comparatively small; (5) the middling of a Wilfley

table consists chiefly of small particles of free pyrite washed over into the tailing; (6) the Plymouth ore contains a large percentage of arsenopyrite occurring in small crystallized grains; owing to its high specific gravity it will separate above the pyrite, giving the appearance of being a streak of galena.

The vanners are well suited to handle this kind of ore. The gangue is very light, and when kept in agitation it will flow so easily off the vanner belt that the sulphides can be drawn up through the wash water without being much disturbed. Comparatively large grains of gangue, that usually would be dragged over into the vanner concentrate, are instead, on account of their lightness, washed off into the tailing. This explains why Frue vanners are capable of handling efficiently such large tonnages of Mother Lode ore; in most mills of the district the 6-ft. vanners have a load of 11 tons, though better work is obtained by reducing the load to 8 tons. At Plymouth, the average load per vanner is about 8.3 tons. Panning of the vanner tailing proves that a very small percentage of the free sulphides is lost, and therefore no other machine could do much better work than the vanner. This is explained by the very small percentage of middling contained in the pulp.

Ratio of Concentration

The ratio of concentration of the Plymouth ore (when producing concentrates of shipping grade) is approximately 100 into 1.8. With this very high ratio of concentration, a Wilfley or a Deister table would have thrown out a very thin streak of concentrate which would be hard to separate accurately. To use these tables, it would be necessary to separate also a streak of middling that would have to be returned to the classifier. A vanner instead is able to separate any small percentages of sulphide as free of silica as desired. Even on vanners a certain amount of gangue has to be drawn over with the concentrate so as to reduce the tailing loss, but this percentage is more easily regulated and is less than would be the case when using Wilfley or Deister tables.

Freight and haulage charges on concentrate are heavy, especially at Plymouth; the smelters place a heavy penalty on silica, and their schedule on gold payments calls for high-grade products. It is therefore essential to produce a clean concentrate, and to obtain this a vanner is better suited than any other table unless both middling and concentrate of these tables be re-treated on secondary machines.

Tests are being run now to determine the relative economical efficiency of vanners when making high-grade and low-grade concentrates; accurate results are not yet available, but the indications are that the difference will be small. I expect it to be of the same order as the recovery obtained in other mills of the district by the use of canvas plants. The increase in economic recovery, however, may even be negative, as the increased gold saving may be more than offset by the increased haulage, freight, and treatment charges.

Cyaniding of Concentrates

Laboratory tests give very encouraging results. A weak cyanide solution will in a short period of time extract over 91% of the gold, the cyanide consumption being low. The tests do not show any fouling of the solutions, notwithstanding the large arsenic content of the concentrate; this will have to be verified by running long-time tests.

There appears to be a considerable margin of profit in cyaniding the concentrate; when doing this, it will be profitable to lower the grade of the concentrate to about $20 per ton, as the metallurgical recovery will then be higher, not only on account of the larger percentage of sulphides saved, but also on account of the gold contained in the sand dragged over into the concentrate. Recapitulating, I will say that, whereas in concentrating for smelter shipments it does not pay to attempt to increase the gold recovery by lowering the grade of the concentrate, the contrary is true when producing a concentrate that is to be cyanided. The sand dragged over into the concentrate is mostly clean quartz, free of that carbonaceous matter that causes the reprecipitation of the gold usually noticed when attempting to cyanide the Mother Lode tailings. The presence of some sand in the concentrate will assist grinding, settling, and, in a general way, the handling of the pulp.

Returning now to the subject of tables *versus* vanners, I will say that if the concentrate is to be cyanided it will be best to use Wilfley and Deister tables, the reason being that these machines are much cheaper to operate than vanners.

The question of whether to melt or cyanide the concentrate has not yet been decided at the Plymouth plant, and for this reason preference was given to the vanners. The Isbell vanners were chosen in place of Frue vanners for the reason that most reliable information received from various quarters indicated that the Isbell vanner is more easily and more cheaply operated than the Frue, and the first two months of operation at Plymouth amply confirm this.

Classification

The classification system of the Plymouth plant consists of a sloughing-off cone followed by a two-spigot Richard hindered-settling classifier, as shown in Fig. 6. The sloughing-off cone has an inside cylinder, which causes it to work like a spitzlutte. The area of the classifying column is so calculated that the flow of the pulp will carry over only material finer than 40-mesh. All the coarser material discharges through the bottom spigot together with a certain amount of slime, and this discharge, suitably diluted, flows to the two-pocket Richards hindered-settling classifier, where the coarse sand is separated from the fine sand and slime. The classifier discharges are fed to two No. 6 Wilfley tables and the fine-sand overflow of the classifier goes to six Isbell vanners which are especially adjusted for handling this comparatively coarse material. This two-

step classification gives very satisfactory results, as the bulk of pulp to be separated by hydraulic classification is greatly reduced. The overflow of both the cones and the classifier is sent to distributing barrels (see Fig. 8), and is distributed automatically by these to the vanners.

The Mother Lode ore is so easily concentrated that

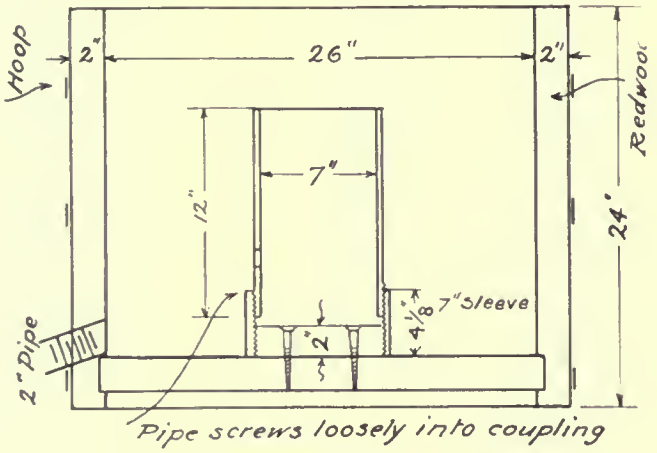

FIG. 8. DISTRIBUTING BARREL FOR VANNERS.

it does not require close classification. Tests made in various plants of the district have proved that there is no decided advantage in hydraulic classification, which usually dilutes the pulp to such an extent that it does more harm than good.

The object of the classification at Plymouth is twofold: The first object is to separate all the coarse material which requires further grinding; the second object is to remove the coarse sand from the vanners, which thereby are relieved of a large portion of the material most difficult for them to handle; the classifiers also protect the vanners from oversize material that occasionally gets into circulation owing to accidents of some kind or other.

Most of the hydraulic water used in the classifier goes to the Wilfley table, and here it is separated and sent to waste, so that the Plymouth system of classification does not cause any appreciable dilution of the pulp.

Sectional samples taken along the discharge edge of the Wilfley tables show that the highest losses are contained in that portion of the tailing which is nearest to the concentrate, and in the very coarse grains which are discharged close to the head-motion end of the table. When the ore is low-grade, only the first half of the Wilfley tailing is returned to the Hardinge mills; but when the ore is high-grade, that is, when it will assay over $6 per ton, then the total Wilfley tailing is returned for regrinding.

The six Isbell vanners working on the overflow of the hydraulic classifier handle a pulp consisting chiefly of 60 to 100-mesh sand almost free of colloidal matter, and on these vanners the tailing losses due to slimed sulphides are therefore comparatively small.

The largest percentage of the total tailing loss is due to the gold contained in the colloids. What the cause of this loss is, has not yet been thoroughly investigated, but probably it must be debited to the arsenopyrite, which has a tendency to float. With the two-stage crushing system in use at the Plymouth plant, this loss has probably been reduced to less than that in most plants of the district.

METALLURGICAL AND ECONOMIC RECOVERIES

The metallurgical and economic recovery of the new plant has not yet been determined accurately, for the reason that the automatic samplers have been installed only lately, and also because no accurate tonnage figures will be available until the automatic weigher is installed on the belt-conveyor. Judging from the comparative assay of the ore, concentrates, and tailing, it appears that the recovery must be very close to 90%. The average assay of all samples so far taken since the starting up of the plant:

	Number of samples.	Avg. gold assay, oz.
Heads	45	0.2430
Plate tailing	25	0.1070
Total tailing	49	0.0288
Wilfley tailing	9	0.0395
Vanner concentrate	45	3.0600
Wilfley concentrate	45	6.7500

Explosives Manufactured in the United States in 1913

The production of explosives in the year 1913 has just been published by the U. S. Bureau of Mines. The total output, according to the figures received from manufacturers, was 463,514,881 lb. (231,757 short tons), as compared with 489,393,131 lb. (244,696) short tons, in 1912. This production is segregated as follows: black powder, 194,146,747 lb.; 'high' explosives, other than permissible explosives, 241,682,364 lb.; and permissible explosives, 27,685,770 lb. These figures represent a decrease of 36,146,622 lb. of black powder, and an increase of 7,212,872 lb. of high explosives, and 3,055,500 lb. of permissible explosives. The figures show that in 1902 only 11,300 lb. of permissible explosives was used in coal mining, whereas in 1913 the quantity so used was 21,804,285 lb. The quantity of permissible explosives used in the United States is larger than in a number of foreign countries. In 1912 it represented about 5% of the total quantity of explosives produced, and in 1913 6%. The total amount of explosives used for the production of coal in 1913 was 209,352,938 lb., of which about 10% was of the permissible class, compared with 8% in 1912. The use of permissible explosives in coal mining has had gratifying results, and few, if any, serious accidents can be attributed directly to their use.

THE New Zealand Sulphur Co. has spent about $100,000 in preparations for mining sulphur on White island, a volcanic area in the Bay of Plenty of the North Island, but during September it was found that the camp had been demolished and 10 men killed by the collapse of a high cliff; probably by some volcanic disturbance

Secondary Sulphide Enrichment of Copper Ores With Special Reference to Microscopic Study

By AUSTIN F. ROGERS

It is now a well established fact that many workable copper deposits, especially of the disseminated type, owe their value to the process known as secondary sulphide enrichment. Considerable interest attaches to secondary enrichment from both a scientific and economic standpoint. The theory of secondary sulphide enrichment was first clearly announced in 1900 by W. H. Weed,[1] by S. F. Emmons,[2] and by C. R. Van Hise,[3] independently, though both James Douglas[4] and J. F. Kemp[5] had recognized a zone of enrichment at Butte, Montana. F. De Launay,[6] the leading French authority on ore-deposits, had imperfectly outlined the process of sulphide enrichment in 1897, but it was first hinted at by Gonzalo y Tarin[7] in his monograph on Huelva (Spain) in 1888. In Huelva are situated the famous pyritic deposits of Rio Tinto, in which not only Gonzalo y Tarin, but also F. Klockmann[8] and J. H. L. Vogt[9] found evidences of enrichment. In spite of the preliminary work of these European geologists, the principle of secondary sulphide enrichment was first clearly established by American geologists and Americans have also made the principal contributions to the subject since that time. Though the German writers on ore deposits recognize secondary enrichment under the name *die zone der reichen sulphide* or *zementationszone,* they lay little stress upon it.

Geological Study of Secondary Enrichment

The study of secondary sulphide enrichment may be approached from the geological, chemical, or microscopic standpoints. A fairly detailed geological study of secondary enrichment has been made at a number of American mining districts. An excellent summary of sulphide enrichment has recently been given by W. H. Emmons.[10] and the influence of topography, altitude, climate, glaciation, structure, etc., upon secondary enrichment is known in a general way at least.

Chemical Study of Secondary Enrichment

While much remains to be done upon the experimental side, our knowledge of the chemical processes involved in sulphide enrichment is fairly complete in its broad outlines. The first experimental work in sulphide enrichment was probably done by C. F. Tolman, who, working under the direction of H. V. Winchell[11] in 1899-1900, produced cuprous sulphide films on pyrite. This experiment was an attempt to explain the occurrence of the Butte chalcocite.

In attempting to explain covellite pseudomorphs after sphalerite found at Galena, Kansas,[12] in 1900 I produced cupric sulphide by heating zinc sulphide and copper sulphate together in a sealed tube. Covellite as a replacement of sphalerite has since been observed by Lindgren, Irving, Butler, and others. The experimental work of H. N. Stokes,[13] R. C. Wells,[14] and E. C. Sullivan[15] has furnished valuable clues to the possible chemical changes involved in secondary enrichment. The best discussion of the chemistry of sulphide enrichment in electrolytic solutions is that by A. C. Spencer,[16] while the recent work of J. D. Clark[17] at Stanford University throws much light upon the rôle of colloidal solutions in sulphide enrichment.

Microscopic Study of Secondary Enrichment

Advances in the study of secondary enrichment in the near future are likely to be largely on the microscopic side. It is with this phase of the subject that the present paper is concerned. Discussion is limited to copper minerals and applies especially to chalcocite enrichment.

The use of the metallographic or reflecting microscope in the study of opaque ores and minerals was first pointed out by Wm. Campbell.[18] Since the application of the metallographic microscope to the study of the Cobalt (Ontario) ores,[19] brief scattering papers have appeared from time to time, but the recent paper of L. C. Graton and J. Murdoch,[20] on 'The Sulphide Ores of Copper—Some Results of Microscopic Study,' constitutes an important contribution of some length. With this paper the microscopic study of secondary sulphide enrichment may be said to have fairly begun. In a recent microscopic study of a magmatic copper sulphide ore from the Engels mine in Plumas county, Cali-

fornia. I[21] came to the conclusion that the chalcocite and the covellite had been formed at the expense of the bornite by ascending solutions. To express this idea the term 'upward secondary sulphide enrichment' was coined. But before upward enrichment is discussed it is necessary to review our conception of downward enrichment.

Downward Sulphide Enrichment

The theory of downward sulphide enrichment may be briefly summarized in the words of W. H. Emmons.[22] "Many deposits, especially of ores of copper, are leached near the surface and are richer below the leached zones. The ore at still greater depths is of lower grade. According to the theory the copper leached from the upper zone has been carried downward and re-deposited, forming an enriched zone, and the deeper, lower grade sulphide ores are assumed to be like the original or primary mineralization of the whole deposit." The review of secondary enrichment by W. H. Emmons, from which the above paragraph is taken, is the most complete one that has yet appeared. C. F. Tolman[23] also has published an excellent short summary. But practically all that has been written on sulphide enrichment applies only to downward enrichment. The possibility of enrichment by ascending solutions is ignored and it is assumed that sulphide enrichment is always produced by descending solutions. It is significant, however, that the title of an important paper by F. L. Ransome,[24] is 'Criteria of Downward Sulphide Enrichment.'

Upward Sulphide Enrichment

A brief microscopic examination of some of the rich chalcocite-bearing ores from Butte furnished me evidence that the massive chalcocite had been formed at the expense of bornite. Taking this together with geological evidence given by Reno Sales,[25] that chalcocite was formed by ascending solutions, there was practically proof of the formation of the Butte chalcocite by upward secondary sulphide enrichment. This was announced in a paper[26] published in December 1913. The microscopic work of the writer has been checked by the detailed work of J. C. Ray,[27] who proves that the chalcocite is a metasomatic replacement of other minerals, including bornite as well as enargite and covellite. The geological evidence brought forward by Mr. Sales is incontrovertible, and the same may be said of the microscopic work of Mr. Ray.

As was the case in downward enrichment, it also is found that there are hints of the idea of upward enrichment in the literature. Mr. Weed,[28] for example, attributes the bonanza silver ores of Neihart, Montana, and the enargite of Butte, Montana, to secondary enrichment by ascending solutions. Mr. Kemp,[29] in discussing deep-seated chalcocite at Butte, says: "Most reasonable of all would appear to be W. H. Weed's suggestion of secondary enrichment by uprising solutions of copper set in action perhaps by the late rhyolite. * * * Mr. Weed applies his conclusions to the enargite at Butte, but as the glance is being found deeper and deeper we may at least raise the question whether the lower deposits may not also have been introduced from the depths."

In the Engels mine, Plumas county, California, recently described by H. W. Turner and A. F. Rogers,[30] there is evidence of the formation of chalcocite and covellite by ascending hydrothermal solutions which replaced bornite. The bornite in this case is of magmatic origin and there is no evidence of two generations of bornite. The occurrence of chalcocite in hard, dense norite-diorite and in tight pegmatites, both of which are slightly sericitized, but with no evidence of silicification, kaolinization, or oxidation, is an argument in favor of enrichment by ascending solutions. In the Engels mine there seems to have been continuity in ore-deposition beginning with the early magmatic stage (magnetite), progressing through the late magmatic stage (chalcopyrite and bornite) and ending with the hydrothermal stage (chalcocite). The apparent relation of the chalcocite-bearing ores to present surface topography may be explained by the experimental work of J. D. Clark,[31] who found that colloidal copper sulphides may be precipitated by the loss of a dispersing agent (hydrogen sulphide) without the intervention of electrolytic solutions. Tolman and Clark[32] have recently advanced the thesis "that the zones of ore deposition correspond to the zones of escape of volatile dispersing agents." There is no evidence of a definite zone of secondary enrichment in the Engels mine, and the absence of pyrite probably accounts for the absence of downward enrichment, for as far as known, downward sulphide enrichment is dependent upon pyrite, marcasite, or pyrrhotite.

With definite proof, at least for the Butte ores, of the formation of chalcocite at the expense of bornite by ascending solutions, checked as it is by the work of J. D. Clark, there can be but little doubt as to the fact, but there is room for differences of opinion as to the terms to be used. Some will object to the term 'upward secondary enrichment' and will use the term 'primary enrichment' for the process outlined in the preceding paragraphs, but as Mr. Ransome[33] has pointed out: "The term *primary* * * * denotes merely a sequential relation * * *" Much confusion has resulted from the use of terms 'primary' and 'secondary' in the double sense of sequence and genesis. Graton and Murdoch[34] use the

[34] *Loc. cit.*

term 'primary' for minerals produced by hot ascending solutions and 'secondary' for minerals produced by cold descending solutions and have apparently overlooked the fact that some of the copper sulphides have resulted from the replacement of earlier formed sulphides by means of ascending solutions. Yet in this same paper they often use these terms in a mineralogical sense.

In my opinion, it is preferable to use the terms 'primary' and 'secondary' in the mineralogical sense. By a secondary mineral the mineralogist means one that is formed at the expense of, or by the replacement of an earlier formed mineral. 'Upward' and 'downward' (or Mr. Ransome's equivalent terms, 'hypogene' and 'supergene'[35]) may then be used to indicate the source of the solutions. The logical term for the process by which the Butte chalcocite was produced is 'upward secondary sulphide enrichment,' for enrichment involves any natural process of increasing the value of an ore, sulphides or sulpho-salts are involved, the chalcocite is secondary in a mineralogical sense, and the solutions were ascending. The only objection is that 'enrichment' is a geological, rather than a mineralogical term, in that the orebody or zone as a whole, not a polished section or single hand specimen, is considered. In view of this, it is doubtful whether the term 'secondary enrichment' itself may be consistently used. C. F. Tolman, writing in the *Mining and Scientific Press,* January 24, 1914 (Vol. 108, p. 172), has remarked: "It would be difficult to invent a more inappropriate and inaccurate name for the process than 'secondary sulphide enrichment'."

Another point to be considered is that chalcopyrite and bornite are often formed by the replacement of pyrite, usually by ascending solutions, and, as pointed out by Tolman and Clark, many so-called primary (hypogene) ores are the product of successive stages of mineralization by replacement. In a mineralogical sense these are also secondary. There should be some agreement as to the use of these terms. I do not insist upon the term 'upward enrichment,' but simply use it for the sake of argument until the whole matter is threshed out.

Microscopic Characters of the Copper Sulphide Ores

The microscopic study of polished sections of the copper sulphide ores reveals many interesting relations. Minerals that are apparently pure and homogeneous often prove to be mixtures. Metasomatic alteration of one mineral by another is common, and the various changes brought about by ore-forming solutions seem to have been faithfully recorded. Some of the transformations are so sluggish that remnants of the early stages are often preserved through the later stages.

On the accompanying plates, I and II, I have assembled a picked lot of microphotographs of polished sections of enriched copper sulphides from nine different localities. These photographs were taken with the large Leitz microscope. Colored screens were used to bring out contrasts in the minerals. The irregular dark areas are cavities gouged out during the grinding of the section, and the fine sharp lines are scratches produced during the final polishing.

Discussion of copper sulphide deposits usually involves a discussion of pyrite, chalcopyrite, bornite, chalcocite, and covellite. Of these sulphides, pyrite is the earliest formed mineral and is often present as residual grains (Fig. 4 and Fig. 6), persistent in the very late stages. Pyrite is nearly always an original mineral. Chalcopyrite and bornite are often formed at the expense of pyrite, usually by ascending solutions. For the most part they are practically contemporaneous (Fig. 1), though bornite is a little later, that is, the periods of formation overlap. Either chalcopyrite or bornite (not often both, as Spencer has emphasized) is usually an intermediate step in the transformation of pyrite to chalcocite.

Chalcocite is practically always a metasomatic mineral except locally. Chalcocite crystals have been found in cavities in the Edith May vein of the Speculator mine (2400-ft. level) at Butte, by J. C. Ray, and minute chalcocite crystals in cavities were found by C. F. Tolman at the Gray mine, Globe, Arizona. Distinct chalcocite crystals are also known from Cornwall, from Montecatini, Italy, from Bristol, Connecticut, and from several other localities. Chalcocite is formed at the expense of both chalcopyrite (figures 1 and 3) and bornite (figures 1, 2, 4, and 6 to 12), but seems not to form from pyrite while either chalcopyrite or bornite is present. Fig. 4 furnishes evidence of this fact. The bornite is a replacement of pyrite and the chalcocite of bornite, but the cessation of pyrite replacement during the chalcocite stage is evident. Veinlets of chalcocite in pyrite from the Ludwig mine, Lyon county, Nevada, and from Bingham, Utah, contain residual specks of chalcopyrite, showing clearly that the chalcocite is a replacement of chalcopyrite, but not of pyrite. Mr. Lindgren[36] states that "pyrite apparently does not precipitate Cu_2S or CuS while zinc-blende is present." Mr. Spencer[37] comments on the scanty replacement of pyrite by chalcocite in the porphyry ores of Ely. In view of these facts, the statement[38] that chalcocite is the usual derivative of pyrite is questioned. The presence of residual grains of pyrite in a matrix of chalcocite is no proof that the chalcocite replaced pyrite. Figures 5 and 6 of Graton and Murdoch's paper[39] prove that the chalcocite is a metasomatic alteration of bornite, but not of pyrite. But undoubtedly under certain conditions pyrite changes directly to chalcocite. The chalcocitization of pyrite has been proved by Mr. Lindgren at Morenci, Arizona, and by Mr. Tolman at Ray, Arizona. The condition favoring chalcocitization of pyrite is probably either acidity of the solutions (indicated by the Winchell-Tolman synthesis of chalcocite) or long-continued action of the solutions.

Covellite is formed at the expense of both chalcopyrite (Fig. 5) and bornite (Fig. 9), usually in lath-shaped

or acicular crystals. It is formed both by ascending (Fig. 5) and by descending (Fig. 9) solutions and often accompanies chalcocite.

Chalcopyrite of the second generation is fairly common in small amounts, as has been pointed out by Graton and Murdoch. It usually occurs as narrow gashes in bornite and can easily be distinguished from chalcopyrite of the first generation by structural relations. As it is produced by both upward and downward enrichment, it is probably formed under alkaline conditions. The neutralization, at depth, of the acid solutions which produce downward sulphide enrichment was first emphasized by Mr. Tolman.[40]

The general order of succession of the usual minerals involved in secondary enrichment is: (1) pyrite; (2) chalcopyrite; (3) bornite; (4) covellite; (5) chalcocite. Chalcocite may be followed by melaconite (Fig. 6) or cuprite, and these in turn by malachite, azurite, or chrysocolla. The only important reversal of this order is the formation of a second generation of chalcopyrite after the bornite. The formation of chalcocite does not necessarily involve the intermediate steps of chalcopyrite, bornite, and covellite, for it may form directly from bornite (figures 1, 2, 4, and 6 to 12) from chalcopyrite (Fig. 3), and even from pyrite. The tarnishes observed on chalcopyrite by Mr. Spencer[41] are simply interference colors due to thin films and there is no proof that these films are covellite and chalcocite.

This paper is an attempt at the standardization of the two contrasted types of secondary sulphide enrichment, one brought about by descending solutions, the other by ascending solutions. Graton and Murdoch attempted to distinguish primary (hypogene) structures and secondary (supergene) structures, but they do not clearly differentiate the two types. They have paved the way for future work, and without their valuable paper the present paper would not have been possible. These types are based upon the study of a number of specimens of known geologic occurrence. It may seem premature to attempt this standardization from a study of a limited number of specimens, but if the microscopic work is to be of much value, generalizations of this nature are necessary.

Microscopic Criteria of Downward Sulphide Enrichment

Figures 1 to 6 are believed to represent types of alteration brought about by descending solutions. The solutions have penetrated the earlier sulphides along anastomosing channels and have produced a structure which is regular compared with that due to ascending solutions (compare figures 7 to 11).

Narrow veinlets of quartz related to the introduction of chalcocite (figures 1 and 6) or covellite (Fig. 5) are characteristic of downward enrichment. The occurrence of melaconite as an alteration of chalcocite (Fig. 6) is also characteristic of this type. Remnants of bornite (figures 4 and 6) and chalcopyrite (Fig. 5) resulting from replacement by chalcocite are sub-angular.

Figures 1 and 2 are microphotographs of specimens from the mineralized quartz-monzonite of Bingham, Utah, extensively mined by the Utah Copper Co. These are both from narrow solid veins of sulphides cutting the monzonite. In Fig. 1 chalcopyrite and bornite are both altered to chalcocite along narrow veinlets. Some of the Bingham polished sections also show melaconite as an alteration product of chalcocite. According to J. M. Boutwell[42] the disseminated chalcocite of the quartz-monzonite is the result of downward enrichment. A specimen of massive chalcocite with a few remnants of bornite (Fig. 2) on being etched with nitric acid develops structure which proves that the individual chalcocite crystals must be at least 1 cm. in size. This shows that Graton and Murdoch's[43] criterion of supergene chalcocite based upon the well developed cleavage cannot be relied upon.

Fig. 3 represents the change of chalcopyrite to chalcocite in a specimen from the sulphide enrichment zone at the Ludwig mine, Lyon county, Nevada. There is a rather indefinite zone of rich chalcocite-bearing ore just below the oxidized zone and above the low-grade chalcopyrite-bearing pyrite. The presence of selenite in the chalcocite-bearing ore is proof of downward enrichment. Fig. 4 is a microphotograph of a specimen from 3S level of the Poderosa mine at Collahuasi, Chile, collected by B. Bryan and C. L. Severy. Not very much is known about the geology of the Poderosa mine, but the chalcocite is undoubtedly formed by descending solutions. In Fig. 5 (Rambler mine, Wyoming) is represented the replacement of chalcopyrite by acicular crystals of covellite along definite crystallographic directions. The ingress of the covellite-forming solutions along narrow quartz veinlets is indicative of supergene origin. Fig. 6 is a microphotograph of a lignite replacement from the Sierra Oscura mountains, New Mexico, collected by H. W. Turner. The so-called chalcocitized lignite of this ore deposit consists of hematite, pyrite, bornite, chalcocite, and melaconite, formed in succession in the order named. Narrow rims of chalcocite are formed around, and at the expense of the bornite. The occurrence of melaconite surrounding the chalcocite is considered proof of the action of descending solutions at a late stage at least. From the geological evidence brought forward by Mr. Lindgren[44] in a discussion of the 'Red Beds' type of ore deposit, to which the Sierra Oscura deposit belongs, it is probable that all the minerals mentioned were deposited by descending solutions. This question will be discussed in a forthcoming paper.

Microscopic Criteria of Upward Sulphide Enrichment

Butte is taken as the type of upward enrichment deposit, for the geological work of Sales combined with the

PLATE II. MICROPHOTOGRAPHS OF POLISHED SECTIONS ILLUSTRATING UPWARD SULPHIDE ENRICHMENT.

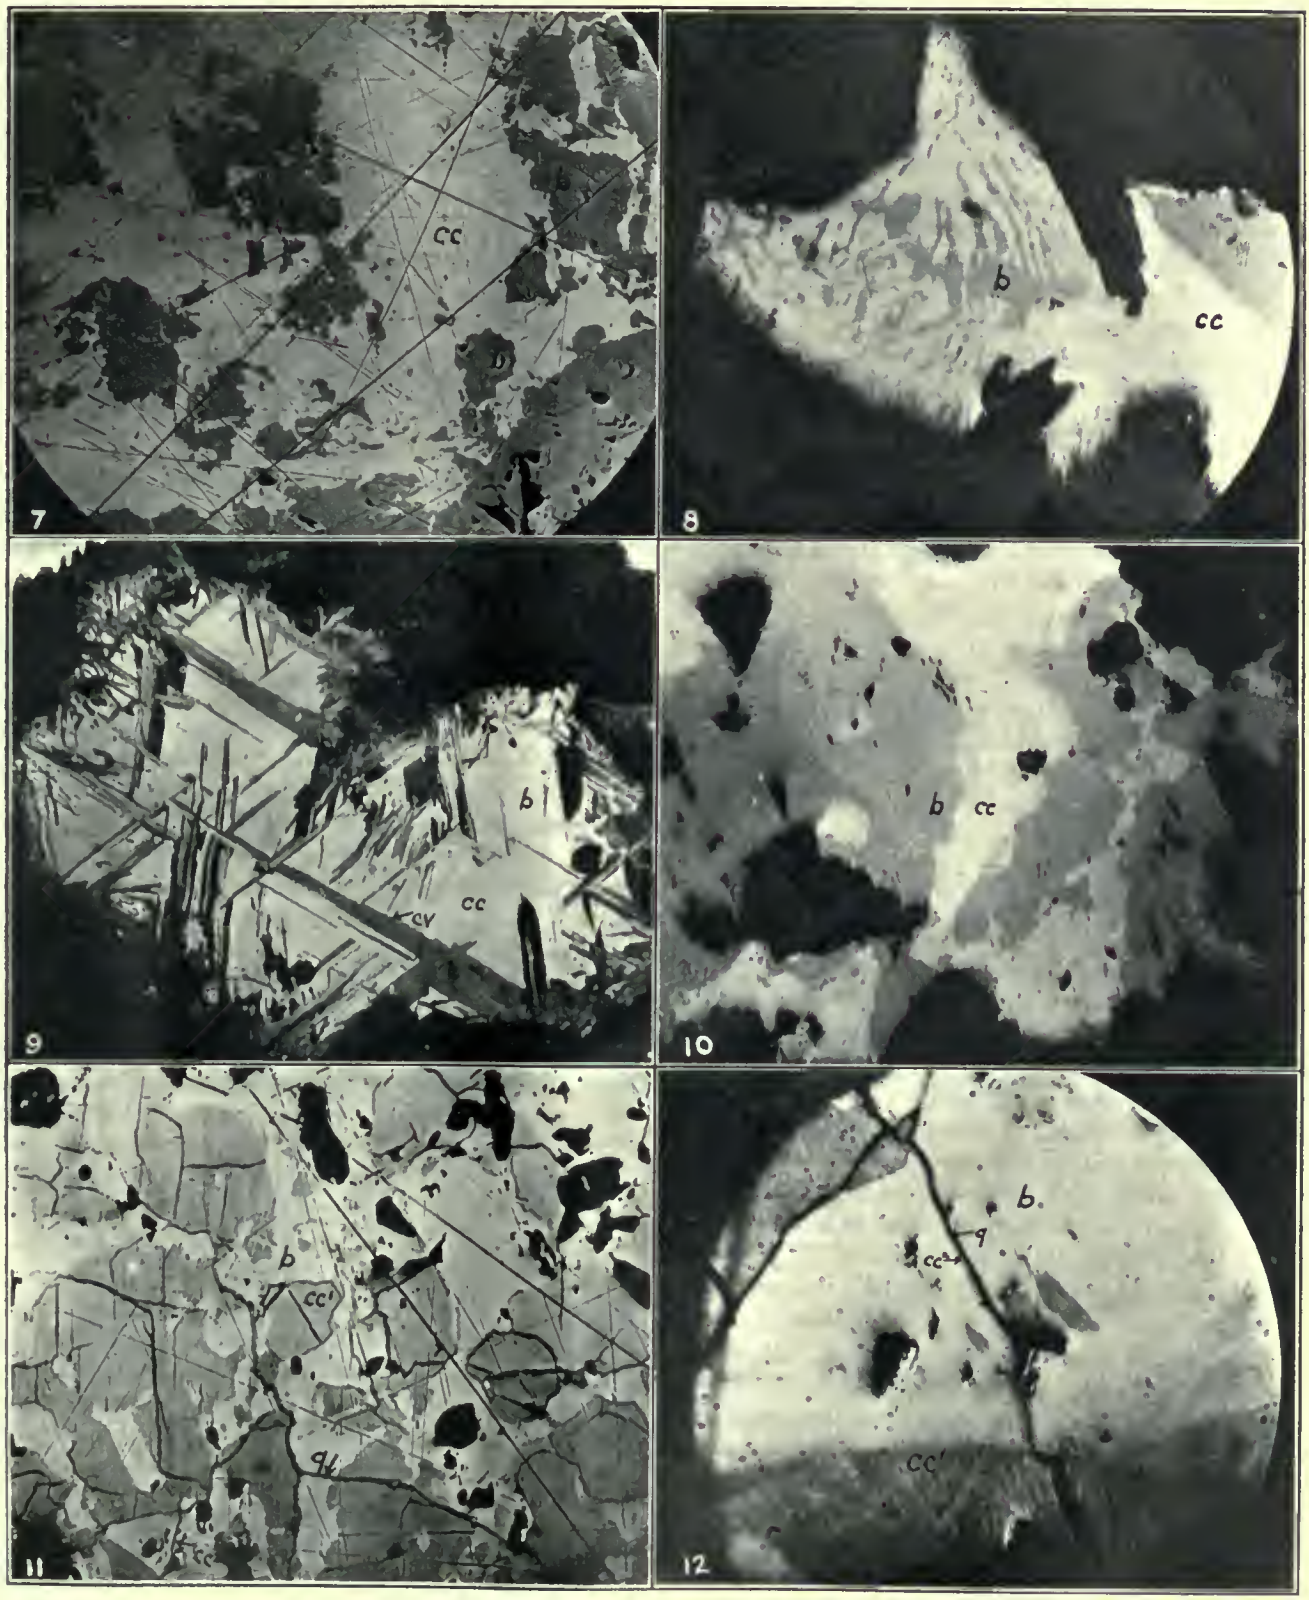

FIG. 7. (× 48) BORNITE (b) ALTERING TO CHALCOCITE (cc). ELM ORLU MINE, BUTTE, MONTANA.

FIG. 8. (× 80) SO-CALLED GRAPHIC INTERGROWTH OF BORNITE (b) AND CHALCOCITE (cc). ENGELS MINE, PLUMAS COUNTY, CALIFORNIA.

FIG. 9. (× 220) COVELLITE (cv) AND CHALCOCITE (cc) FORMED AT THE EXPENSE OF BORNITE (b). ONLY A LITTLE BORNITE REMAINS. ENGELS MINE, PLUMAS COUNTY, CALIFORNIA.

FIG. 10. (× 240) BORNITE (b) ALTERING TO CHALCOCITE (cc). THE BORNITE IS A MAGMATIC MINERAL. EVERGREEN MINE, APEX, GILPIN COUNTY, COLORADO.

FIG. 11. (× 66) SO-CALLED INTERGROWTH OF BORNITE (b) AND CHALCOCITE (cc[1]) WITH QUARTZ (q) VEINLETS BORDERED BY CHALCOCITE OF THE SECOND GENERATION (cc[2]). SNAKE RIVER, FOUR MILES NORTH OF HOMESTAKE, SEVEN DEVILS DISTRICT, IDAHO.

FIG. 12. (× 465) A SMALL PORTION OF LOWER LEFT-HAND CORNER OF FIG. 11 GREATLY MAGNIFIED TO SHOW SECOND GENERATION OF CHALCOCITE (cc[2]) BORDERING THE QUARTZ VEINLETS (q).

[1] and [2] (In figures 11 and 12 the chalcocite appears darker than bornite, on account of the screens used in photography.)

microscopic work of Ray proves conclusively that chalcocite is the result of the metasomatic replacement of other minerals by ascending solutions. A specimen from the 1300-ft. level of the Elm Orlu mine collected by Mr. Ray is illustrated in Fig. 7. This is typical of the high-grade chalcocite ores of this part of the Butte district. The replacement of bornite by chalcocite is very irregular. No anastomosing channels are apparent. The bornite remnants in the chalcocite are irregular and often hook-shaped. The bornite seems to go to pieces almost all at once, for it apparently presents a solid front to the attack of the solutions. Fig. 7 approaches in spots the so-called graphic intergrowth of bornite and chalcocite. This is, in my opinion, not an intergrowth, but a very irregular replacement of bornite by chalcocite. On etching the Butte bornite-chalcocite intergrowth with nitric acid the chalcocite shows uniform orientation over a portion only of the intergrowth. This explains the results that F. B. Laney[45] obtained with the Virgilina specimens. The microphotographs showing the uniform orientation are highly magnified and are only portions of the whole intergrowth. The chalcocite areas with uniform orientation are doubtless skeleton crystals, but there is no reason why skeleton crystals cannot be formed by replacement of another mineral. (Note that in Fig. 9 skeleton crystals of covellite are forming at the expense of bornite which was later changed to chalcocite.) Bornite is probably a solid solution of Cu_2S in Cu_3FeS_3, and this may possibly explain the readiness with which it alters to chalcocite.

In the Engels mine, Plumas county, California, chalcocite occurs with bornite in the so-called intergrowth (Fig. 8). In the specimen from which this photograph was taken there are all gradations from the apparent intergrowths to narrow rims of chalcocite around the bornite. The right side of this figure shows the irregular nature of the replacement of bornite by chalcocite. Above is a very narrow rim of chalcocite, and below is a large area of chalcocite with no residual bornite. It should be emphasized that the bornite in the Engels mine is a magmatic mineral and the probability of the chalcocite also being a magmatic mineral is very slight indeed, for in several specimens it is definitely connected with the introduction of sericite,[46] one of the characteristic hydrothermal minerals. As there is but one generation of bornite, there is practically proof that the so-called intergrowth of bornite and chalcocite is simply an intricate replacement of bornite by chalcocite. But this intricate replacement is one of the criteria of upward secondary sulphide enrichment for at Butte, Plumas county, and Virgilina there is evidence of the formation of chalcocite by ascending solutions.

Figure 9, also from the Engels mine, is a type of replacement of bornite by covellite and chalcocite. Only a little residual bornite remains. The covellite forms along crystallographic directions of the bornite. The variation in the intensity of the covellite is due to a kind of pleochroism, as polarized light is produced by reflection. Fig. 10, representing a bornite and chalcocite mixture at the Evergreen mine, Apex, Gilpin county, Colorado, suggests upward enrichment. This seems probable from the fact that these minerals occur in an igneous dike, though the ores may be due either to magmatic segregation[47] or to an endomorphic contact effect.[48] In Fig. 11, from a mine on the Snake river, four miles north of Homestead, Seven Devils district, Idaho (collected by E. Call Brown), bornite and chalcocite occur in a relation which approaches the so-called graphic intergrowth. This chalcocite is probably formed by ascending solutions at the expense of bornite. The figure shows many quartz veinlets, and while these veinlets undoubtedly indicate descending solutions, they bear no relation to the chalcocite. On high magnification (Fig. 12, $\times$ 465 diameters) the quartz veinlets that cut the bornite are bordered by very narrow rims of chalcocite of a second generation. Here, then, is the superposed effect of downward enrichment upon upward enrichment in the same specimen.

Summary

1. The field study of secondary sulphide enrichment should be supplemented by microscopic study. The microscopic study is valuable, for the field study of an ore deposit is usually limited.

2. Secondary enrichment, especially chalcocite enrichment, is brought about not only by descending solutions, but also by ascending solutions. Upward chalcocite enrichment is probably due to the precipitation of dispersed colloidal copper sulphides brought about by the release of hydrogen sulphide.

3. Though downward enrichment and upward enrichment have certain features in common, such as the occurrence of chalcocite or covellite and often chalcopyrite of the second generation, they may usually be distinguished by careful microscopic study.

4. Criteria of *downward* chalcocite enrichment may be summarized as: (*a*) comparatively regular replacement along anastomosing channels; (*b*) the presence of quartz veinlets related to chalcocite deposition; (*c*) the association of melaconite with chalcocite along veinlets.

5. Criteria of *upward* chalcocite enrichment may be summarized as follows: (*a*) irregular, intricate replacements; (*b*) the presence of so-called graphic intergrowths of bornite and chalcocite; (*c*) presence of sericite related to chalcocite deposition.

Two dredges of the Orsk Goldfields company, Siberia, handled 178,000 cu. yd. in July, yielding $43,000. Tributers recovered $17,300 also. The war has not affected operations.

Oil output of Japan for the first half of 1914 was 992,962 *koku* (945,680 bbl.), against 798,589 *koku* (760,560 bbl.) in the corresponding period of last year.

Upper Yenesei Valley and Adjacent Mongolia

By AN OCCASIONAL CONTRIBUTOR

The Uriankhai region, between approximately 91 and 98° east longitude and 50 to 53° north latitude, is almost entirely unknown to Western civilization, but is likely to attract attention now that Mongolia has made a treaty with Russia and opened her land to foreigners.

The Upper Yenesei basin, or Uriankhai, was visited by Douglas Carruthers in 1910, and his 'Unknown Mongolia' gives a full account of the topography and forest, but, in common with nearly all travelers, he has only a few words about mines; but enough to show that gold and other metals have been mined for many years. Perhaps the most startling features of the country are the dense forests, the *taiga*, almost impassable in the northern portion, and the Uriankhai natives with their herds of reindeer in the higher lands to the south.

ASIATIC SIBERIA AND MONGOLIA, SHOWING URIANKHAI DISTRICT.

The basin of the upper Yenesei, or Uriankhai, comprises an area of about 64,000 square miles, and is watered by the two main heads of the great Yenesei, namely, the Kemchik and the Ulu-Kem, with its two sources, the Kua-Kem and the Bei-Kem. The entire basin drains through a narrow defile toward the Siberian plains. On the north is the Sayansk range, 400 miles long, which merges into the Altai system on the west and is lost in nameless ranges that form the divide between Lake Baikal and Lake Kosogoa on the east. The southern boundary of the basin is Tanna-ola, extending nearly east and west for 350 miles, with flat-topped summits rising to 8000 feet on an average. To the south of the Tanna-ola lie the vast plains of Mongolia, hitherto closed to the miner by the religious scruples of the Mongols, but probably to be opened in the near future.

A report on the mineral wealth of the Uriankhai region has recently been prepared by B. M. Porvatoff, and while the production of this region to date is not significant, the future is promising, and an increased activity is anticipated. It is hardly known whether this land belongs to Russia or China. Very little is known of the mineral wealth of the Uriankhai district, but it is scarcely possible that a territory occupying an area of 64,000 square miles, intersected by the Sayansk range and the Tanna-ola, could be void of mineral resources. The Sayansk mountains, though important, are poorer than the Urals and many other Siberian mining districts.

In Uriankhai only alluvial gold has been exploited. The discovery of gold was made in the year 1839, and until the year 1913 about 379,184 oz., say $6,825,312, of placer gold had been produced. If it be assumed that the Chinese companies and 'poachers' have produced the same amount, it can be estimated that during the past 74 years there has been produced 758,369 oz. of gold, valued at $13,650,624, in the Uriankhai.

The following are the most important mining districts along the Serlich and Siotikem-Algiaki rivers: (1) On the Tapsi river, the Karachem river, and the Baisyuti river, gold is being exploited. On the Karachem river a dredge is now being built. (2) On the Elegest river, at the Chernevitch gold mine, lessees will begin to work this year. (3) On the Teploi river, at Guhanoff and Kazantzieff, placer gold is being produced with hand labor, the sand being washed in buddles and pans. (4) On the Chaidynsik Korallyeh-Kem-Temerchi river, lessees are at work. Besides this, gold sands have been found on the southern slopes of the Tanna-ola range and other parts of Uriankhai.

The characteristic of the Uriankhai alluvial gold deposits is the narrowness of the gold-bearing areas in the valleys and the lack of water in the rivers. During heavy rains and prolonged wet weather the Uriankhai

rivers rise rapidly and become threatening torrents, frequently destroying the surface works on the mines. The rivers at times become dangerous, not only for pack-animals, but also for men on horseback.

Generally the Uriankhai sands are poor in gold. Even such a rich system as the Iliken (Serlich) contains on an average only 50 to 60c. per cubic yard. The gold sands of the Uriankhai district are usually covered with a shallow alluvial turf. The depth of this varies from 6 to 9 ft., with an average pay-streak of 3½ to 6 ft. Where the flood washes away the soil, only a small part of the gold remains in the fissures of the river bed and in the rocks, the greater part being carried away by the floods.

Another peculiarity of the Uriankhai gold sands is that many of the deposits contain platinum with gold as an associated metal. Iridium is found more frequently with gold than with platinum; but, judging from the quantity of platinum produced with gold, it has rather a scientific interest than an industrial one. The question of the possibility of finding industrial platinum in Uriankhai must be proved by further exploration. The absence of any considerable quantity of olivine in the gold sands of the neighboring districts causes one to doubt whether there are platinum deposits of commercial importance.

Uriankhai Gold Sands

Most of the Uriankhai gold sands are capable of being worked by simple methods. Tributers produce a large part of the gold, but until the present this method of working the deposits has not been practised much, because of the distance of the gold-bearing areas from the homes of the workers and the difficult conditions under which the work has to be done. In Uriankhai, where the miners themselves do not work but simply own the ground, the tributers are able to work the gold with profit. With an improvement in transportation to Uriankhai and a larger population, it is certain that gold mining will become an important industry. The hydraulic method is impracticable in the district for lack of water, the absence of suitable places for installing a system of hydraulic washing, and other mechanical difficulties.

The gold veins of Uriankhai were first found in the Amuibsky mountains in 1904. This mine belongs to the Yushkoff company and was called the 'Gift of God.' The production of this mine in three years was 282 oz. of gold, worth about $5000. It proved to be low-grade, and its exploitation soon ceased. There was then discovered a mine on the Quisuik-Chadru river. The owners endeavored to sell it for a fabulously high price, but when examined by a Belgian company it was shown that the deposit was overestimated, and the company declined to buy it. At present it is idle. About the same time, a gold deposit was found near the watershed between the Serlich and the Pokanash rivers. This vein was found to be poor in gold and was subsequently abandoned. The lode deposit of gold on the Talovka with an average gold content of about $10 per ton, is interesting, and if the investigation at depth should yield satisfactory results, this mine promises to be one of the best gold mines in Siberia.

Mention must be made of the asbestos deposits in the basin of the Kemgik river. The asbestos is found in a large serpentine mass constituting a range of hills. This deposit was carefully investigated in the year 1912, when the high quality of the asbestos and the presence of important reserves were established. Besides gold and asbestos, coal, iron, copper, mica, agalmatolite (Chinese figure stone), rock salt, and other minerals, are known to exist in Uriankhai.

Mr. Porvatoff was also able to observe that the region is fairly rich in semi-precious stones. It must be remembered that the district has been very imperfectly surveyed, as Uriankhai is far from any of the known railways or useful waterways, and also far from the principal towns of Siberia. The roads to the nearest town of Minusinsk are poor, so that it is only possible to work the best gold deposits at present.

If one takes into consideration the small Russian and native population of Uriankhai, the low degree of civilization obtaining there, and the low efficiency of Siberian workmen, and other factors on which the success of the mining industry of the country exists, it must be concluded that many of the minerals of Uriankhai must remain unexploited for a long period. The uncertainty of Russia's political relations with Uriankhai and the nebulous state of the frontier question constitute the principal reasons for the absence of a well thought out plan for the exploitation of the whole area. Permission to exploit the mines of Uriankhai down to the present rested on a very uncertain and, in fact, incomprehensible basis. First of all, Russian mining interests could only work the Uriankhai ground for gold, and were not allowed to look for any other mineral. In some parts of Uriankhai, as in Kemchiksky, although claims for gold were admitted, the Russian government had to delay giving the right of exploitation until the frontier question with China had been settled. Further, although the Uriankhai gold miners had complied with all the requirements of the Empire in respect to taxes, they were required to sign an agreement abandoning all claims against the Russian government and to immediately stop work in case the Uriankhai should be declared Chinese territory.

Such a state is abnormal and hampers the development of mining in the country. In view of the frontier question and difficulties in prospecting the district, the Uriankhai officials carefully saw to it that the Russians made no progress.

Labor Question

Another serious difficulty that will be encountered in Uriankhai is the labor question. Workmen will have to be brought from the nearest Siberian villages or districts, and from the interior governments of Russia, which will constitute of itself a cost of about $25 per

head. The local workmen are cattle drivers or nomads. The cost of bringing supplies into the district is also great. The delivery of a dredge at the Saphyanoff property, which cost $52,500 in Petrograd, cost $38,750 to bring it to the ground where it will operate.

It is concluded that the conditions of Uriankhai are at the present unfavorable to mining. No doubt with an improvement in the ways of communication and by colonizing the territory with Russian peasants, the position would be greatly improved. A great expansion in the development of the mining industry in Uriankhai may be expected when the waterway of the upper Yenesei has been carried through and when the Achinsk-Minusinsk branch railway, that has already been authorized by the government, is built and connects Uriankhai with the Siberian trunk line.

For the successful exploitation of the district, it is requisite that the political question respecting the frontier should be clearly established; that the waterway referred to should be promptly made, and steamer traffic on the upper Yenesei established; and last, if the territory should be recognized as Russian, that Russian subjects be allowed to undertake mining operations in the district on the conditions that obtain in other parts of Russian territory.

Uriankhai being a great distance from the Siberian railway and the seaports, low tariffs should be established in order to facilitate the development of the district, particularly on minerals not much used in Russia, but for which a good export market might be established, such as asbestos, mica, vanadium ore, wolfram ore, manganese, and graphite.

Milling at the Camp Bird Mine, Colorado

From the annual report of the general manager, William J. Cox, for the year ended June 30, 1914, the following data are obtained: An average of 25 stamps worked 347.93 days and crushed 30,595 tons of dry ore. The ore yielded as follows:

Metal.	Content.	Value, per ton.	Value, per cent.	Value of output.
Gold, ounces	1.135	$22.91	87.49	$700,880
Silver, ounces	4.270	2.36	9.01	72,206
Lead, per cent	1.324	0.44	1.67	13,378
Copper, per cent	0.260	0.48	1.83	14,615
Total		$26.19		$801,079

The value in the previous year was $22.51 per ton, and the total recovery was valued at $675,630.

The cyanide plant treated 19,344 tons of tailing from the mill, and extracted $39,748. Of the recovery in the mill and plant, the processes were as follows: amalgamation, 52.97%; concentration, 42.07%; and cyanidation, 4.96%; the saving of the gold and silver in the crude ore being 94%. Costs were $1.64 in the stamp-mill, 88c. in the cyanide plant, and $3.10 per ton for bullion and concentrate charges.

Copper Smelting in Canada

Copper production of Canada in 1913 was 34,000 long tons, from over 2,500,000 tons of ore. There are six mining companies operating seven different smelting plants, two in Ontario and five in British Columbia. According to 'The Copper Smelting Industries of Canada,' by Alfred W. G. Wilson, issued by the Department of Mines, there are 29 rectangular water-jacketed copper blast-furnaces in Canada at the present time, the majority of which were in operation when the work was published; some have been blown out since the war started. The total of the hearth areas of these furnaces is 2580 sq. ft., and the rated capacity is 15,600 tons of charge per 24 hours, varying at the plants given, on account of the difference in the ores treated. Details of the furnaces are as follows:

Operating company.	No. of furnaces.	Tuyere dimensions, inches.	Hearth area, square feet.	Ore column, feet.	Capacity, short tons.
Canadian Copper Co.	5	50 by 204	70.83	14	400
" " "	1	50 by 240	83.33	14	550
Mond Nickel Co.	2	50 by 240	83.33	12	550
Consolidated M. & S. Co.	1	42 by 210	61.25	8	350
" " " " "	1	42 by 360	105.00	8	650
" " " " "	1	42 by 264	77.00	8	460
" " " " "	1	42 by 420	122.50	8	700
" " " " "	1	50 by 420	145.80	8	875
Granby Con. M. & S. Co.	6	44 by 266.5	81.41	12	500
" " " " "	2	48 by 260	86.67	12	550
" " " " "	3	50 by 360	125.00	12	750
B. C. Copper Co.	2	51 by 360	127.50	12	800
" " "	1	51 by 240	85.00	12	500
Tyee Copper Co.	1	42 by 120	35.00	6	200
" " "	1	48 by 160	53.33	6	300

There are also several small oval or circular water-jacketed furnaces available, but not in blast on copper ores at present. The Canadian Copper Co. has two Steptoe type reverberatory furnaces with a total hearth area of 4256 sq. ft. The situation of the furnaces tabulated is as follows: Copper Cliff and Coniston, Ontario; and Trail, Grand Forks, Anyox, Greenwood, and Ladysmith, British Columbia. Five of the plants have copper converters. These are as follows:

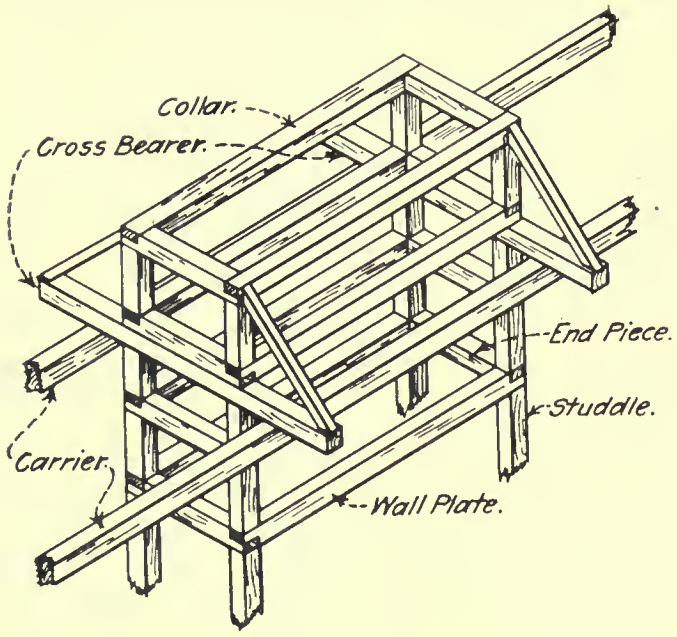
Plant.	Type of converter.	Stands.	Shells.	Dimensions, feet.
Copper Cliff	Basic—Pierce-Smith, special	5	5	10 by 37.16
Coniston	Basic—Pierce-Smith, special	2	2	10 by 25.83
Grand Forks	Basic—Acid shells	3	10	7 by 10.5
Anyox	Basic—Great Falls	3	3	12 by 5.75
Greenwood	Acid—Allis-Chalmers	2	5	7 by 10.5

The work from which these data were abstracted is accompanied by 43 halftones, 39 drawings, and 1 maps.

Shaft Timbering, Mesabi Range, Minnesota

By P. B. McDONALD

The accompanying sketches show timbering in an iron-mine shaft of the Mesabi range in Minnesota, and are typical of practice in that district in cases where no special difficulties are encountered, such as quicksand, but only ordinary comparatively dry overburden. The two bearing pieces or carriers, 40 or 50 ft. long, of 24 or 30-in. timber, were placed in trenches about 10 ft. apart, so that they were parallel with the long dimension of the shaft. They were leveled, and two cross-bearers, 12 by 12 in. by 20 ft., were placed perpendicularly across them 18 ft. apart. The first set was then put in place below the carriers, and the studdles of this set fitted into ½-in. joggles cut in the cross-



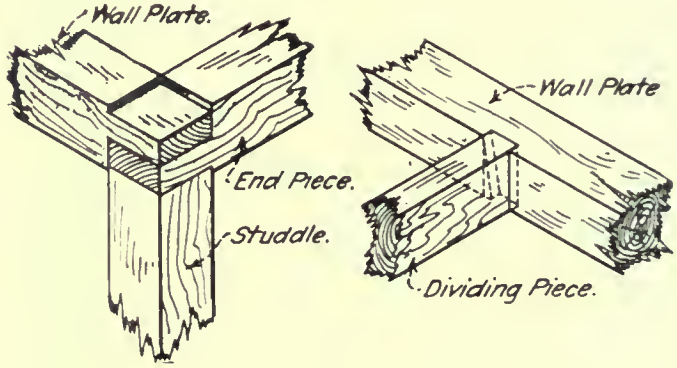
SHAFT TIMBER.

carriers. These studdles were cut so that the distance between the sets was 3 ft. 11 in. The first set below the carrier is, like the other sets, held by four hanging bolts of 1¼-in. round iron. The set which forms the collar was placed above, and was diagonally braced to both sets of bearers; four straight hanging bolts were used here instead of the jointed bolts used in the other sets; and were one foot longer than the regular 6-ft. 8-in. bolts on account of passing through the cross-carriers.

Dirt was hoisted and banked around the shaft collar, where it steadied the timber and kept out surface drainage. The middle compartment of the three into which the space was divided, was used for hoisting during sinking, and was boarded up as fast as the dividers were put in, so that the bucket would not catch. The dividers were put in as the shaft was sunk, but the last two sets were always left open to allow the wall-plates of the next set to be handled. When the end pieces and wall-plates were framed, a strip 2 by 2 in. was spiked on the outside of each piece in the centre to make a bearing for the laths, which are 2-in. plank about 4 ft. 9 in. long, and were put in at the corner studdles first, and wedged, then working toward the middle of the end pieces and wall-plates until there was space for only one lath left.

Four hanging bolts to each set are usually enough, but in heavy ground one or two more is sometimes used in the wall-plates. Divided studdles or centre studdles are put in after the dividers are put in, and since these studdles are not 'gained in' to the wall-plates, small cleats are used to hold them in place.

The second set of carriers are 12 by 12-in. timber, 16 ft. long, and to put them in place, small drifts (about 3 by 4 ft.) are run in about 8 ft. at the ends of the end pieces at two diagonally opposite corners of the shaft. Smaller drifts are run in about 4 ft. at the other two corners of the shaft. The inside corners of these 8-ft. drifts are rounded off and the bottom trued up, and short pieces of plank laid crosswise in them. A bearer is then brought down and one end is run into the 8-ft. drift; next, it is swung parallel to the end piece and the other end is run back into the 4-ft. drift. The same thing is done with the other bearer, and the two rest on the bottom boards of the drift, directly under the corresponding end pieces.



DETAIL OF JOINTS.

Long flat wedges are then driven under the bearers, on top of the boards, and as they are raised against the end pieces the hanging bolts are tightened to take up the weight.

Only light blasting is resorted to in sinking through the overburden, pick and bar work generally sufficing. The weight of the suspended sets of timber becomes an important factor as the shaft gets deeper, requiring other bearers or carriers at intervals, as described above, in addition to the collar set. The intervals between bearing sets or carriers is 25 to 60 ft. The first overburden necessary to sink through to reach bedrock may be as deep as 250 ft. Shaft-sinking on the Mesabi is an expensive operation at best, and usually costs over $50 per foot. If there is much water, this figure will be increased considerably. The shafts are 200 to 500 ft. deep and are vertical. The rock encountered under the overburden may be soft iron ore or broken, silicious, sedimentary formations.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Accident Prevention v. Compensation

The Editor:

Sir—I have been much interested in an article which appeared in your paper of July 11 and which is headed 'Workmen's Compensation Insurance in California.'

During the year 1913 there were killed in the metal mines of this country (and by metal mines, I mean those of precious metals, iron, zinc, lead, and copper) 661 employees. There were serious injuries in the metal mining industries to practically 8000 men; making no mention of minor accidents. Upon a basis of statistics, which I have compiled from many different sources, these deaths and injuries cost the metal mining industries of this country as a whole about $11,560,000 or on the basis of 170,000 men working in this industry in the United States, a tax of $71.35 for each employee. This is considerably higher than even the coal industries or railroads have to bear, so that, dealing with the question of the metal miner, it would look as though the really ultimate solution of this problem is not a question of whether or not a proper basis of taxation to take care of compensation can be found, but of one being forced to reduce the number of accidents. On a basis of 300 working days in the year at $3 per day, the miner would earn $900, and if it cost $71.35 to maintain that miner for the same period, it is going to take about 8% of the payroll to make this compensation.

It is impossible to arrive at any honest basis of computation where only one or two mines are used as an illustration, for the reason that the mines which are advertising their figures are the ones which have phenomenally low death and accident rates. That mine manager who is having bad luck along these lines is not giving out any figures for publication. Everyone knows that as long as there is a mining industry, there is going to be a certain percentage of unfortunate instances which will take the lives of men or maim them.

There is no question but that in mining exactly the same condition prevails as in all other classes of work, namely, that probably 70% of these accidents are due to carelessness, and that carelessness may possibly be on the part of the mine manager, superintendent, or foreman as well as the employee. It seems to be a peculiar condition that all branches of mining work are covered by thoroughly trained technical and practical men except this one of accident prevention. The laws of our different mining states have provided inspectors whose duty it is to go around and offer suggestions, but how frequently does it happen that even when his suggestion is made, it is pigeonholed as being impractical or too costly. I remember a number of years ago, when holding a position as timekeeper for a certain large mine, a serious accident happened in which 15 men lost their lives. This particular accident was in a shaft, and a great deal of secrecy was maintained after the investigations were made. Somewhere along the line, recommendations by the state inspector had been absolutely disregarded. I do not attempt to say that if these recommendations had been followed the accident would not have happened, but it did develop that somebody had overlooked or absolutely ignored these recommendations.

After the accident, which shut this mine down for many days, cost thousands of dollars to settle, and in a measure disorganized a working force of nearly 500 men, and had its effect on the entire mining community, it was found that an expenditure of possibly not to exceed $1500 to $2000 in proper appliances between the collar of that shaft and the sheave wheels, would have prevented the accident. In this case, the door was locked after the horse was stolen. Those safety appliances are now, and have been for several years, kept in excellent shape. This, I will admit, is an extreme case, but, unfortunately, in the large majority of cases where men are killed and injured it is only the very extreme cases that come to anybody's attention.

How many men are killed in the mining industry in a year's time from disregarding the proper use of tamping bars? How many men are killed and injured from the improper use of cages, of disregarding instructions regarding the handling of bell cords and signals underground, the improper care of electricity, and many other cases which can be enumerated?

This is, to a certain extent, the fault of the management, not because it does not suggest and as far as possible protect, but because shift-bosses and superintendents are prone to overlook a man's carelessness because of the breadth of his shoulders. They gamble the lives of the men under them against a man's ability to do a little more work than the careful man because the monthly report fails to show the cost per ton under the head of accidents and legal service. The mining industries of this country have had an enormous amount of teaching along the line of 'first aid to the injured.' What we need now is a department of 'first aid to the uninjured.'

For some reason or other, it has been felt that as long as the mine paid its premium to the liability insurance company, its duty was fulfilled and if an accident happened the company was amply protected and the widows

and orphans would be taken care of, but everyone knows that no amount of money will ever compensate for the misery and the degradation that is caused when the wage earner of the family is gone.

There was recently formed in the city of New York, to deal with this subject, the American Mine Safety Association. The probabilities are that this Association will have a hard time to get the different mining companies in this country to join, and yet there is not the least doubt that if this Association were given the undivided support of the mining industries, in ten years time the progress made and the lives saved would be simply astounding. Here, without any doubt, is a great deal of the solution of this question of workmen's compensation. What is needed in the mining industry is more prevention and less attempt at financial cure.

Valuation of Dredging Ground

The Editor:

Sir—Mr. Hohl, in his letter on the valuation of dredging ground, in your issue of September 26, solves a different problem from that proposed by Mr. Decoto, since he has substituted a value of $1.60 per yard for hole No. 7 in place of 60c. as stated in Mr. Decoto's original diagram.

The solution suggested by E. B. Thornhill (July 18)

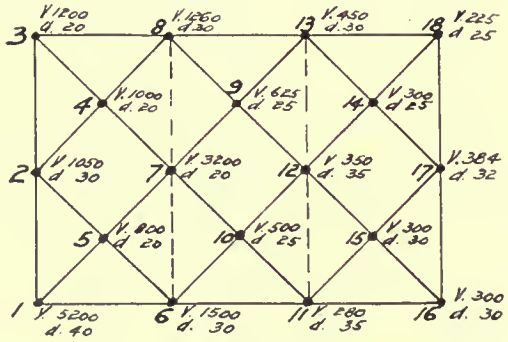

FIG. 5. FROM MR. HOHL'S DISCUSSION.

and by myself (June 27), is based on the diagram, assuming that Mr. Decoto's use of the value $1.60 in his calculation was a clerical error, so that it would be unfair to compare results on this basis with those of Mr. Hohl. Assuming the value of hole No. 7 as $1.60, as in Mr. Hohl's Fig. 5, in order to compare results on the same basis, and calculating by the method outlined in the letters last referred to, gives for the area 1-3-8-6 an average value of 65.42c., and for the whole area a value of 34.97c. per yard, against Mr. Hohl's values 69.6, 67.9, 70.8, and 35.8c., and Mr. Decoto's values, 72.42 and 37.64 cents.

The point raised with respect to the method used by Mr. Decoto is that it takes no account of the relative volume of the deposit represented by each drill hole as do both the other solutions. Mr. Hohl's method of getting the average value of part volumes evidently makes his result the most reliable of the three, but it seems that his method as outlined in his letter applies only to the usual case of holes spaced at uniform intervals, so that it should not be applied to irregularly spaced holes without due consideration. A discussion by Mr. Hohl of conditions in an area having holes spaced closer in one part than elsewhere would be of interest.

The Hall Process

The Editor:

Sir—I would like to say one word concerning your editorial appearing in the issue in which my article on the experimental development of the Hall process was published. I was extremely frank in what I said, and I believe in being so, nevertheless some of the suppositions which you make concerning the patent situation should, I feel, be answered. Our people have, naturally, delved deep into this question, and the best patent opinion which we have been able to secure on both sides of the water makes us feel very comfortable, whether the reduction of the SO_2 is accomplished by H_2S or by hydrocarbon compounds admitted as fuel into the furnace. The essential points as developed and lucidly portrayed in our patent specifications are so fundamentally different from the Thiogen process, for instance, that no interference between the two is possible. I am writing you thus, simply to correct any impression that might be given by your editorial that our patent situation is weak. It is distinctly strong, and besides this, I trust that the policy which we hope to pursue in gradually getting the process adopted and perfected will be sufficiently broad that the metallurgical fraternity will find no reason or temptation to attack the patents.

HOWARD F. WIERUM.

New York, October 19.

Economical Sliming in Grinding Pans

The Editor:

Sir—In my article published in the *Press* of May 23, a word has been omitted on page 847, which makes one sentence quite unintelligible. Instead of "* * * and after being treated on these tables the pulp overflow from classifiers and cones was made to pass an automatic sampler * * *," the sentence should be read: "* * * the pulp, *inclusive* overflows from classifiers and cones," etc. I made special reference to this, because I wanted it to be understood that all the material treated went through the samples, and that no fine material could escape from the mill unnoticed in overflows.

M. G. F. SÖHNLEIN.

Ingenio de Machacamarca, Bolivia, S. A., June 27.

SILICA OUTPUT of the United States in 1913 was 232,192 tons, valued at $953,832.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

REVENUE of the Panama canal in August was $91,664, most of which was collected after the 15th. To September 1 the earnings totaled $118,129.

SMITHSONITE, OR CARBONATE OF ZINC ORE, used almost exclusively in the manufacture of white oxide, occurs in extensive deposits in the northern parts of the Platteville, Wisconsin, zinc district.

'ALBOLINE' AND 'PETROLATUM OIL' are petroleum distillates imported from Baku, Russia, but oil from United States wells will yield these same medicinal articles, and have, in fact, been produced in this country in small quantities for many years.

NINETY-TWO dredging plants in Victoria, Australia, handled 16,706,023 cu. yd. of gravel averaging 7.2c. per yard in 1913. The Briseis company of Tasmania was the largest operator, with four boats, treating 1,461,200 cu. yd., yielding 8.2c. per yard.

PARAFFIN WAX, a petroleum product, was exported from the United States to the value of $9,000,000 to $10,000,000 during the past three years. Natural mineral wax, ozocerite, with a high melting point, is imported from Galicia, Austria; but it occurs and is produced in Utah. Reduction of the mineral is expensive.

SPARES used at the five stamp-mills (240 stamps) of the Oriental Consolidated in 1913 were as follows: shoes, 655; dies, 451; bosses, 10; tappets, 31; cams, 6; stems, 7; cam-shafts, 7; and quicksilver, 24,000 oz. Chemicals used at the five cyanide plants were as follows: cyanide, 185,395 lb.; zinc and zinc dust, 541,168 lb.; borax, 37,408 lb.; lime, 986,942 lb.; and soda, 4608 lb. A total of 301,162 tons of ore was crushed, and 48,117 tons of concentrate cyanided.
